Welcome

Dear ECSS Paris 2023 Participants,

ECSS returns to its country of birth for its 28th annual congress – 27 years after its first edition in Nice. On behalf of the Paris team, we are honoured to have the opportunity to help you discover or rediscover the City of Light while attending this fantastic event!

We hope you will spare some time before and after the congress to feel the 'Parisii spirit' – a Gallic tribe that dwelt on the banks of the River Seine during the Iron Age and the Roman era. Step into these past times by walking, biking or running along the River Seine to discover the most beautiful monuments of Paris from the cathedral Notre Dame (under reconstruction) to Alexandre III Bridge, the Invalides or even the Eiffel Tower, which you will see during the Bengt Saltin Run. After an enjoyable run, you may want to do your active recovery walking around the quartier latin between the Pantheon and La Sorbonne under the students' eyes. Perhaps you will have your shower or hammam on the rue Geoffroy-Saint-Hilaire.

After visiting the capital's top attractions, why not take a look at some of the favourite spots of Parisians: districts they stroll through on the weekend, parks where they picnic, their famous café terraces for breakfast or an aperitif. Take a green interlude in 24 hectares of the Jardin des Plantes and then cross the river to discover the arrondissement Popincourt, between Bastille and République – one of the most densely populated urban districts of any European city. You may have lunch in the Marais where the United Excellence of Sport Science reception will take place, full of fashionable cafés, restaurants, nightlife, and a range of boutiques and galleries. If you head north-west along the Boulevard Richard-Lenoir, you will reach the romantic Canal St-Martin which was a former route for wood supplies. If you prefer to take the high roads, you can choose one of the hills in the North of Paris (Charonne, Belleville, Bergère, Ménilmontant or of course Montmartre and the Sacré Coeur) where you can admire fantastic viewpoints. In these neighborhoods, you will encounter art at every turn, whether it's street art, buildings with amazing architecture, outdoor works of art and high-profile movie locations – art is everywhere in the French capital.

Together with these unique gifts Paris has to offer, we are looking forward to opening a pre-Olympic and Paralympic forum at INSEP and the Palais des Congrès, both connected by the historical axis and the métro Line 1. You may want to attend the Elite Sport Performance satellite at INSEP on the afternoon of Monday 3 July, which will end with a public lecture from the well-known French athlete and explorer Stéphanie Gicquel, who was designated as the best French athlete in 2022. Please do not miss the ECSS-IOC joint symposium, where high profile researchers will share their work developed in the IOC Research Centres for the Prevention of Injury and Illness. The Masterclasses aimed at students this year will include for the first time a Data Visualisation session led by young scientists and data analysts. In addition, starting from Wednesday, we will have the chance to discover an outstanding scientific programme covering the most exciting areas of sport science. Last but not least, and as a result of our close work with partners and local authorities, we will have a number of exciting social events that will take the congress to unique sites around the city and offer an unforgettable experience for ECSS Participants!

You are warmly invited to enter the doors of the City of Light and be a part of the Olympic and Paralympic journey.

Paris vous attend! / Paris is waiting for you!

Yours in Sport Science,

The ECSS Paris 2023 Organising Team

IS-AP01 Recovery and sleep in elite sport

MONITORING SLEEP IN ELITE ATHLETES AND INTERVENTIONS TO ENHANCE SLEEP

HALSON, S.

AUSTRALIAN CATHOLIC UNIVERSITY

Sleep is considered the best recovery strategy available to athletes and has important roles in physical and mental performance, illness and injury prevention, mood, metabolism and cognitive function. Research has established that athletes face numerous sleep challenges and have reduced sleep quality and quantity when compared to the general population. Alongside the rapid increase in research in sleep and athletes is the proliferation of wearable devices to assess sleep. The latest scientific knowledge regarding sleep measurement tools will be provided, including validation research, specific metrics provided by wearables which have sufficient validity and relevance to athletes, and availability, security and access to data. Important caveats for consideration when using these devices with athletes will be presented. Further, is important to understand how to appropriately use metrics derived from wearables and activity monitors to improve sleep. Feedback and behaviour change strategies form essential components of athlete monitoring and education, with scientific evidence developing in this area. Other strategies to increase sleep in athletes, including nutritional and psychological strategies will be outlined.

INFLUENCE OF CHRONOTYPE, TRAINING/COMPETITION SCHEDULES, AND DAYTIME NAPPING ON ELITE ATHLETES SLEEP

VITALE, J.

IRCCS ISTITUTO ORTOPEDICO GALEAZZI

Sleep disturbances in athletes may be explained by their constant exposure to many stressors that impair sleep. Among these variables, also training and competition schedules may influence the sleep response to exercise. Late evening or night competitions, that are very common in team sport disciplines (eg: soccer, basketball or volleyball), can have a negative impact on athletes' sleep onset latency and sleep efficiency. On the contrary, early morning training sessions can reduce total sleep time leading to a sleep debt, especially in athletes of individual sport disciplines (eg. runners, race walkers, triathlon athletes). In addition, athletes have different chronotypes with morning-type athletes displaying early sleep-wake cycles and evening-types athletes showing a strong predisposition toward eveningness. In this context, daytime naps are important tools to offset the adverse impacts of inadequate sleep. Napping during the day can increase the amount of sleep obtained in a 24-hour period and many athletes report including daytime napping in their training program. With the present talk, napping characteristics and the impact of naps on various measures of athletic performance in athletes will be discussed.

EFFECT OF SOCCER CONGESTED SCHEDULE ON PERFORMANCE AND INJURY RISK: THE RELEVANCE OF RECOVERY

DUPONT, G.

CELTIC FC

During periods where the schedule is particularly congested (i.e. two matches per week over several weeks), the recovery time allowed between two successive soccer matches lasts 3-4 days, which may be insufficient to restore homeostasis. Alternating between domestic, continental and international matches during these periods may additionally lead to exhausting travel stress and sleep restriction. As a result, players may experience acute and chronic fatigue potentially leading to injury. There is a lack of scientific data to date examining the specific role of sleep restriction on the risk of acute injury. Available evidence suggests that post-match sleep restriction may result in fatigue, reduction in muscular strength, change in mood and altered cognitive functioning the following days, which may affect attention and decision-making skills during ensuing training sessions and matches, potentially resulting in injury risk increase. With the present lecture, we will discuss the interest of implementing, during a congested schedule, a recovery monitoring protocol including questionnaires, sleep records and physical tests in order to help practitioners preventing injuries.

OP-BM01 Biomechanics and Motor Control

COMPARING COUNTERMOVEMENT JUMP FORCE PRODUCTION AFTER ANTERIOR CRUCIATE LIGAMENT RECONSTRUCTION TO PRE-INJURY PERFORMANCE USING STATISTICAL PARAMETRIC MAPPING

DE FRANCA, C., BAYNE, H., JORDAN, M., BOTHA, T.

UNIVERSITY OF PRETORIA, SOUTH AFRICA

INTRODUCTION: Force-time analysis of a bilateral countermovement jump (CMJ) is used to detect neuromuscular deficits after anterior cruciate ligament reconstruction (ACLR). The uninvolved contralateral limb is often used to benchmark recovery along with discrete force and impulse metrics. Both practices may be incomplete indicators of recovery as injury affects strength in the contralateral limb, and discrete variable analysis may exclude force production over the full range of motion in jumping. This study addresses these gaps by investigating changes in CMJ force production after ACLR compared to a pre-injury baseline and inclusion of statistical parametric mapping (SPM) as well as discrete variable analysis.

METHODS: Ground reaction forces were recorded for 12 (male n = 6, female n = 6, age = 21.6 ± 3.7 years) elite multisport athletes on dual force plates (1500Hz) during routine CMJ testing pre-injury (T0), and at 24 ± 3 weeks (T1) after ACLR. Raw force-time data were processed and analysed in the Shiny Vertical Jump Analysis app (https://github.com/mattsams89/shiny-vertical-jump) in Rstudio for the unweighting, braking and propulsive phases of the CMJ. Paired t-tests, asymmetry index and SPM were used to compare the involved limb and uninvolved limb after ACLR, and compared to T0.

RESULTS: At T1, peak force was reduced on the involved limb (T1: 6.4 ± 1.6 N/kg; T0: 7.7 ± 1.4 N/kg, p = 0.002), with greater inter-limb asymmetry for peak force (T1: 7.3 ± 11.1%; T0: -1.1 ± 6.1%, p = 0.039) and propulsive impulse (T1: 12.3 ± 13.3%; T0: -0.2 ± 4.8%, p = 0.011). Propulsive impulse of the uninvolved limb increased from T0 (1.33 ± 0.11 N.s/kg) to T1 (1.58 ± 0.55 N.s/kg, p = 0.037). Propulsive impulse was significantly lower for the involved versus the uninvolved limb at T1 (p = 0.021). SPM showed lower vertical force production for the involved limb when comparing T0 to T1 (p<0.001) from 92% to 99% of the entire CMJ movement; and for the involved versus uninvolved limb (p = 0.009) from 72% to 76% of the entire CMJ movement at T1.

CONCLUSION: Both the discrete variable analysis and SPM revealed a reduction in the involved limb force and impulse production, resulting in elevated inter-limb asymmetry six months after ACLR compared to pre-injury. However, SPM analysis identified additional temporal force-time deficits compared to discrete time point analysis. This highlights the need to consider post-surgery knee function across all phases of centre of mass acceleration and lower limb joint position. Greater propulsive force production of the uninvolved limb post-surgery versus pre-injury may indicate a training effect of the uninvolved limb, or an adjustment in movement strategy. Utilising pre-injury baseline and assessing the shape of the force-time waveform and timing of peak force rather than relying only on discrete or phase-specific metrics may be more useful to assess force production after ACLR to better inform rehabilitative programs and guide return to play.

INFLUENCE OF FATIGUE AND COGNITIVE LOAD ON LANDING BIOMECHANICS IN HEALTHY AND CHRONIC ANKLE INSTABILITY PATIENTS

DURY, J., MICHEL, F., RAVIER, G.

UNIVERSITY OF FRANCHE COMTE

INTRODUCTION: Sports performance implies cognitive and physical load. These constraints impair human movement as jump landing and could increase risk of injury particularly in individuals with injury history. Among sport injuries, ankle sprains are one of the most frequent and imply long term consequences as chronic ankle instability (CAI). The understanding of factors that could predispose to ankle sprain is essential to the development of relevant prevention programs. Nevertheless, there are few studies investigating the impact of both cognitive load and fatigue on a jump landing, particularly in CAI patients. Therefore, the main objective of the study was to determine the influence of fatigue and cognitive load on the landing biomechanics in both CAI and healthy subjects.

METHODS: Twenty-three voluntary males, 13 healthy and 10 presented a CAI participated in this study. They performed single leg landing before and after a fatiguing protocol; with and without adding a cognitive task. The fatiguing protocol consisted of 4 exercises involving jumps and changes of direction performed until a 20% decrease in isometric plantarflexion strength. The cognitive task consisted of tracking a ball on a screen that moved in 2 dimensions among 9 distractor balls. The landing was performed on a force plate that allowed to measure ground reaction force (GRF) and time to stabilization (TTS) in vertical, anteroposterior (ap) and mediolateral (ml) axes. Furthermore, three dimensional movements of the hip, knee and ankle were recorded using infrared cameras system.

RESULTS: CAI group presented a greater GRF (p=0.044) and TTS (p=0.003) in vertical axis and greater GRF in ap axis (p=0.028) than healthy subjects. Fatigue induced a decrease in plantarflexion (p<0.001), ankle supination (p=0.044), hip abduction (p=0.038) and GRF in vertical axis (p=0.004). Furthermore, fatigue conducted to an increase in knee flexion (p=0.001), knee abduction (p=0.047), hip internal rotation (p=0.49), GRF in ml (p=0.016) and TTS in ap (p=0.010). Finally, dual task implied decrease in ankle internal rotation (p=0.006) and increase in knee flexion (p=0.028), knee abduction

(p=0.042), hip flexion (p=0.020), GRF in ml (p=0.019) and TTS in the three axes (p<0.001). There was no interaction between group, fatigue or cognitive factors.

CONCLUSION: The higher GRF and TTS observed in CAI group confirms the existing biomechanical differences between both groups that could predispose CAI subjects to recurrence. Surprisingly, there is no interaction between group, fatigue and cognitive factors. Nevertheless, the increase in the range of motion of knee and hip reveal a more proximal control of jump under constraints conditions as fatigue and cognitive load. In addition, the longer time to stabilization observed in fatigue and dual-task conditions indicates impairments of dynamic postural control. Thus, cognitive and fatigue do not appear to increase specifically the risk of ankle sprains but involve alterations on whole lower limb.

HUMAN FOOT MUSCLES STRENGTH AND ITS ASSOCIATION WITH ACCELERATION SPRINTING, CUTTING AND JUMPING PERFORMANCE KINETICS IN HIGH-LEVEL ATHLETES

TOURILLON, R., MICHEL, A., EDOUARD, P., FOURCHET, F., MORIN, J.B.

UNIVERSITY OF SAINT-ETIENNE, FRANCE

INTRODUCTION: The human foot is composed of intrinsic and extrinsic foot muscles that dissipate and generate net center of mass energy during rapid tasks such as running, jumping or hopping. In addition, it acts also as an efficacious lever during propulsion allowing rapid transfer of ankle plantar flexors forces into the ground. If this energetic and biomechanical role is indisputable, the literature pertaining to the relation between human foot muscles strength and sport performance is not well established. Therefore, the main aim of this study was to understand the relationship between metatarsophalangeal joint (MTPj) flexion strength and sprint acceleration, cutting and jumping performance and kinetics.

METHODS: In fifty-two high-level athletes (n=5 females, 20.1±2.1yrs, body mass index (BMI) 23.2±3.1) we assessed Foot Posture Index, foot passive stiffness using the Arch Height Index Measurement System and MTPj maximal isometric flexion torque using a custom-built dynamometer with a 6-components force sensor. Ankle plantarflexion and knee extension isometric torque were assessed using an isokinetic dynamometer whereas kinetic variables were assessed during sprinting, 90° cutting, foot-ankle hopping and vertical and horizontal jumping using a ~5.4-m force platforms system. Stepwise backward multiple linear regressions were used to understand the relationships between all the aforementioned variables.

RESULTS: During maximal speed phase we found a significant contribution of MTPj flexion strength and foot passive stiffness to explain effective vertical impulse (adjusted r^2=0.28, p=0.008) and a contribution of MTPj flexion strength and foot-ankle reactive strength to explain contact time (r^2=0.35, p=0.003). Interestingly, the association of ankle plantarflexion isometric torque and foot passive stiffness was significantly associated with propulsive impulse during early acceleration (r^2=0.31, p=0.005) whereas ankle plantarflexion isometric torque and foot-ankle reactive strength were associated with cutting performance (r^2=0.35, p<0.001). No other significant relationships were found between MTPj flexion strength and performance or kinetics in cutting and jumping task.

CONCLUSION: These findings show the contribution of MTPj flexion strength and foot passive stiffness (28% and 35% of the variance explained, respectively) to effective vertical impulse and contact time when running speed reach its maximal value. Accordingly, the foot might be a factor to consider for sprinting performance due to the importance of a large ground reaction force production over a short contact time at high maximal speed. Finally, ankle plantar flexors strength and foot-ankle reactive strength seem to explain ~33% of the variance in cutting performance and propulsion during early acceleration. This study highlights that the foot-ankle strength capability has a greater influence on horizontally-oriented explosive movements than overall vertically-oriented ones.

CAUSAL ROLE OF PREFRONTAL CORTEX IN MOTOR LEARNING AND COGNITIVE PROCESSING: A RANDOMIZED, DOUBLE-BLINDED AND SHAM-CONTROLLED BRAIN STIMULATION STUDY

PRABHU, N.1,3, LEHMANN, N.1,3, TAUBERT, M.1,2,3

1 OTTO VON GUERICKE UNIVERSITY MAGDEBURG; 2 CENTRE FOR BEHAVIOURAL AND BRAIN SCIENCE MAGDEBURG; 3 COLLABORATIVE RESEARCH CENTRE 1436-C01 MAGDEBURG

INTRODUCTION: It is commonly assumed that the positive impact of motor behaviour on cognition is mediated by brain plasticity, but causal evidence for this claim is still missing [1]. Using neuroimaging, we were previously able to observe structural plasticity in the prefrontal cortex (PFC) when participants learned a complex whole-body balance task over six consecutive weeks [2]. However, the exact role of the PFC for balance learning and cognitive performance remains unclear. Here, we tested the hypothesis that non-invasive brain stimulation of the PFC network modulates motor learning [3], performance variability [4] and associated cognitive transfer [5].

METHODS: In a randomized, double-blinded and sham-controlled study, participants (n = 44, 21.8 ± 3.25yrs, 27 females) received cathodal transcranial direct current stimulation (c-tDCS) over the right PFC (20 min of stimulation, intensity: 1mA, current density: 0.028mA/cm2) during training of a complex dynamic balance task (DBT) [2] over three weeks (two sessions/week). Motor learning and performance variability were measured using time in balance (±3 degrees to horizontal) [2] and coefficient of variation, respectively. Before and after the 3-week learning phase, cognition was assessed with PFC-related tests: the trail making test (TMT), a measure of planning, cognitive flexibility and attention [6] and the Eriksen flanker task, a measure of interference resolution [7].

RESULTS: In line with previous findings [2], both groups showed significant DBT performance improvements across the six practice sessions. C-tDCS had no effect on learning (group x time interaction effects: F(5, 18.66) = 1.29, p = .31, d = 0.4;

mixed ANOVA based on trimmed means), but resulted in significantly higher performance variability during learning compared to sham tDCS (group x time interaction effect: F(5, 19.4) = 2.9, p = .04, d = 0.5, medium effect). C-tDCS also tended to induce a larger improvement in TMT-part B performance (t(41.49) = 1.89, p = .07 (Brunner-Munzel test), Cliff's d = 0.3, small effect), and reduced improvement in the accuracy of the Eriksen flanker task compared to sham (t(41.83) = 1.93, p = .06, Cliff's d = 0.3).

CONCLUSION: Our results provide causal evidence for PFC network involvement in long-term DBT practice. We interpret the observed tDCS-effects on motor and cognitive performance as evidence for a potential overlap between the neural substrates for complex motor learning and cognitive processing within the PFC-SMA network.

A NOVEL FRAMEWORK FOR THE ANALYSIS OF LINEAR ACCELERATION MECHANICS FOCUSSING ON 'SHIN ROLL': HOW TO ROCK N ROLL'?

OEPPERT, T.J., ZEDLER, M., GOLDMANN, J.P., BRAUNSTEIN, B., WILLWACHER, S., ALT, T.

GERMAN SPORTS UNIVERSITY COLOGNE

INTRODUCTION: The generation of horizontal force is essential for sprint acceleration. It requires a precise sequence of joint kinematics and kinetics, which is elicited during swing-stance transition [1]. Thirty years ago, the effectiveness of a 'rotation-extension strategy' has been emphasized: a rotation of the centre of mass (CoM) around the foot in the early stance, followed by a delayed extension of the hip (HJ), knee (KJ) and ankle joint (AJ) [2]. As the rotational component is vital for horizontal acceleration, a deeper understanding is necessary. Therefore, this 'Method and Theoretical Perspective' article aimed to introduce a novel framework which identifies key positions and a temporal sequence of movement strategies contributing to efficient acceleration.

METHODS: A 3D analysis using 16 infrared high-speed cameras (250 Hz, Vicon, Oxford, United Kingdom) was used to study the first three steps of nine female elite sprinters (23±5 years, 172±5 cm, 61.5±5.0 kg, 100 m-PR: 11.4±0.2 s). Combined with a review of existing evidence, this dataset led to the identification of a framework based on the shins' orientation in space [3].

RESULTS: A continuous forward rotation of the shin towards the supporting ground (SG) ('shin roll') was observed from late swing to late stance. Three movement strategies drive the shin's downward tilt and connect four key positions. The 'shin block' defines the instance during late swing at which the shins' rotation direction changes. The athletes then reach the 'touchdown' (initial ground contact), by way of the 'shin alignment' strategy. This is followed by the 'heel lock' when the AJ reaches its lowest position through the 'ankle rocker' strategy. Finally, the 'propulsion pose', defined as the minimum shin angle in relation to the SG, is achieved via the 'shin drop' strategy.

CONCLUSION: The 'shin roll' facilitates rotation of the CoM prior to proximal-to-distal energy transfer. The 'shin alignment' strategy, achieved through a HJ extension with a 'locked' KJ, enables an efficient interaction with the SG after touchdown. Following rapid heel stabilization, the shin continues to rotate forward through a pronounced AJ dorsiflexion ('ankle rocker'). These strategies, as supported by previous research [4] associating foot placement posterior to the vertical projection of the CoM and greater AJ dorsiflexion range of motion during early stance with improved acceleration performance, assist in quickly overcoming the braking impulse. The 'shin drop' ensures a considerable amount of maintained flexion in the AJ and KJ, decreasing excessive vertical acceleration. By combining the ankle rocker and shin roll, the cue 'Rock n Roll' offers a catchy association for practitioners. The framework helps improving the technical understanding of sprint acceleration and can be used as a template for future research.

Blasco-Lafarga, C.1

INTRODUCTION: Coordination of the diaphragm with abdominal muscles increases intra-abdominal pressure, favoring trunk stabilization, which helps to maintain postural stability in situations of destabilization by external forces or during reactive or dynamic tasks (1). Impaired diaphragm functionality is associated with impaired balance (2), which may increase risk of falls in elderly population, who also tend to have reduced inspiratory muscle strength (IMS) (3). Inspiratory muscle training (IMT) is low cost and has proven to be effective in healthy elderly improving IMS and balance (4) but training proposals focused on this population do not contemplate it. Nordic walking (NW) is a good strategy, not only because of the conditional improvements, but also because it could cause greater adherence since it is done outdoors and can even be combined with other training programs (5). Since both programs improve balance and have never been used together, this study aims to analyse changes in IMS and balance, after 8-weeks of NW+IMT program.

METHODS: Forty-nine elderly were recruited from May to December 2022. Eighteen complete final sample and were divided into two groups:sham (69.24±4.59yr;72.32±11.65Kg,n=9) and experimental (68.43±4.33yr;71.03±9.93Kg,n=9). IMT (unsupervised), specifically inspiratory pressure threshold loading, involved 30 inspirations, twice daily, 7 days/week at 50% (experimental) or 15% (sham) of IMS, while NW (supervised) was 1 hr, 3 days/week. S-Index, mini-BEST test, blood pressure and body composition were assessed before and after intervention. To find out differences between groups after intervention, two-way ANOVA repeated measures or Wilkoxon test were used according to the sample normality.

RESULTS: IMS and balance improved in two groups ($p<0.001$ & $p=0.015$) but analysis considering groups only showed significant differences in experimental (IMS:$F=15.957$;$p=0.001$;$\eta 2=0.499$; OP=0.943 & balance:$p=0.020$;ES=0.081).

CONCLUSION: This is the first study combining NW+IMT. Regardless of inspiratory training load, 8-weeks of NW+IMT program are enough to improve IMS and balance, however, considering groups only experimental group improve significantly. NW is known for improving balance and mobility in elderly, so this was expected in both groups. IMS improvement, although not significant in the control group, could be due to a better recruitment of motor units and better coordination of the inspiratory muscles (6). However, in experimental group they are larger and significant, probably because structural adaptations related to the training load also occur. This confirms that improvement in inspiratory strength enhance the effects of NW on balance. Therefore, this combination should be considered as a strategy in prevention of falls, one of the main causes that lead older adults to hospitalization.

UNIVERSITY OF VIENNA

INTRODUCTION: The ability to produce muscle power is reflected by the force-velocity (F-V) relationship. Aging is associated with neuromuscular remodeling processes that result in reduced maximum shortening velocity and impaired muscle force. Regular physical exercise can mitigate these effects, but the impact of high-velocity resistance training (HVRT) on the F-V relationship of older individuals remains poorly understood (1). The goal of the present investigation was to assess whether HVRT can improve the F-V profile of different samples of older adults and evaluate the influence of different baseline F-V profiles on training responses and functional capacity.

METHODS: Middle-aged (n=14, 48±5 yrs) and older adults with (n=15, 69±7 yrs) and without (n=7, 76±8 yrs) mobility limitations were included in this study. The participants F-V profiles were determined both before and after a 12-wk HVRT program (3x/wk, 40-60% 1RM) in the leg press exercise using incremental loads ranging between 30-90% 1RM and a linear position transducer. The resultant F-V data points were fitted using linear regressions to estimate the maximal isometric force (F0), maximal unloaded velocity (V0), maximum power (Pmax), as well as the force (Fopt) and velocity (Vopt) at Pmax. Functional capacity was measured using the maximal gait speed (MGS) test. Timepoint x group repeated measures ANOVAs, t-tests, and linear regression models were used for statistical analyses.

RESULTS: All three groups improved Pmax, F0, and Fopt ($p<0.05$), whereas V0 and Vopt remained unchanged. Notwithstanding this, an inspection of the individual F-V curves revealed two major patterns in response to training: an increase in both V0 and F0 or an increase in F0 without changes in V0. A moderate negative correlation ($r=-0.63$, $p<0.001$) was observed between V0 at pre-training and change in V0, suggesting that the slower participants at baseline achieved greater

gains as compared to the faster individuals. This was also supported by comparisons between groups created based on V0 tertiles, which confirmed greater gains in V0 (11±9% vs. -1±10%; p=0.001) in the lowest V0 tertile. In this group, greater gains in V0 also correlated with changes in MGS (r=0.69, p=0.01).

CONCLUSION: Our results show that HVRT improves maximal force and power output in middle-aged and older adults. On average, the power gains were achieved through an increase in force without a concomitant increase in velocity. However, follow-up analyses of individual F-V profiles showed that the training-induced changes in V0 were contingent upon baseline V0 levels, with originally velocity-deficient subjects showing the largest gains (2). Hence, it can be concluded that HVRT improved power output through improvements in F0 in all subjects and gains in V0 in originally velocity-deficient subjects only. In the latter, improving V0 also seemed to influence the transfer of these improvements to functional capacity.

EFFECTS OF SPATIALLY EXPLORATIVE COGNITIVE-MOTOR TRAINING INTERVENTIONS IN NURSING HOME RESIDENTS ON LIFE SPACE MOBILITY AND SPATIAL ORIENTATION

FRICKE, M.1, MUEHLBAUER, T.2, JANSEN, C.P.3,4, SCHWENK, M.3,5, GRAMANN, K.1, WOLLESEN, B.1,6

<1> TECHNICAL UNIVERSITY OF BERLIN; <2> UNIVERSITY OF DUISBURG-ESSEN; <3> HEIDELBERG UNIVERSITY; <4> ROBERT-BOSCH-KRANKENHAUS STUTTGART; <5> UNIVERSITY OF KONSTANZ; <6> UNIVERSITY OF HAMBURG

INTRODUCTION: Due to multimorbidity, some older persons need to be hospitalized in nursing homes and consequently encounter an unfamiliar environment. Spatial abilities, including orientation in and navigation through the environment, are known to deteriorate with age, especially for unknown locations. This leads to difficulties in exploring the facilities and their surroundings, which often reduces the experienced radius to ones own room and the way to the dining hall, thus also limiting the physical and social interaction possibilities (Schrempft et al., 2019). Since cognitive-motor training counteracting the decline of spatial orientation abilities has been rarely implemented for nursing home residents a three-armed RCT was conducted in 18 German nursing homes.

METHODS: In each nursing home, one of three different intervention approaches were delivered to participating residents for 12 weeks, twice a week for 45 min each: the PROfit basic group performed functional strength, balance, flexibility, and walking exercises always at the same location, whereas the PROfit plus group changed the location three times while performing similar exercises as the PROfit basic group. The PROfit orientation group received environment-related spatial orientation tasks in addition to the relocation. Physical and cognitive functioning (especially spatial orientation) as well as psychological measures were assessed in all study groups at baseline, post-test (after 12 weeks) and follow-up (after 24 weeks). To capture spatial orientation abilities the sequence of landmarks from the residents room to a relevant everyday life location in the immediate vicinity of the facility (radius 300m) was assessed using photos (landmark sequence task). In addition, the caregivers rated the frequency, radius and independence with which the environment was visited in everyday life by applying the Nursing Home Life Space-Diameter (NHLSD).

RESULTS: N=438 nursing home residents (85.5 ± 8.9 years, 74,7 % female) were included in the PROfit project. Since data collection is expected to be completed by May 2023, preliminary data of a subgroup of the sample is currently available. n=115 participants (living in 4 different nursing homes) received either the PROfit basic or the PROfit plus intervention. Analyses of the NHLSD showed a significantly enlarged life space after the PROfit basic intervention (p= .017), but not for PROfit plus. Comparing pre-and post-training data, a positive trend was also discerned for the landmark sequence task in both groups, but no significant increase.

CONCLUSION: The preliminary data partly indicate positive effects with regard to life space and spatial orientation. If the current trend is confirmed for the overall sample, the most effective training should be implemented widely in nursing homes.

CAN WE PREDICT MAXIMAL HEART RATE IN OLDER ADULTS?

BOULAY, P.1, GHACHEM, A.1, POIRIER, P.2, SIGAL, R.J.3,4, KENNY, G.P.4

1UNIVERSITY OF SHERBROOKE, SHERBROOKE, CANADA. 2LAVAL UNIVERSITY, QUÉBEC, CANADA. 3UNIVERSITY OF CALGARY, CALGARY, CANADA. 4UNIVERSITY OF OTTAWA, OTTAWA, CANADA.

INTRODUCTION: Maximal heart rate (HRmax) is commonly used in exercise physiology to define exercise intensity and as a criterion for achieving maximal exertion. Since direct measurement of HRmax is not always practical, prediction equations were developed. However, validation of equations employing a large sample size of older adults is lacking. To the best of our knowledge, no study to date has used SuperLearner (SL) modeling combining base machine-learning algorithms to predict HRmax (pHRmax) using simple physical and physiological inputs. Our study aimed to validate and compare the accuracy of commonly used equations and a SL model to pHRmax in older men and women.

METHODS: Data from 1390 consecutive cardiorespiratory fitness test in older adults using a metabolic cart (MCD Medgraphics, MGC Diagnostics) were analyzed. All tests were done on cycle ergometer (Corival, Lode). To be considered

maximal, all tests had to be fatigue limited and verified with objective measures of conventional maximal exercise criteria (e.g. a plateau in rate of O2 uptake, plateau in HRmax, respiratory exchange ratio >1.1) [1]. A total of 1208 men (62.7%) and women with an average age 61.6±7.3 years meeting these criteria and were included in the analyses. Measured HRmax was compared to pHRmax using the following equations: Fox, Astrand, Tanaka, Gelish and Gulati [1] and a SL model. Pearson correlation and performance indicators such as R2, root mean squared error (RMSE) and Lin's Concordance Correlation Coefficient (CCC) were performed to assess correlation and compare accuracy between measured and pHRmax, while Bland and Altman analyses were used to assess agreement between measured and pHRmax.

RESULTS: Aerobic capacity was higher (33.7±9 vs 27.3±8.2 mlO2.min-1.kg-1; p<0.01) but no difference was observed for HRmax (156.1±14.7 vs 157±13.7 beats per minute (bpm)) in men and women, respectively. All pHRmax-derived equations were positively associated with measured HRmax (0.41 CONCLUSION: Our findings suggest that currently available equations and even a SL model show insufficient accuracy to pHRmax in older adults. Consequently, the use of predictive equations to estimate the level of physical exertion or intensity of exercise in older adults may be inaccurate and requires further investigation.

FIFTEEN YEARS OF NOCTURNAL HEART RATE VARIABILITY, A CASE STUDY OF A FOUR-TIME OLYMPIAN

HYNYNEN, E., VESTERINEN, V., NUMMELA, A.

FINNISH INSTITUTE OF HIGH PERFORMANCE SPORT KIHU

INTRODUCTION: Heart rate (HR) and heart rate variability (HRV) measurements are used in monitoring athlete's recovery status [1]. Aging is known to decrease, and good aerobic fitness to increase HRV [2], but what happens to HRV of an endurance athlete during a career of four Olympic Games?

METHODS: Subject of this case study was an elite-level race walker (main event 50 km), who recorded his nocturnal RR-intervals (RRI) regularly during his career to monitor his recovery status. RRI recordings were started when going to bed to sleep and stopped after waking up in the morning. RRI recordings were analyzed by using Firstbeat Sports software (ver. 4.7.3.1) and retrospectively studied on yearly basis. Recordings that had less than four hours of clean data were omitted, and 4 242 recordings were included in this study. Lactate thresholds and maximal oxygen uptake (VO2max) were analyzed 2-4 times per year on an indoor track in 7×1000 m test at gradually increasing speed. Annual average HR and HRV indices as well as annual average lactate thresholds and VO2max were further studied in relation to age of the athlete (23-37 yrs). A repeated measures ANOVA with Tukey post-hoc tests were used to detect changes between the years and Pearson's correlation coefficients were used to detect relationships between variables.

RESULTS: Annual average nocturnal HR was found to stay relatively stable, increasing from 51 ± 3 bpm at the age of 23 yrs to 53 ± 2 bpm ($p<0.001$) at the age of 37 yrs. Much greater changes were seen in HRV indices over the years, as RMSSD declined from 97 ± 10 ms at the age of 23 yrs to 55 ± 6 ms ($p<0.001$) at the age of 37 yrs. Age was found to correlate negatively with annual average RMSSD ($r=-0.962$, $p<0.001$) and positively with HR ($r=0.592$, $p=0.020$). No correlation was found between age and VO2max ($r=-0.029$, $p=0.920$), but age was found to correlate positively with the speed at first lactate threshold ($r=0.661$, $p=0.007$). Speed at first lactate threshold correlated also negatively with RMSSD ($r=-0.609$, $p=0.016$).

CONCLUSION: As shown previously in cross-sectional studies [1], gradual decline in nocturnal HRV was also found in present elite athlete between the age of 23 and 37 suggesting reduced vagal activity. Physical fitness has been found to positively correlate with HRV, but in the studied elite athlete, improvement in the speed at the first lactate threshold suggests improvement in physical fitness over the 15 years of follow-up. It seems that for monitoring athlete´s recovery status [2] the reference values of individual HRV indices should be updated on yearly basis.

IS-SH05 Virtual Reality Technologies for understanding and improving sports performance

USING VIRTUAL REALITY TO MEASURE PERCEPTION-ACTION DEFICITS POST-CONCUSSION

CRAIG, C.

QUEENS UNIVERSITY BELFAST

To successfully intercept a moving object, a tight link has to exist between what a person sees (perception) and what a person does in response (action). Previous research has shown how concussion, or mild traumatic brain injury, can disrupt perception-action coupling leading to improper motor execution and increased risk of future injury. This talk will show how Virtual Reality can significantly improve on current concussion tests and protocols by providing dynamic decision-making tasks that can detect significant deficits in sensorimotor control 3 to 5 days post-concussion in players who have

passed standard concussion protocols. In short, this talk will demonstrate how Virtual Reality presents a robust, low-cost, portable solution for capturing deficits in sports performance.

VR FOR VISUO-MOTOR SKILL LEARNING: REVOLUTION OR NEVERLUTION?

VINE, S.
UNIVERSITY OF EXETER

irtual Reality technology and techniques are increasingly being adopted for motor skill learning in sports environments. VR is proposed to provide a way of learning and practising motor skills that overcomes some of the limitations of traditional methods of learning and practise. For example, VR has been proposed to provide practical benefits, such as flexibility and manoeuvrability; pedagogical benefits such as measurement and variety; perceptual motor benefits such as re-enactment of complex sensori-motor couplings, and generation of perceptually complex environments; and psychological benefits such as exposure to distracting and complex environments that often surround the performance of the motor skills. Research is beginning to emerge in support of some of these features...but this research is in its infancy and limited in several ways. First the breadth and depth of the evidence base provided in this space is growing, but is still limited in its ability to enable firm conclusions about the efficacy of VR to be drawn. Second, the research in this space is still relatively rudimentary in terms of research design, data analysis, and theoretical basis. This means that there is very little consensus among researchers about how VR technology and techniques should be assessed; and as such uncertainty among the sporting community about whether VR is a revolution that they want to join, or a short term trend that will not stand the test of time.

This presentation will briefly describe the existing literature relating to applications of VR for visuomotor skill learning, and explore weaknesses or gaps in the literature that need resolving. Suggestions will be made for ways in which the research area should grow, in order to develop a sound evidence base for the assessment of sports VR. An evidence base that will enable clear recommendations to be made to coaches, teams, and governing bodies of sport.

The findings will be discussed in the context of sports skill learning, but also in terms of other features of sports skill training, such as coaching, tactics, or post-match analysis.

VR FOR TRAINING PERCEPTUAL-MOTOR SKILLS OF BOXERS AND RELAY RUNNERS FOR PARIS 2024 OLYMPIC GAMES

KULPA, R.
UNIVERSITY RENNES 2

The revolution in digital technologies, and in particular Virtual Reality, in the field of sport has opened up new perspectives for the creation of new modalities for analysing and training the skills underlying performance. Virtual Reality allows for the standardisation, control and variation (even beyond real conditions) of stimuli while simultaneously quantifying performance. This provides the opportunity to offer specific training sessions, complementary to traditional training ones. In addition, in order to continuously improve, athletes need to train more and more but they reach their physical limits. Virtual Reality can create new training modalities that allow them to continue training while minimising the risk of injury (for example, due to the repetition of high-intensity work in races for a 4x100m relay or due to the impacts of defensive training in boxing). It may also be relevant for injured athletes who cannot physically practise their discipline but need to continue to train perceptually and cognitively by confronting field situations.

In this talk, we will describe how Virtual Reality is effectively implemented in the French Boxing and Athletics federations to train athletes anticipation skills in their preparation for the Paris 2024 Olympic Games. In the 4x100m relay, the teams performance depends in part on the athletes ability to synchronise their movements and therefore initiate their race at the right moment, before the partner arrives in the relay transmission zone, despite the pressure exerted by the opponents. The Virtual Reality training protocols are therefore designed to train each athlete to initiate his or her race at the right moment, with a tireless and always available avatar, based on the motion capture of real sprinters, whose race characteristics can be configured in terms of speed, lane, curvature, gender, etc. In boxing, the federation wants to improve boxers anticipation skills in defensive situations without making them undergo repetitive blows that could injure them, which is impossible in real training. Virtual Reality training protocols allow boxers to focus on the appropriate information on the opponent, which should enable them to anticipate attacks and adopt the relevant parry. In this talk we will therefore show how these different challenges can be addressed in the REVEA project through the deployment of an interdisciplinary research programme.

HISTAMINE ORCHESTRATES AN EXERCISE-INDUCED INFLAMMATORY RESPONSE IN THE HUMAN SKELETAL MUSCLE MICROENVIRONMENT DRIVING GLYCOGEN RESYNTHESIS

VAN DER STEDE, T.1,2, VAN DE LOOCK, A.1, HANSEN, C.2, TAMARIZ-ELLEMANN, A.2, TURIEL, G.3, DE BOCK, K.3, VANDESOMPELE, J.4, RICHTER, E.2, GLIEMANN, L.2, HELLSTEN, Y.2, DERAVE, W.1

<1> GHENT UNIVERSITY, <2> COPENHAGEN UNIVERSITY, <3> ETH ZURICH, <4> GHENT UNIVERSITY

INTRODUCTION: Histamine, a signalling molecule working via specific histamine receptors, promotes the sustained elevation of muscle blood flow after exercise (1). This hyperperfusion could relate to facilitating training adaptations, since we showed that administration of histamine receptor antagonists blunts exercise-induced adaptations in aerobic capacity, insulin sensitivity and microvascular function (1). To further understand the role of histamine during exercise, we determined which cell types within skeletal muscle express histamine receptors. Next, we performed exercise interventions to measure the secretion of histamine from working muscle, and to assess how this contributes to the acute exercise response, with a focus on muscle glycogen metabolism.

METHODS: A single cell RNA-seq dataset was explored to assess expression of histamine receptors in the cell types present in human skeletal muscle. In two independent cohorts each, we measured histamine secretion during one-leg knee extensor exercise into the interstitial space (vastus lateralis microdialysis, n=12M and n=7M) and circulation (femoral arterial-venous difference, n=20F and n=7M). To study the histamine receptor-mediated exercise response, healthy, young volunteers (12M, 2F) performed a high-intensity interval cycling session on 3 different days: placebo, histamine H1-receptor antagonist (540mg fexofenadine) or histamine H2-receptor antagonist (40mg famotidine). Muscle biopsies of the vastus lateralis were collected before exercise, and after 0 and 3 hours of recovery. Muscle glycogen was determined, combined with whole muscle transcriptomics (Gene Set Enrichment Analysis) and phospho-regulation analysis of the insulin signalling pathway by Western blot. Differences over time or between conditions were analysed using a linear mixed model approach.

RESULTS: Histamine H1-receptors were expressed on macrophages and endothelial cells, whereas H2-receptors were expressed on macrophages, neutrophils and smooth muscle cells. In both cohorts, histamine levels into the muscle interstitial space increased during exercise (3.4 and 9.6-fold), but not in the circulation. During the 3h recovery period, glycogen was significantly resynthesized in placebo (+125 mmol/kg, $p<0.001$) and H2-receptor antagonist (+67 mmol/kg, $p=0.041$), but not with H1-receptor antagonist (+25 mmol/kg, $p=0.625$; different from placebo, $p=0.019$). Western blot and transcriptome results indicate that not muscle insulin signalling, but inflammatory signals were blunted, mainly in H1-receptor blockade.

CONCLUSION: We uncover a cell type-specific expression of histamine receptors in human skeletal muscle. The selective release of histamine into the muscle interstitial space indicates an exercise-induced histamine signalling. Collectively, these data suggest a histamine-mediated intercellular crosstalk in the skeletal muscle microenvironment, contributing to the metabolic recovery, such as glycogen resynthesis, after acute exercise.

AMINO ACID TRANSPORTERS IN HUMAN SKELETAL MUSCLE ARE CHANGED WITH REGULAR STRENGTH TRAINING IN YOUNG AND OLD ADULTS

LANDER, E.

NORWEGIAN SCHOOL OF SPORT SCIENCE

INTRODUCTION: Increased intracellular amino acid availability in skeletal muscle facilitates muscle protein synthesis (MPS). Postprandial availability is dependent on transmembrane bound amino acid transporters (AAT) transporting amino acids from the blood into the cell and dysfunctional AATs may cause attenuated anabolic muscle response to feeding, termed anabolic resistance, in elderly and in sedentary adults. This study aimed to investigate possible differences in AATs in young and older adults and whether regular strength training changes AAT levels and their regulators.

METHODS: Healthy young (n=24, 20-40 yrs) and old (n=24, 70-80 yrs) adults completed a 12-week whole-body strength training intervention (3/week). Before and after the intervention, an acute study with strength exercise and protein intake was performed, lean leg mass (LLM) was measured by dual-energy X-ray absorptiometry, and strength was tested in leg press as one repetition maximum (1RM). Muscle biopsies were obtained from m. vastus lateralis and fractionated and analyzed with western blots in the cytosolic (C), membrane (M) and nuclear (N) fractions for the AATs: LAT1(C), CD98(C,M,N), SLC38A9(M), LAT3(C); and the regulators eIF2α (C,M,N) and ATF4(C,N). Data was analyzed using a two-way ANOVA, and a Pearson R for correlations.

RESULTS: Training increased LLM by ~1kg in both groups ($p<0.001$). 1RM leg press increased more in the young than old (78±32 kg vs 50±20 kg, $p<0.001$). Before training, the old had higher SLC38A9-M levels ($p<0.05$) and lower LAT1-C levels ($p<0.05$) than young. Training increased CD98-N by 59±97% in the young ($p<0.01$), ATF4-N by 191±362% in the old ($p<0.05$) and eIF2α-N levels in both groups (young: 41±67%, old:65±101%, $p<0.05$) which led to higher eIF2α-N levels in the old than young ($p<0.05$). In untrained state, exercise decreased eIF2α-N ($p<0.01$) and LAT1-C ($p<0.01$) in the young

group. In trained state, exercise increased eIF2α-N ($p<0.01$) and decreased ATF4-N ($p<0.05$) in the old and both groups decreased ATF4-C ($p<0.05$). The protein levels of LAT3-C did not change, and no differences were found between the groups in relative changes for any protein. After training and in relative changes, SLC38A9-M correlated with eIF2α-M ($r=0.57$, $p<0.05$) in the young and with LAT3-C ($r=0.64$, $p<0.05$) in the old. In relative changes, LAT1-C further correlated with ATF4-C in the old ($r=-0.61$, $p<0.05$) after training, and ATF4-N correlated with eIF2α-C ($r=0.76$, $p<0.001$) in the young and with eIF2α-N in both groups (young: $r=0.73$, old: $r=0.77$, $p<0.001$).

CONCLUSION: Strength training increased muscle mass and strength which were accompanied by increased eIF2α-N for both groups, ATF4-N in old and CD98-N in young. The differences between young and old adults in SLC38A9-M and LAT1-C was abolished after the training, but a difference between the groups in eIF2α-N levels emerged after the training. The observed changes in AATs and regulators may influence training adaptations, and regulation of amino acid uptake

INGESTION OF AN ANTI-LIPOLYTIC DRUG ALTERS WHOLE-BODY SUBSTRATE UTILISATION DURING BRISK WALKING EXERCISE IN OBESE INDIVIDUALS, BUT DOES NOT ALTER MUSCLE DIACYLGLYCEROL AND CERAMIDE CONCENTRATIONS

BARRETT, J.S.1, BENNETT, S.2, FORTIS, H.O.1, CUTHBERTSON, D.J.3, OWENS, D.J.1, STRAUSS, J.A.1, WAGENMAKERS, A.J.M.1, SHEPHERD, S.O.1

LIVERPOOL JOHN MOORES UNIVERSITY <1>, TEXAS A&M UNIVERSITY <2>, UNIVERSITY OF LIVERPOOL <3>

INTRODUCTION: Exercise increases turnover of the skeletal muscle lipid pool and enhances storage of fatty acids as intramuscular triglycerides (IMTG) in healthy individuals. In contrast, obese individuals have lower rates of IMTG turnover, even during exercise, leading to the accumulation of diacylglycerols (DAGs) and ceramides (Cer) and the development of insulin resistance. Ingestion of an anti-lipolytic drug prior to exercise reduces plasma free fatty acid (FFA) concentrations and increases IMTG utilisation during exercise. The aim of the current study was to investigate whether suppression of plasma FFA concentrations during and in the hours following exercise leads to alterations in muscle Cer and DAG species in obese individuals.

METHODS: Ten obese (BMI >30 kg.m-2) sedentary individuals performed two separate 45-minute treadmill walking trials at 45% VO2max followed by 3 hours recovery. For one trial, participants ingested the anti-lipolytic drug, Acipimox (250 mg), 1-hour before and again immediately post-exercise. During the other trial nothing was ingested. Muscle samples were obtained at baseline, immediately post-exercise, and after 3-hours of recovery. Serial blood samples were taken throughout. Muscle samples were analysed by liquid chromatography tandem mass spectrometry for lipids.

RESULTS: Plasma FFA concentrations were lower in the Acipimox trial compared to control ($P<0.05$). Mean carbohydrate oxidation rates during exercise were greater in the Acipimox trial (1.21 ± 0.46 g.min-1) compared to the control trial (1.01 ± 0.38 g.min-1; $P=0.002$) and mean fat oxidation rates were significantly greater in the control trial (0.38 ± 0.10 g.min-1) compared to the Acipimox trial (0.28 ± 0.07 g.min-1; $P=0.009$). Total DAG or ceramide concentrations did not change during exercise or during recovery ($P=0.34$). No changes in Cer species were observed in either condition. The concentration of glucosylceramides 24:0 and 24:1 were both increased immediately following exercise in both conditions. Total lactosylceramide (LacCer) concentrations were significantly increased by exercise, as were the species LacCer 20:0, LacCer 22:0, and LacCer 24:0. However, no differences between conditions were apparent. Notably, exercise-induced increases in concentration of LacCer species appeared to be sustained following 3 hours of recovery.

CONCLUSION: Here, ingestion of an anti-lipolytic drug suppressed plasma FFA concentrations and altered whole-body substrate utilisation during 45 min of brisk walking in obese individuals. Although no changes in Cer were seen during exercise and recovery in either condition, we speculate that both the rate of synthesis and degradation of Cer and GluCer is being increased by exercise, resulting in greater formation of LacCer. Ongoing transmission electron microscopy analysis to measure subcellular lipid droplet content and morphology will reveal further insight on the effect of Acipimox on turnover of the IMTG pool during exercise.

DICLOFENAC DIFFERENTIALLY REGULATES MUSCLE MRNA EXPRESSION LINKED TO LIPID METABOLISM DURING RESISTANCE EXERCISE TRAINING IN HEALTHY VOLUNTEERS, BUT HAS NO IMPACT ON IMCL CONTENT

CHIVAKA, P.K., MALLINSON, J.E., TAYLOR, T., CONSTANTIN, D., CONSTANTIN-TEODOSIU, D., SIMPSON, E.J., GREENHAFF, P.L.

THE UNIVERSITY OF NOTTINGHAM

INTRODUCTION: Diclofenac is a non-steroidal anti-inflammatory drug reported to be used off-label to enhance athletic training adaptation [1]. In vitro evidence shows that diclofenac binds to, and activates, peroxisome proliferator-activated receptor gamma (PPAR-gamma). This, alongside the activation of PPAR-gamma Coactivator 1a (encoded by PPARGC1A), upregulates the expression of mRNAs associated with lipid metabolism [2]. The impact of diclofenac administration on in vivo lipid metabolism remains largely unexplored. This study investigated the impact of diclofenac administration on intramyocellular lipid (IMCL) content and the expression levels of muscle mRNAs in healthy volunteers over the course of a 12-week resistance exercise training intervention.

METHODS: Following informed consent and screening, 17 young, healthy, exercise-trained males were allocated to Diclofenac (75mg diclofenac sodium daily; n=9; 25 ± 4 years; 24.8 ± 2.7 kg/m²) or Placebo (n=8; 24 ± 5 years; 23.5 ± 2.5 kg/m²) groups. Groups were matched for isometric leg strength, age, and BMI at baseline. All participants performed 5x30 sets of maximal isokinetic (90 degrees/s) knee extensions, with the non-dominant leg, 3x weekly over 12 weeks. Fasted state Vastus Lateralis muscle biopsies were obtained before and after 1, 7, 28, and 84 days' training, and were analysed for IMCL content (histochemical determination) and the expression levels of 93 targeted muscle mRNAs using

RT-PCR and microfluidic gene cards [3]. Two-way repeated measures ANOVA was used to identify differences in IMCL content between the groups across time points, and Ingenuity Pathway Analysis (IPA) was used to identify gene networks and metabolic predictions related to lipid metabolism.

RESULTS: IMCL content was no different between the groups at baseline (7.4 ± 3.8% Placebo vs. 6.9 ± 2.6% Diclofenac, mean ± SD), and no time/treatment interactions with resistance exercise training were observed (eta²p=0.07). IPA predicted robust activation of cellular events regulating lipid metabolism in both groups over the initial 28 days of training. However, by day 84, this previously predicted activation was no longer evident in the Placebo group. In keeping with this, PPARGC1A mRNA expression at day 84 in the Placebo group was less compared to baseline ($p<0.001$), but conversely greater than baseline in the Diclofenac group ($p<0.001$).

CONCLUSION: Diclofenac administration differentially altered the mRNA expression of genes regulating muscle lipid metabolism following 84 days of resistance exercise training in humans. Furthermore, the increased expression of PPARGC1A mRNA in the Diclofenac group implicates a mechanism by which diclofenac binds to PPAR-gamma in vivo and activates lipid metabolism cellular events. These responses were not associated with changes in IMCL content.

PHYSICAL CONDITION AND ACTN3 RS1815739 AND TFAM RS1937 POLYMORPHISMS IN SPANISH CHILDREN. THE UP&DOWN STUDY

LIM, T., RUBIO-ZARAPUZ, A., SILVA, A.J., GARCIA-GARCIA, L., MARCOS, A., GÓMEZ-GALLEGO, F., VEIGA, O., CASTRO-PIÑERO, J., SANTIAGO, C., YVERT, T.

UNIVERSIDAD EUROPEA DE MADRID

INTRODUCTION: Physical condition (muscular strength and power, cardiorespiratory fitness) plays an important role in the health status of individuals and may be genetically determined from childhood. Some genes have been associated with these traits. These include the gene coding for sarcomeric protein alpha actinin 3, ACTN3 gene, and the gene coding for the mitochondrial transcription factor, TFAM gene. Genetic polymorphisms associated with strength and power (ACTN3 rs1815739) and endurance (TFAM rs1937) have been described in both genes in the adult population. The information available regarding the relation between physical condition and genetics in paediatric population is still scarce and poorly understood.

For this reason, the aim of this study was to determine the potential interactions between the ACTN3 rs1815739 and TFAM rs1937 polymorphisms, and the physical condition in Spanish children from the UP&DOWN study (1).

METHODS: 539 children (271 girls) aged between 5 and 12 years (mean=8.25±1.68 years) from the UP&DOWN study were analysed. The following variables were measured in order to collect data of upper- and lower-limb strength, aerobic capacity and motor ability: handgrip strength dynamometry, standing long jump test, 20m track shuttle run, 4x10m shuttle run test. ACTN3 rs1815739 and TFAM rs1937 polymorphisms genotypes were analyzed using Applied Biosystems™ Taqman probe (ID: C_590093_1_ and C_8975662_10 ID, respectively). Physical condition variables were compared to the ACTN3 and TFAM polymorphisms by ANOVA and T test for parametric and Kruskal-Wallis for non-parametric variables.

RESULTS: For ACTN3 rs1815739 analyses, children with TT genotype presented significantly higher results at the standing long jump test than the children with CC and TC genotypes (110.19±19.87 cm vs. 105.22±18.69 cm, p=0.037, Cohen's d= 0.254). We also found significant differences for the TFAM rs1937 genotypes: children with GG genotype showed lower results for 20m track shuttle run compared with children with CG and CC genotypes (2.51±1.46 vs. 3.55±1.42, respectively; p=0.017; Cohen´s d= 0.71).

CONCLUSION: Although calculated effect size was low, the results obtained for ACTN3 rs1815739 polymorphism are contrary to literature, the C allele being generally related to muscular strength and power in adult population. ACTN3 is a protein specific to type II fibers, thus, the differences in muscle fibers proportions and maturation state in children compared to adults, could explain our results. In the case of TFAM rs1937 polymorphism, our results (presenting moderate-high effect size) are consistent with previous knowledge in adult population: C allele is associated with long distance exercise performance and better aerobic capacity. Therefore, it seems genetic factor could play an important role in cardiorespiratory fitness from childhood through the regulation of mitochondrial transcription.

EFFECTS OF A 7-DAY HIIT SHOCK MICROCYCLE WITH OR WITHOUT ADDITIONAL LOW-INTENSITY TRAINING ON MAXIMAL OXYGEN UPTAKE AND TIME TRIAL PERFORMANCE – RANDOMIZED CONTROLLED TRIAL

STREPP, T.1, BLUMKAITIS, J.1, HALLER, N.1,2, STÖGGL, T.1,3

1.UNIVERSITY OF SALZBURG, 2. UNIVERSITY OF MAINZ, 3. RED BULL ATHLETE PERFORMANCE CENTER SALZBURG

INTRODUCTION: High-intensity interval training (HIIT) shock microcycle (SM, i.e., multiple HIIT sessions in a short period of time) appears effective for improving endurance parameters. However, whether HIIT-SM leads to improvements in maximal oxygen uptake (VO2max) [1, 2], or not [3, 4], is controversial. Further, the effect of additional low-intensity training (LIT) during HIIT-SM on VO2max and the transfer of lab-based effects on time trial (TT) performance has not yet been investigated. Therefore, the aim of this study was to assess the effect of HIIT-SM with or without additional LIT on VO2max and TT performance.

METHODS: Thirty trained endurance athletes (7 women, 23 men) performed a sub-maximal incremental and maximal ramp test running on a treadmill to determine VO2max and maximal heart rate (HRmax) (T1). Participants were then randomly assigned to one of three groups: 1) HIIT-SM=10 running-based HIIT sessions, i.e., 5x4 min at 90-95% HRmax, over 7 days 2) HIIT-SM+LIT=equal to HSM with additional 30-min of LIT after each HIIT 3) CON=regular training. Physiological exercise testing was repeated on 3 days (T2), 7 days (T3), and 14 days (T4) after the intervention. A 5-km TT (5kmTT) was performed 3-4 days before T1 and 10-11 days after the intervention. Between-group differences were analyzed using a linear model (ANCOVA) with pre-test values as the covariate, group as the fixed factor, and each post-test as the dependent variable. Independence of the covariate was tested with ANOVA. Effect sizes (ES) are expressed as partial eta-squared. Within-group comparisons between pre-test and each post-test were done using paired sample T-test. Level of significance was set at $P<0.05$.

RESULTS: VO2max at T1 was 60.3±6.9, 60.3±5.2 and 59.5±2.6 mL/min/kg for HIIT-SM, HIIT-SM+LIT and CON, respectively, with no differences between groups (P=0.92 ES=0.01). No between-group differences in VO2max at T2 (+0.8%, -0.4%, -1.1%; P=0.67; ES=0.03), T3 (+1.6%, +2.0%, -4.6%; P=0.053; ES=0.20), and T4 (+1.5%, +1.9%, -2.6%; P=0.30; ES=0.09) could be observed. There were no within-group changes in VO2max for all three groups. Mean pre-test 5kmTT was 19:31±2:27, 19:14±1:36, and 18:58±1:26 min, respectively, with no difference between groups (P=0.82; ES=0.02). No between-group differences in 5kmTT at the post-test (-2.5%, -2.1%, +0.0%; P=0.14; ES=0.14) could be observed. Within-group improvements were revealed for HIIT-SM (P=0.046) and HIIT-SM+LIT (P=0.03).

CONCLUSION: Both 7-day HIIT-SM with or without additional LIT had no effect on VO2max in endurance trained athletes. No effects in 5kmTT could be observed, despite within-group improvements in both intervention groups. HIIT-SM with or without additional LIT may influence other endurance performance-related parameters.

LACTATE THRESHOLD IN ELITE RACE WALKERS – DESCRIPTIVE STUDY OF DEVELOPMENT RATES AND ASSOCIATED TRAINING

WALTER, N., FLECKENSTEIN, D.

INSTITUTE OF APPLIED TRAINING SCIENCE LEIPZIG

INTRODUCTION: The lactate threshold (LT) is one of the most important physiological factors in race walking. However, research concerning the development of this factor and the associated training in elite race walkers is limited [1]. Therefore, the aim of this descriptive study was to determine the development of LT for different training phases of elite race walkers and to describe the realised training.

METHODS: The study is based on retrospective data from 1992 to 2018, collected at the Institute of Applied Training Science in Leipzig. The athletes included in the study were members of the German national team and competed at international level. To determine the LT, athletes completed a step test on the treadmill (4-6x 3000 m, increments: 0.2 m/s, rest duration: 60 s). LT was defined as the velocity where the lactate-velocity-curve crossed 3.0 mmol/l lactate. Furthermore, training data were collected with a standardized diary and processed in an Access database. Male athletes with an age of at least 22 years and a baseline LT of at least 3.6 m/s were included. The development of LT and the average training were investigated for three training phases (P1: preparation phase 1 from Nov/Dec to Jan/Feb, P2: preparation phase 2 from Jan/Feb to Mar/Apr, P3: competition phase from Mar/Apr to June/July). All data are given as mean ± standard deviation.

RESULTS: 33 training phases of 14 athletes with a baseline LT of 3.85 ± 0.12 m/s, an age of 27.2 ± 3.0 years and a duration of 7.4 ± 1.8 weeks were selected for P1. The development of LT within P1 is 0.06 ± 0.10 m/s. The average training includes a training volume of 131.1 ± 43.2 km/week (walking and running), 8.6 ± 1.6 sessions/week (including strength and general endurance training) and an active training time of 12.1 ± 3.4 h/week. The average proportion of training volume near and above the LT (including competitions) is 17.3 ± 14.4 %. Regarding P2, 23 training phases of 9 athletes with a baseline LT of 3.83 ± 0.11 m/s, an age of 27.0 ± 3.0 years and a duration of 9.6 ± 1.4 weeks were analysed. LT increases by 0.04 ± 0.09

m/s. Training consists of 159.5 ± 36.5 km/week, 9.4 ± 1.5 sessions/week, 12.9 ± 2.8 h/week and a proportion of intensity training of 24.8 ± 17.0 %. Finally, 23 training phases of 11 athletes with a baseline LT of 3.92 ± 0.10 m/s, an age of 25.3 ± 1.7 years and a duration of 16.6 ± 2.3 weeks were selected for P3. LT development is 0.04 ± 0.12 m/s. Training includes 122.7 ± 32.4 km/week, 8.1 ± 1.1 sessions/week, 10.5 ± 2.8 h/week and intense walking of 18.9 ± 15.5 %.

CONCLUSION: The mean changes of LT seems small, but individual ranges of -0.17 to 0.31 m/s have to be considered. This study offers coaches a reference for the development of the LT and the associated training in elite race walkers. Further studies should investigate the statistical relation between changes of LT and different training parameters as well as the baseline LT.

THE EFFECT OF A SLEEP HYGIENE INTERVENTION ON COGNITIVE PERFORMANCE IN A 24H ULTRA-MARATHON RACE

BENCHETRIT, S.1, CORBETT, J.1, SHEPHERD, A.1, NEUPERT, E.1, MUDGE, H.2, DAWES, C.1, MACKINTOSH, K.3, MCNARRY, A.3, COSTELLO, J.1

1. UNIVERSITY OF PORTSMOUTH, 2. UNIVERSITY OF SOUTHAMPTON, 3. SWANSEA UNIVERSITY

INTRODUCTION: Ultra-marathons, endurance running events exceeding the 42.2 km distance of a traditional marathon, are increasing in popularity. Of concern, they often involve at least one night of sleep deprivation, which has been demonstrated to impair cognitive performance, particularly reaction time and executive function1. This study aimed to determine if a sleep intervention, implemented in the week prior to a 24h ultra-marathon, would reduce the impairment in cognitive performance after the race.

METHODS: Using a randomised controlled parallel-group design, 16 athletes (14 males, 2 females; mean±SD: age 45±7 years; height 1.77±0.05 m; mass 76.7±11.2 kg) undertook the ContiThunderRun, a continuous 24h race around a 10km loop. Sleep duration and efficiency was recorded at baseline (3-4 weeks prior to the race) and pre-race (7-days prior) using wrist-worn accelerometers (GENEActiv) with validated raw acceleration thresholds. The sleep intervention (INT) group received an online sleep hygiene seminar, aimed at improving the quality of sleep by promoting specific pre-bed behaviours2. The comparison group (COM) were instructed to sleep as they normally would pre-race. After familiarisation, Two Choice Reaction Time (2CRT) and response inhibition (Stroop task) were assessed pre- and post-race. Data were analysed using a repeated measures ANOVA and significance was accepted at $P<0.05$.

RESULTS: Due to drop-out, 14 participants were included in the final analyses [7 INT, 7 COM group; 2 females, 12 males; mean distance covered 123±35 km]. There were no significant effects of the sleep hygiene intervention nor any difference between the baseline and pre-race weeks for sleep duration [mean±SD, 394±22 vs 385±59 min, p=0.59] and efficacy [mean±SD, 89±4 vs 88±5 %, p=0.35]. Similarly, there was no main effect for intervention or intervention*time interaction (all $p > 0.05$) on any aspect of cognitive performance. However, there was a significant deterioration in cognitive performance post-race, with reaction time increasing [462±54 vs 520±108 ms; p=0.02] throughput (number of correct responses per min) reducing in the 2CRT task [124.5±15.4 vs 112.1±20.1; $p<0.01$] and the interference score in the Stroop task reducing [19.9±11.0 vs 15.1±6.2; p=0.02].

CONCLUSION: This study demonstrated that cognitive performance was impaired post-race; however there was no evidence that these effects were ameliorated by the intervention, which had no impact on either sleep duration or efficacy. The lack of effect may be, in part, explained by a summer heatwave (~40oC in London) coinciding with the week preceding the race (i.e. during the intervention), which could have impacted the effectiveness of the intervention. Further research investigating the impact of pre-race sleep strategies on cognitive performance during ultra-marathons is therefore required.

EFFECTS OF NEUROMUSCULAR ELECTRICAL STIMULATION ON WINGATE TEST AND BLOOD LACTATE ACCUMULATION

TAKEDA, R.1, NOJIMA, H.1, NISHIKAWA, T.1,2, OKUDAIRA, M.1, UEDA, S.3, HIRONO, T.1, WATANABE, K.1

1. CHUKYO UNIVERSITY, TOYOTA, JAPAN. 2. GRADUATE SCHOOL OF HEALTH AND SPORT SCIENCES, CHUKYO UNIVERSITY, TOYOTA, JAPAN. 3. SUGIYAMA JOGAKUEN UNIVERSITY, NAGOYA, JAPAN.

INTRODUCTION: It is well-known that sprint interval training (SIT) can improve aerobic and anaerobic exercise performance [1] and these improvements were associated with changes in lactate kinetics by SIT [2]. Because subtetanic neuromuscular electrical stimulation (NMES) with voluntary exercise (VOLES) does not increase fatigue despite promoting blood lactate accumulation [3], it may be an excellent approach for effective SIT. Elucidating how VOLES affects blood lactate accumulation after sprint training is essential to identify a purposeful application of NMES to SIT. Thus, we hypothesized that NMES with voluntary exercise could maintain 30-sec "all-out" exercise, i.e., Wingate test performance but augment blood lactate accumulation.

METHODS: Fifteen healthy young males (mean ± standard deviation, age: 23 ± 4 yrs, body mass index: 22.0 ± 2.1 kg/m2) volunteered for two trials on a separate day (randomized crossover study). After a 1-min resting baseline, participants performed a 3-min intervention: VOLES (NMES with free-weight cycling) or voluntary cycling alone, which matched oxygen uptake with VOLES (VOL, 43.6 ± 8.0 W). Then, they performed the Wingate test with 30-min free-weight cycling recovery.

The blood lactate concentration ([La]b) was assessed at the end of resting and intervention, and recovery at 1, 3, 5, 10, 20, and 30 min. The paired t-test was used to assess the performance of the Wingate test as well as effect sizes expressed as Cohen's d, and two-way analysis of variance was used to evaluate the [La]b between condition (VOLES vs. VOL) and time (resting vs. intervention vs. recovery) as well as effect sizes expressed as partial eta-squared. Bonferroni-corrected post-hoc procedures were used when applicable. A P-value of < 0.05 was considered significant.

RESULTS: [La]b during intervention was significantly higher in VOLES than in VOL (2.2 ± 0.5 vs. 1.6 ± 0.3 mmol/L, P=0.011, effect size = 0.402). The increase in [La]b after the Wingate test was maintained for longer in VOLES than in VOL at 10- and 20-min recovery (10-min, 14.0 ± 2.1 vs. 13.0 ± 1.5 mmol/L; 20-min, 10.6 ± 2.1 vs. 9.1 ± 1.9 mmol/L. P=0.014 and 0.023, effect size = 0.380 and 0.339, respectively). Based on the Wingate test, performance was similar between VOLES vs. VOL: peak power (686 ± 127 vs. 691 ± 125 W, P=0.184, effect size = 0.040), mean power (529 ± 81 vs. 534 ± 83 W, P=0.201, effect size = 0.061), and the rate of decline (35.6 ± 13.5 vs. 37.4 ± 11.3%, P=0.989, effect size = 0.145).

CONCLUSION: NMES with voluntary exercise did not impair Wingate test performance but sustained blood lactate accumulation for longer than with voluntary exercise alone during recovery. These results set the stage for future research on developing a new strategy for sprint interval training programs that promote more potent physiological stimuli without reducing exercise intensity by employing NMES.

IS-MH01 The IOC Consensus Statement of Relative Energy Deficiency in Sports (REDs) - 2023 update

ADVANCES IN THE FIELD OF REDS SCIENCE

KOEHLER, K.

TECHNICAL UNIVERSITY OF MUNICH

The causal role of low energy availability (LEA) in the aetiology and pathophysiology of REDs is well-established. However, most of the underlying data on the effects of LEA on endocrine and physiological outcomes stem from laboratory experiments involving strict manipulation of dietary energy intake and exercise expenditure. While these seminal studies have contributed immensely to our understanding of human energetics in the context of exercise, they focused largely on outcomes related female reproduction and bone health, were conducted in predominantly sedentary populations, and involved only short-term (<1 week) manipulations of diet and exercise.

However, with the inclusion of additional physiological and psychological outcomes as well as other populations into the REDs model, there has been growing body of laboratory and field studies investigating the effects of LEA on numerous other functions and outcomes related to health and performance. These include, but are not limited to, growth and adaptation, inflammation, substrate storage and utilisation, gastrointestinal issues and haematological aspects as well as potential sex- and age-related differences in the response to LEA, including thresholds for tolerable LEA doses. With growing evidence from observational and intervention studies, a clearer picture has emerged on the time course of physiological and psychological maladaptations in response to LEA, which can range from days to weeks (acute) to months to years (prolonged).

Furthermore, there is also growing evidence that not only LEA but also the pathway to LEA, i.e., whether it is achieved by dietary restriction, increased exercise, or a combination of both, may module a variety of physiological and psychological outcomes. The latter is particular relevant in light of the shared pathways between REDs and overreaching and overtraining syndrome (OTS), which require particular diagnostic attention.

Beyond energy availability, recent studies involving the deliberate manipulation of both energy and macronutrient availability have also highlighted the potentially amplifying role of low carbohydrate availability on specific physiological outcomes, such as bone health, inflammation and iron homeostasis.

THE NEW REDS CONCEPTUAL AND PHYSIOLOGICAL MODELS FOR HEALTH AND PERFORMANCE

BURKE, L.

AUSTRALIAN CATHOLIC UNIVERSITY

The current evolution of REDs encompasses the principle that although the accommodation of acute and mild LEA is to some extent, normal and advantageous, in some scenarios and individuals, it disrupts health and performance. The new REDs health and performance conceptual models demonstrate the range of body systems for which there is theoretical, empirical and/or clinical evidence of impairments that manifest in different ways. Undoubtedly, these outcomes occur over different timeframes, and with different levels of severity and significance to the individual athlete due to myriad moderating factors. The concept of the LEA threshold (i.e. 30 kcal/kg FFM/d), below which health problems occurred, was

based on elegant but short-term laboratory studies which investigated step-wise changes in EA and perturbation of hormones involved in the female reproductive system. Although this concept was always intended as a guide rather than a diagnostic end-point, more recent information gleaned from real-life clinical observations, as well as theoretical constructs around the frailty of a single, universal threshold, have identified large differences in the EA level apparently associated with health and performance concerns between individuals and between different body systems. Therefore, although EA calculations may inform research interventions or observations, there is danger in setting quantitative definitions of absolute concerns. While the conceptual models provide a simple education message for athletes, coaches and clinicians, the development of a more complex physiological model for the interaction of LEA each body system is encouraged. This should be undertaken with a "systems biology mindset" to enable a more nuanced assessment of the individual athlete and whether their specific exposure to LEA and the presence of secondary moderators (e.g. genetics, training characteristics, other nutritional issues, medication) is likely to be positive, neutral or negative in regard to functional outcomes. The evolution of the science and practice of REDs requires an interdisciplinary field of study, that can integrate complex biological interactions to understand real-life outcomes.

PREVENTION AND TREATMENT OF REDS

MELIN, A.

SPORTS SCIENCE

It is undeniable that severe and/or prolonged low energy availability (LEA) and REDs are common among both female and male athletes at different performance levels and may result in serious health (e.g. eating disorders and premature osteoporosis) and performance (e.g. injuries) consequences. Therefore, there is an emerging need to prevent the development of LEA and REDs.

This lecture targeting the athletes' entourage such as sport organisations, coaches and sport medicine clinicians will focus on the IOC recommendations regarding primary and secondary prevention strategies of REDs as well as treatment.

LEA is the underlying etiological factor of REDs, and primary prevention focusing on modifying risk factors for LEA within the sport environment is the best way to preserve health and improve performance among athletes. Primary prevention strategies should target athletes as well as their support team and focus on education of the importance of adequate energy and nutrient availability to ensure optimal health and performance. Furthermore, the educational programs should aim to improve e.g. self-esteem, and acceptance of physical changes related to adolescence, and reduce risk factors, especially de-emphasising the importance of a low body mass and leanness, particularly in young and sub-elite athletes.

Secondary prevention involves identification of REDs symptoms, using early treatment initiatives, prior to development of clinical diagnoses. Secondary prevention therefore includes screening and management of asymptomatic or symptomatic symptoms, including the new REDs Clinical Assessment Tool (CAT2) three-step approach. Self-reported screening instruments, individual health interviews, and objective assessment of REDs markers may be useful in this prevention phase.

The objective of clinical treatment (tertiary prevention) is to promote rehabilitation and to limit long-term, severe health and performance consequences of REDs. Before commencing a treatment program, accurate diagnosis is essential to tailor the treatment to the clinical presentation. Intervention at an early stage in the clinical presentation is desirable to minimise severity of health outcomes of REDs and expedite recovery. The cornerstone of therapy is to treat the underlying cause: LEA. Reversing the LEA can be achieved by decreasing energy output, increasing energy intake, or both in concert. A multidisciplinary treatment team is often required including clinicians specialising in sport medicine, sport dietetics, psychiatry/psychology, exercise physiology, endocrinology and gynaecology.

OP-MH06 Obesity

EFFECTS OF HIGH INTENSITY INTERVAL TRAINING AND MODERATE INTENSITY CONTINUOUS TRAINING ON CARDIAC FUNCTION IN OBESE YOUNG WOMEN

LOPES, W.A., RECK, H.B., LOCATELLI, J.C., SIMÕES, C.F., DE OLIVEIRA, G.H., MENDES, V.H.S., COSTA, C.E., OKAWA, R.T. P.

STATE UNIVERSITY OF MARINGA

INTRODUCTION: Obesity is an independent risk factor for cardiovascular diseases [1]. Both high intensity interval training (HIIT) and moderate intensity continuous training (MICT) have been shown to be equally effective for reducing whole-body fat mass in obese individuals [2]. However, the acute and chronic effects of HIIT and MICT on cardiac function have not yet been properly investigated [3]. Therefore, the aim of this study was to investigate the acute and chronic effects of HIIT and MICT on cardiac function in young obese women.

METHODS: Forty obese women completed this two-phase randomized controlled trial. In the first phase (acute protocol), 15 individuals performed a single bout of HIIT (4x4-min at 85-95% of maximal heart rate (HRmax)), MICT (41-min at 65-75% of HRmax), and control condition (CO). Data were collected at baseline and five (t5) and 35 (t35) minutes after each condition. In the second phase (chronic protocol), 25 individuals completed an eight-week HIIT or MICT protocol, being assessed at

baseline and after the exercise program. Anthropometric, body composition, cardiorespiratory fitness and cardiac function were evaluated.

RESULTS: Acute reductions in global longitudinal strain (GLS) (p=0.010; p=0.002), LV ejection fraction (LVEF) (p=0.017; p=0.010), LV end-diastolic volume (LVEDV) (p=0.001; p=0.048) were observed after HIIT at t5 in relation with baseline values and CO, respectively. GLS also reduced in comparison to MICT at t5 (p=0.013). E/A ratio decreased after HIIT in comparison to baseline (p= 0.001; p=0.001), CO (p<0.001; p=0.001) and MICT (p=0.027; p=0.008) at t5 and t35, respectively. Chronically, HIIT and MICT increased GLS (p=0.016; p=0.023), LVEDV (p=0.005; p<0.001) and stroke volume (p<0.001; p<0.001), respectively. Only HIIT increased LVEF (p=0.012) after the 8-week exercise program.

CONCLUSION: HIIT induced an acute reduction in LV function five minutes after exercise that were almost fully restored 35 minutes after HIIT performance. Chronically, both HIIT and MICT elicited similar improvements in LV function, but only HIIT enhanced LVEF, an important marker of LV systolic function in young obese women.

SERUM METABOLOME ADAPTATIONS ASSOCIATED WITH MUSCULAR STRENGTH FOLLOWING 12 WEEKS OF HIGH-INTENSITY INTERVAL TRAINING IN OBESE OLDER ADULTS

YOUSSEF, L., BOURGIN, M., DURAND, S., APRAHAMIAN, F., LEFEVRE, D., MAIURI, M.C., MARCANGELLI, V., DULAC, M., HAJJ-BOUTROS, G., GAUDREAU, P., MORAIS, J.A., GOUSPILLOU, G., KROEMER, G.

UNIVERSITÉ REIMS CHAMPAGNE ARDENNE

Aubertin-Leheudre, M., Noirez, P.

INTRODUCTION: One of the major adverse health effects of aging is the loss of muscle strength. As a standard clinical measure, it has been proposed that handgrip strength may be a marker of frailty assessment. The loss of muscle strength becomes much faster than the loss of muscle mass in older individuals, resulting in a decline of muscle quality. In addition to that, age and body fat have been shown to be inversely associated with muscle strength and quality. Therefore, preventing fat gain and preserving lean mass in obese individuals becomes an important issue. High-intensity interval training (HIIT) has been shown as an effective intervention strategy for obese older individuals. Hence, revealing possible mechanisms underlying the changes of muscular strength parameters would be of interest. The aim of this study was to evaluate serum metabolome changes related to muscular strength parameters changes after 12 weeks of HIIT in obese older adults.

METHODS: Twenty-six participants performed HIIT, (67.73 ± 3.87 yrs) three times per week for 12 weeks. Serum metabolome profile as well as clinico-biological parameters were assessed before and after the 12-week intervention. Blood serum samples were subjected to multiple different liquid or gas phase chromatography methods coupled to mass spectrometry.

RESULTS: Among the 364 metabolites and ratio of metabolites identified, 21 metabolites changed significantly following the 12-week HIIT intervention. Out of these metabolites, acyl-alkyl-phosphatidylcholine (PCae) (22:1) delta changes, a metabolite of the fat metabolism, significantly correlated with handgrip strength ($r = 0.52$, $p < 0.01$) delta changes, as well as with handgrip strength relative to arms lean mass delta changes ($r = 0.54$, $p < 0.01$) in the HIIT group.

CONCLUSION: Metabolites of the fat metabolism could play an important role in preserving muscular strength. The metabolite PCae (22:1) could be considered as a metabolite of interest for muscular strength, and hence for a healthy aging. Future studies are needed to confirm our promising results, thus allowing the development of therapeutic interventions for preserving muscular strength, and hence contributing to a healthy aging.

LEFT VENTRICULAR AND HEMODYNAMIC ADAPTATIONS FOLLOWING TWO WORKLOAD-MATCHED HIGH-INTENSITY INTERVAL TRAINING PROGRAMS WITH DIFFERENT BOUT DURATION IN OBESE MEN

BOGDANIS, G.C.1, TSIRIGKAKIS, S.1,2, KOUTEDAKIS, Y.2, MOUGIOS, V.3, TSEKOURA, D.1, MASTORAKOS, G.1

1,2:NATIONAL & KAPODISTRIAN UNIVERSITY OF ATHENS, 3: UNIVERSITY OF THESSALY, ARISTOTLE UNIVERSITY OF THESSALONIKI

INTRODUCTION: High-intensity interval training (HIIT) is a time-saving training strategy that provides at least similar benefits, in terms of cardiometabolic risk reduction, with moderate-intensity continuous training in the general population [1]. However, studies examining the effectiveness of different HIIT formats on cardiovascular health in obese adults are rather limited. The present study compared the effects of two workload-matched HIIT programs with different bout duration (10 vs. 60 s) on cardiorespiratory fitness and left ventricular structure and function in obese men.

METHODS: Sixteen untrained obese men (aged 38.9 ± 7.3 y) were randomly assigned to either a HIIT10 group, i.e., 48 bouts of 10 s at 100% peak power output (PPO) interspersed with 75 s at 15% PPO, or HIIT60 group, i.e., 10 bouts of 60 s at 100% PPO interspersed with 75 s at 15% PPO. Participants performed eight weeks of supervised training (24 sessions) on an electronically braked cycle ergometer. Before and after the training intervention, peak oxygen uptake (VO2peak) was assessed by an incremental cycle ergometer test and lactate threshold was estimated from a 5-stage submaximal test. Plasma volume changes were calculated from hematocrit and hemoglobin values measured in venous blood collected at rest before the first and last training sessions. Resting left ventricular (LV) function was assessed pre- and post-training using two-dimensional and Doppler echocardiography.

RESULTS: Analysis of variance showed a main effect of time ($p < 0.05$) and no effect of group or interaction ($p > 0.05$) in the examined parameters. Resting systolic and diastolic blood pressure decreased by 2.8 mmHg (90%CI: -4.5 to -1.1 mmHg; $p = 0.009$) and by 2.1 mmHg (90%CI: -3.5 to -0.6 mmHg; $p = 0.019$), respectively. There was an increase in ejection fraction by 3.2% ± 1.3% ($p < 0.001$) from pre- to post-training. This was accompanied by an increase in LV end-diastolic volume by 7.9% (or 8.3 mL, 90%CI: 3.9 to 12.8 mL; $p = 0.003$), and a decrease of LV end-systolic volume by 4.8% (or -2.1 mL, 90%CI: -3.4 to -0.8 mL; $p = 0.007$). Resting stroke volume increased by 10.0 ± 7.4 mL (from 82.3 ± 14.7 to 92.2 ± 14.0 mL, $p < 0.001$). VO2peak increased by 10.9 ± 6.1% on week 4 and by 20.0 ± 7.2% on week 8 ($p < 0.001$). Lactate threshold increased from 55.6 ± 7.4% to 64.8 ± 7.3% VO2peak ($p < 0.001$). Plasma volume at rest remained unchanged after 8 weeks of training.

CONCLUSION: Both HIIT protocols were effective in improving cardiorespiratory fitness, blood pressure and left ventricular morphology and function at rest in untrained obese men. Since metabolic stress and perceptual responses are milder in HIIT of shorter bout duration [2], HIIT10 may be preferable to promote cardiorespiratory health in obese men.

EFFECTS OF TWO ISOENERGETIC HIGH INTENSITY INTERVAL TRAINING PROGRAMS (CYCLING VS RUNNING) ON FAT MASS LOSS AND GUT MICROBIOTA COMPOSITION IN MEN WITH OVERWEIGHT OR OBESITY.

COUVERT, A., GOUMY, L., MAILLARD, F., ESBRAT, A., LANCHAIS, K., SAUGRAIN, C., VERDIER, C., DORÉ, E., CHEVARIN, C., ADJTOUTAH, D., MOREL, C., MARTIN, V., LANCHA JUNIOR, A.H., BARNICH, N., CHASSAING, B.

UNIVERSITY OF CLERMONT AUVERGNE / CENTER OF RESOURCES, EXPERTISE AND PERFORMANCE IN SPORTS OF BELLERIVE SUR ALLIER / UNIVERSITY OF PARIS / UNIVERSITY OF SÃO PAULO

Rance, M., Boisseau, N.

INTRODUCTION: High-intensity interval training (HIIT) protocols decrease fat mass (FM) deposits, including abdominal and visceral FM. Recent studies performed by our team in rodent models (1,2) and in humans (3) suggest that HIIT could modulate the intestinal microbiota composition and this might contribute to FM loss. To date, FM loss and the possible association between FM reduction and intestinal microbiota composition changes have never been compared using different isoenergetic HIIT modalities, such as cycling and running. Therefore, the aim of this study was to assess these parameters before and after a 12-week cycling (HIIT-BIKE) or running (HIIT-RUN) HIIT program in men with overweight or obesity.

METHODS: Sixteen men (54±10 years; BMI: 30±2 kg/m²) were randomly assigned to the HIIT-BIKE (10 x 45s at 85% of the estimated HRmax, 90s active recovery) or HIIT-RUN (9 x 45s at 85% of the estimated HRmax, 90s active recovery) group (training 3 times per week, for 12 weeks). Dual-energy X-ray absorptiometry was used to measure whole-body, abdominal and visceral FM. Nutritional intake and physical activity level were established with self-report questionnaires. Gut microbiota composition was determined by 16S rRNA gene sequencing at baseline and after the 12-week HIIT program.

RESULTS: Energy intake and physical activity levels did not vary from the beginning to the end of the intervention in both groups. Overall, body weight, and total, abdominal and visceral FM decreased over time. When values were expressed as percentage change, no difference was observed for weight, total and visceral FM between groups. Conversely, abdominal FM loss was greater in the HIIT-RUN than HIIT-BIKE group (-16.1% vs -8.3%; $p < 0.05$). The alpha-diversity (Shannon index) of gut microbiota did not vary over time or between groups, but overall, the alpha-diversity variation was associated with abdominal FM change ($r = 0.74$; $p < 0.05$). The two HIIT programs did not induce specific intestinal microbiota alterations. However, the baseline microbiota profile and gut composition changes were correlated with total, abdominal and visceral FM losses.

CONCLUSION: Whatever the modality, HIIT is an efficient strategy to promote total, abdominal and visceral FM loss in men with overweight or obesity. The mechanisms underlying the higher abdominal FM reduction in the HIIT-RUN compared with the HIIT-BIKE group require additional investigations. No specific intestinal microbiota member changes was observed between groups, but the baseline intestinal microbiota composition and its variation during training were correlated with the FM reduction, reinforcing the possible link between these parameters.

VERY LOW-VOLUME INTERVAL TRAINING IMPROVES TELOMERE LENGTH IN OBESE METABOLIC SYNDROME PATIENTS

RELJIC, D., EKICI, A., HERRMANN, H.J., NEURATH, M.F., ZOPF, Y.

UNIVERSITY HOSPITAL ERLANGEN

INTRODUCTION: The metabolic syndrome (MetS) is a cluster of cardiometabolic disorders including excess abdominal fat storage, hypertension, hyperglycemia and dyslipidemia, which jointly pose an increased risk for serious sequelae. Recently, it has been reported that MetS is also linked with an accelerated shortening of telomeres [1]. Telomeres are specific DNA-protein structures located at the end of chromosomes and play a key role in the protection and stabilization of genomes. Telomeres typically shorten with age at each cell division and thus, telomere length (TL) is considered a major biomarker of biological age. Apart from the normal aging process, there are several other factors that have been identified to promote telomere shortening, including diseases associated with chronic low-grade inflammation and oxidative stress like MetS [1]. On the contrary, life-style factors such as regular aerobic training have shown potential to preserve or even increase TL [2]. The aim of the present study was to explore whether very small amounts of exercise in form of low-volume interval training (LOW-HIIT) would have a beneficial impact on TL in in obese MetS patients.

METHODS: Obese individuals with clinical diagnosis of MetS were randomized into a 12 week LOW-HIIT program (2x/week, 5x1 min vigorous exercise intervals interspersed by 1 min recovery phases on cycle ergometers, 14 min total session duration including warm-up and cool-down) or a non-exercising control group (CON). Both groups received standard-care nutritional counseling to support weight loss. Pre- and post-intervention, patients received a comprehensive health examination including blood analysis, body composition measurement and cardiopulmonary exercise testing. TL was determined according to the quantitative PCR method producing a ratio of telomere amount and amount of a single gene copy (T/S-ratio) [3].

RESULTS: Ninety-one patients (52±13 yrs, BMI: 37.6±6.0) completed the intervention (LOW-HIIT: n=57; CON: n=34). Both groups similarly reduced body weight by ~3.3 kg. In the LOW-HIIT group, T/S-ratio increased significantly from 0.78±0.14 to 0.83±0.16 (p=0.002). Additionally, LOW-HIIT group patients experienced improvements in VO2max (+3.5 mL/kg/min, p<0.001), MetS severity score (–1.7, p<0.001) and self-reported quality of life (+11%, p<0.001). None of these outcomes improved in CON.

CONCLUSION: The results of this study indicate that even very low volumes of targeted exercise performed as LOW-HIIT may have a beneficial impact on TL in obese individuals with MetS. Given the similar amount of weight loss in LOW-HIIT and CON, the observed effects appear to be independent of body weight changes and underpin the well-established health benefits of exercise. Further research is required to investigate whether these results can also be transferred to other populations.

OP-AP18 Resistance Training Programs

EFFECTS OF TWO PERIODIZATION MODELS (LINEAR VS. NONLINEAR) ON MAXIMAL STRENGTH AND EXPLOSIVE STRENGTH PARAMETERS IN A GROUP OF YOUNG ADULT MALE VOLLEYBALL PLAYERS

MOUSSI, L., EL HAGE, R.

UNIVERSITY OF BALAMAND, FACULTY OF ARTS AND SCIENCES. DEPARTMENT OF PHYSICAL EDUCATION.

INTRODUCTION: The purpose of this study was to compare the effects of two models of periodization (linear and nonlinear) on maximal strength and explosive strength parameters in a group of young adult male volleyball players.

METHODS: This study included 30 players, between 18 and 23 years old. Stratified sampling was used to divide the athletes into all of the three groups, LIN (n=10), NLIN (n=10), and CON (n=10). All the tests were done using validated protocols. The intervention was carried for 6 weeks; each week included 2 sessions in the gym and 3 volleyball training sessions for the LIN and NLIN groups. The CON group did 5 volleyball trainings per week. The LIN group changed the training program every two weeks, the NLIN group had different intensity every session.

RESULTS: There were no significant differences in all the pre-intervention values among the three groups. As showed by the two-way repeated-measure ANOVA test, there were significant group x time interactions for most of the studied parameters. Also, significant pre-post changes were noted for most of the studied parameters in LIN and NLIN groups. In addition, there were significant differences among the three groups regarding percentage of variation of strength and explosive strength parameters.

CONCLUSION: In conclusion, a 6-week LIN or NLIN periodization program induces significant improvements in the maximal strength and explosive strength parameters of young adult male volleyball players. In addition, the NLIN program presented better results than the LIN in the best vertical jump, block jump, squat jump height and leg curl. In contrast, the

LIN presented better results compared to the NLIN in the 10m sprint. In conclusion, both periodization models (LIN and NLIN) are effective in enhancing maximal strength and explosive strength parameters in amateur volleyball players.

CLUSTER ANALYSIS SHOWS NO SIGNIFICANT VARIATION IN TRAINING VOLUME VARIABLES ACROSS HYPERTROPHIC ADAPTATIONS IN TRAINED INDIVIDUALS

DE SOUZA, E.1, WADHI, T.2, BARSUHN, A.1, SAVLA, R.1, UGRINOWITSCH, C.3

1-THE UNIVERSITY OF TAMPA, 2-AUCKLAND UNIVERSITY OF TECHNOLOGY, 3-UNIVERSITY OF SAO PAULO

INTRODUCTION: Resistance training (RT) volume and its impact on muscle size adaptations in resistance-trained individuals are of interest to the scientific community. Previous studies have overlooked important confounding variables, such as participants previous weekly sets number performed per muscle group (PSN), set differences between previous training volume and sets performed during the experimental period (Set-Diff), etc. We aimed to examine if RT volume variables explain muscle growth when individuals are clustered according to hypertrophic adaptations after an RT regimen.

METHODS: Data from 63 resistance-trained individuals (1RM: BM= 2.01□0.26;18 to 30 yrs) who volunteered for previous studies in our lab were analyzed in this project. After an 8-week RT program, a K-means cluster was performed to identify three responder clusters based on the absolute delta change in the sum of medial and distal muscle thickness points (□SMT) and DEXA region of interest for fat-free mass change (□ROI-FFM). Clusters were labeled as HIGH (N=9), MODERATE (N=31), and LOW (N=23) responders. PSN, Set-Diff, weekly sets performed during the study (SPS), total volume load (sets x repetitions times x load) [TVL], and volume load progressions between the first and second training block (□VL) were analyzed with a one-way ANOVA. A Tukey adjustment was implemented for multiple comparisons in the case of significant F values. The significance level was set at P<0.05. Results are expressed as mean and 95% confidence intervals.

RESULTS: □SMT was greater in HIGH when compared to MODERATE and LOW (p<0.05). MODERATE increased more □SMT than LOW (p<0.05), (HIGH: 2.14, 95%-CI: 1.715 to 2.565cm, MODERATE: 0.787, 95%-CI: 0.577 to 0.997cm, and LOW: 0.217, 95%-CI: 0.032 to 0.402cm. □ROI-FFM was higher in HIGH than MODERATE and LOW (p<0.05). MODERATE also increased more □ROI-FFM than LOW (p<0.05), (HIGH:2.722, 95%-CI: 2.178 to 3.267kg, MODERATE: 1.532, 95%-CI: 1.371to 1.693kg, and LOW: 0.147, 95%-CI: -0.043 to 0.338kg). RT volume variables did not differ between clusters (p>0.05): PSN-HIGH: 14.49, 95%-CI: 10.37 to 18.61 sets, MODERATE: 13.32, 95%-CI: 9.86 to 16.77 sets, and LOW: 13.97, 95%-CI: 10.88 to 17.06 sets; Set-Diff-HIGH: 3.73, 95%-CI: -1.311 to 8.778 sets, MODERATE: 5.168, 95%-CI: 1.97 to 8.365 sets, and LOW:4.026, 95%-CI: 0.864 to 7.187 sets; SPS-HIGH: 18.22, 95%-CI: 10.29 to 26.15 sets, MODERATE: 18.48, 95%-CI: 15.30 to 21.66 sets, and LOW: 18, 95%-CI: 15.53 to 20.47 sets; TVL- HIGH: 411560, 95%-CI: 302,757 to 520,3639kg, MODERATE: 544,855, 95%-CI: 444,610 to 645,099kg, and LOW: 562,230, 95%-CI: 466,187 to 658,273kg); □VL- HIGH: 30.521, 95%-CI: -3.882 to 64.932kg, MODERATE: 48.827, 95%-CI: 32.265 to 65.389kg, and LOW: 47.239, 95%-CI: 31.730 to 62.749

CONCLUSION: The present study corroborates Scarpelli et al (2020) and our previous findings (Aube et al.2020), as muscle growth was not affected by SPS and TVL. Intrinsic biological factors still determine the magnitude of RT-induced adaptations in trained individuals.

LOAD-VELOCITY PROFILE ADAPTATIONS IN THE TRAINED AND UNTRAINED LEG AFTER RESISTANCE EXERCISE PROTOCOLS DIFFERING IN SET CONFIGURATION- THE CROSS-EDUCATION PHENOMENON.

RIAL-VÁZQUEZ, J.1,2, FARIÑAS, J.1, RÚA-ALONSO, M.1,3, NINE, I.1, IGLESIAS-SOLER, E.1

1 PERFORMANCE AND HEALTH GROUP, UNIVERSITY OF A CORUNA 2 CENTRE FOR SPORT STUDIES, REY JUAN CARLOS UNIVERSITY, FUENLABRADA, 3 CIDESD

INTRODUCTION: Cross-education phenomenon is a neurological response to a unilateral strength training resulting in a strength gain in the contralateral untrained limb (1). Training parameters are determinant to modulate the strength transfer (2) and individualized load-velocity profiles (LV) are useful to evaluate that gains (3). The aim of this study was to compare the load-velocity changes in trained and untrained limb after two unilateral resistance training programs with equated total volume and work-to-rest ratio but differing in set configuration.

METHODS: 35 active subjects were recruited. After obtaining the individual LV profiles for unilateral knee extension (KE) exercise, subjects were divided in 3 groups: Traditional Training (TT), Cluster Training (CT) and Control (CON) group. Experimental groups completed 10 training sessions (5 weeks) consisting in unilateral KE exercise. Only dominant limb was exercised with the 10-repetition maximum (10RM) load. TT performed 4 sets of 8 reps with 3 min of rest between sets, whereas CT carried out 32 sets of 1 rep with 17.5 seconds of rest. From the LV profile we obtained: the velocity and load axis intercept (V0 and L0) and the area under de line (Aline=V0.L0/2). Additionally, from a load-power polynomic equation, we analyzed: changes in the estimated maximum power (Pmax), the percentage of 1RM where Pmax (%Pmax) occurs and the load associated to Pmax (LPmax).

RESULTS: Regarding the trained limb, higher values of L0 were recorded after training (p=0.009) without group×time interaction. No significant changes were observed for V0 and ALine. Greater values of Pmax were observed in posttest for TT (218.13W vs. 256.10W) (p=0.001) but not for CT nor CON. Similar values were recorded for %Pmax in posttest but higher values of LPmax were observed (p=0.001) without group×time interaction.

No changes were observed in L0 and ALine in posttest for the untrained limb. No changes in V0 were detected for CT and TT whereas lower values were registered in CON (p=0.010). A tendency towards higher V0 values in CT compared to TT in posttest (p=0.085) was detected. Pmax was increased in posttest (p=0.009) without group×time interaction. Similar values of %Pmax and LPmax were observed in posttest.

CONCLUSION: LV profile remained unchanged in the trained limb after intervention but sightly improvements in L0 and LPmax were observed independent of the group. TT intervention promoted an increase in Pmax whereas CT did not. LV profile remained unchanged in the untrained leg for the experimental groups but a tendency towards flatter slopes in the CON group reflect a loss of velocity in the posttest. Set configuration did not modulate the LV changes in the trained nor in the untrained leg. The LV profiles were not sensitive enough to reflect the effect of the cross-education phenomenon.

IN-SEASON AUTOREGULATION OF ONE WEEKLY STRENGTH TRAINING SESSION MAINTAINS PHYSICAL PERFORMANCE IN PROFESSIONAL MALE FOOTBALL PLAYERS

BYRKJEDAL, P.T.1, THUNSHELLE, A.2, SPENCER, M.1, LUTEBERGET, L.S.1,3, IVARSSON, A.1,4, VÅRVIK, F.T.1, LINDBERG, K.1, BJØRNSEN, T.1

1. UNIVERSITY OF AGDER, 2. IK START, 3. NORWEGIAN SCHOOL OF SPORT SCIENCES, 4. HALMSTAD UNIVERSITY

INTRODUCTION: While studies have tested different autoregulation methods within the competitive season (1), the use of typical monitoring tools such as GPS-tracking systems and external load performance data, seem to be unexplored. The aim of this study was therefore to compare the effects of autoregulating strength training volume based on an objective (external load match performance) versus a subjective (self-selected) method in professional male football players in-season.

METHODS: Sixteen players were randomly assigned to an external load regulated (EXL: n=7, 24.1±4.7 yrs, 181.4±5.1 cm, 76.6±7.1 kg) or a self-selected (SELF: n=9, 23.7±3.9 yrs, 185.0±6.9 cm, 77.4±8.4 kg) group and completed a 10-week in-season strength intervention period. The EXL-group regulated strength training volume based on their high intensity running (HIR: >19.8 km/h) distance from preceding football matches, and performed 3, 2 or 1 set of each exercise, based on thresholds of <421m, between and >687m, respectively. SELF-group was instructed to reflect on their subjective feeling and readiness to train, and select the number of sets based on their subjective rating of readiness. Physical performance (30-m sprint, countermovement jump, leg-strength) and body composition (DXA) were assessed pre- and post-intervention period.

RESULTS: No significant differences were observed between the groups at baseline. During the 10-week intervention period, both groups performed 1.1±0.1 bout of ~6 sets in leg extensor exercises and Man-Whitney U test revealed no group differences (p>0.05) in training volume (number of strength-training sessions, or number of sets in leg extensor exercises completed). No group differences were detected in physical performance and body composition measures post-intervention. Wilcox signed rank test showed that no significant pre- to post differences were evident in the physical performance measures for either group, or when analyzing all players as one group. For body composition, a statistically higher leg mass and legs lean mass was shown at post- compared to pre-test, for the EXL-group (0.4±0.4kg, p=0.031 and 0.4±0.3, p=0.034) and when analyzing all players as one group (0.3±0.6kg, p=0.039 and 0.2±0.6kg, p=0.024).

CONCLUSION: Our findings demonstrated that an objective autoregulation of strength training volume based on football match HIR distance did not differ from using a self-regulation based on their subjective readiness to train during a 10-week intervention period. This is likely explained by a low, and similar volume in the strength training undertaken. This study demonstrates that one-weekly in-season strength training session with ~6 sets of leg extensor exercises, applied by either an objective or subjective autoregulation method, can maintain professional football players physical performance during a competitive period.

WHEELCHAIR PARA-ATHLETES MAY BE PROTECTED FROM POOR BONE HEALTH BY THE DEGREE OF IMPACT IN THEIR SPORT

RISVANG, L.C.1, WEIJER, V.2, VAN DIJK, J.W.2, MOBERG, E.3, BOVIM, L.P.V.4, LILJEGREN, A.M.F.4, STRØM, V.1,5, RAASTAD, T.1, JONVIK, K.L.1

1NORWEGIAN SCHOOL OF SPORT SCIENCES, NORWAY, 2HAN UNIVERSITY OF APPLIED SCIENCES, THE NETHERLANDS, 3UNIVERSITY OF OSLO 4WESTERN NORWAY UNIVERSITY OF APPLIED SCIENCES 5SUNNAAS REHABILITATION HOSPITAL

INTRODUCTION: We have previously presented a higher prevalence of low bone mineral density (BMD; osteopenia, Z-score<-1.0) in the lumbar spine and hip in wheelchair-dependent (WC) para-athletes compared to their walking counterparts. Hence, WC non-athletes are assumed to be at an even higher risk of low BMD due to a lack of mechanical loading

from exercise. In this international multi-center study, we aimed to compare the BMD of the lumbar spine and hip between WC para-athletes and WC non-athletes.

METHODS: Lumbar spine, hip, and femoral neck BMD were measured by a dual-energy x-ray densitometry (DXA) scan. All participants filled in a background questionnaire on personal characteristics and training history. Explosive, rotational, and collision sports (WC rugby, tennis and basketball, and alpine sit-ski) were classified as high-impact sports (HIS), and static and one-dimensional sports (cross-country sit-ski, hand cycling, and others) were classified as low-impact sports (LIS). Data are presented as mean±SD. Where suitable, one-way ANOVA, two-sample t-tests, and Pearson correlation analyses were employed. Only valid DXA scans are utilized, as such, analysis n are provided where data are missing.

RESULTS: Of 57 WC users (17-56 yrs; 48% female), 31 were classified as HIS, 13 as LIS, and 13 as non-athletes based on the criteria of sport participation>2 yrs. The overall mean BMD Z-scores were -0.2±1.4 for the lumbar spine (n=45; 31% Z-score<-1.0), -1.3±1.2 for the hip (n=54; 56% Z-score<-1.0), and -1.2±1.4 for the femoral neck (n=49; 51% Z-score<-1.0).

HIS athletes had significantly higher lumbar spine Z-scores (0.5±1.3; n=21) compared to LIS athletes (-1.5±0.9, adjusted P<0.001; n=11) and tended to be higher than non-athletes (-0.3±1.3, adjusted P=0.07). Furthermore, HIS athletes showed a higher hip Z-score (-0.8±1.0; n=28) than LIS athletes (-2.1±1.2, adjusted P<0.01), but not higher than non-athletes (-1.5±0.8, adjusted P=0.11). No significant differences were found between LIS and non-athletes for both lumbar spine and hip Z-scores (both adjusted P>0.05). No group effects were found for the femoral neck (P>0.05).

Overall, lean mass was significantly associated with lumbar spine BMD Z-score (r=0.36, P=0.02), tended to correlate with the femoral neck Z-score (r=0.24, P=0.09), but did not correlate with the hip Z-score (P>0.05). Nor was there any association between any of the BMD Z-scores and years at the national team level or habitual weekly training hours (all P>0.05). Participants with congenital diagnosis (n=26; age: 33±12 yrs) had significantly lower lumbar spine Z-scores (-0.6±1.4) compared to those with acquired diagnosis (n=19; age: 31±10 yrs; 0.3 ±1.5, P=0.04).

CONCLUSION: This study shows that 31-56% of WC users present low BMD, depending on the site measured. The higher BMD seen in HIS athletes may indicate a positive effect of high-impact activities. Exercise programs for preventing and treating low BMD should therefore aim to include such activities achievable for WC users.

THERAPEUTIC BENEFITS OF ANKLE-FOOT PROSTHESES DURING DAILY ACTIVITIES: A SYSTEMATIC REVIEW

LATHOUWERS, E., DÍAZ, M.A., MARICOT, A., TASSIGNON, B., CHERELLE, C., CHERELLE, P., MEEUSEN, R., DE PAUW, K.

VRIJE UNIVERSITEIT BRUSSEL

INTRODUCTION: Enhancing the quality of life of people with a lower limb amputation is critical in prosthetic development and rehabilitation. Yet, no overview is available concerning the impact of passive, quasi-passive and active ankle-foot prostheses on quality of life. Therefore, the aim of this study was to systematically review the therapeutic benefits of performing daily activities with passive, quasi-passive and active ankle-foot prostheses in people with a lower limb amputation.

METHODS: We searched the Pubmed, Web of Science, Scopus and Pedro databases and backward citations until November 3, 2021. Only English-written randomised controlled trials, cross-sectional, cross-over and cohort studies were included when the population comprised individuals with a unilateral transfemoral or transtibial amputation, wearing passive, quasi-passive or active ankle-foot prostheses. The intervention and outcome measures had to include any aspect of quality of life assessed while performing daily activities. We synthesised the participants characteristics, type of prosthesis, intervention, outcome and main results and conducted a risk of bias assessment using the Cochrane risk of bias tool. This study is registered on PROSPERO, number CRD42021290189.

RESULTS: We identified 4281 records and included 34 studies in total. Results indicate that quasi-passive and active prostheses are favoured over passive prostheses in the short-term. None of the included studies investigated the long-term effects of the prostheses, and none of the studies compared active with quasi-passive prostheses. Among the included studies, quality of life has been evaluated in the short term using biomechanical (n = 26), physiological (n = 10), performance-related (n = 19) or subjective measures (n = 10). These measures were collected during level walking (n = 34), slope walking (n = 9), standing (n = 2), circuit walking (n = 1), stair climbing (n = 1), standardized clinical tests (n = 1) and rock climbing (n = 1). All studies had a moderate or high risk of bias.

CONCLUSION: Compared to passive ankle-foot prostheses, quasi-passive and active prostheses significantly enhance the quality of life during the performance of daily activities. Although short-term therapeutic benefits have been established favouring more advanced prostheses, outcome measures discrepancies prevail, and the long-term benefits remain unknown. Investigating these aspects within prosthetic evaluations may improve the quality of life of people with a lower limb amputation.

PREDICTION OF INJURIES, TRAUMAS AND MUSCULOSKELETAL PAIN IN ELITE PARALYMPIC VOLLEYBALL PLAYERS

GAWEL, E., ZWIERZCHOWSKA, A., GÓMEZ-RUANO, M.A., ZEBROWSKA, A.

AKADEMIA WYCHOWANIA FIZYCZNEGO IM. JERZEGO KUKUCZKI W KATOWICACH

INTRODUCTION: Volleyball is believed not to be a particularly dangerous sport. Nevertheless, the previous research conducted by the authors of the present study suggests that the rates of musculoskeletal pain and injuries among elite sitting volleyball players are high and may be intensified by compensatory mechanisms(Gaweł et al., 2021, Zwierzchowska et al. 2022abc). However, there is still lack of research that evaluated this issue in case of initial playing position i.e. sitting vs.

standing and type of impairment. Thus, the study aimed to identify the prevalence and location of injuries, traumas and musculoskeletal pain in Paralympic and Olympic volleyball players based on an impairment and initial playing position (sitting/standing) and to identify the predictors of the abovementioned variables using a classification and regression tree (CRT)

METHODS: 75 male and female(age=34.1±;11.1;BH=1.83±0.1;BM=82.3±15.2)elite Paralympic and Olympic volleyball players from 7 countries took part in the study. They were divided into SG1 of lateral amputee Paralympic players, SG2 of able-bodied Paralympic volleyball players and SG3 of able-bodied Olympic volleyball players. A direct-participatory observation method was used in the study including a modified injuries and traumas survey questionnaire from Zwierzchowska et al.(2020) and NMQ-7 questionnaire. The CRT analysis was used to predict which training-related (sitting/standing playing position) and body-related (lateral amputation/no amputation) variables better classified the risk of the prevalence of injuries and theirs effect on athlete's health and sports performance.

RESULTS: Both SG1 and SG3 were characterized by similar prevalence of musculoskeletal pain (60/62) and injuries (55/53), while the lowest prevalence was identified in SG2. Both humeral and knee joint were the most frequent locations of the musculoskeletal pain and/or injuries in all studied groups, excepting low back pain that occurred mostly in SG1 and SG3. In SG1 musculoskeletal pain and injuries located mostly in the upper limbs, what is in the contrary to SG3, in whom they occurred in lower segments of the body.For SG1 the CRT analysis showed 7 significant influencing factors on a five-stage tree, while in SG2 and SG3 9 significant factors were identified. Eighteen nodes were mainly established by injury – ankle(level 1), break in training for 2 weeks(level 2), surgical treatment after injury and injury during trainings(level 3), overload injuries(level 4), fraction and low back pain(level 5) in both studied groups, while in SG2 and SG3 additional influencing factors were identified including injury – fingers(level 2) , injury – elbow joint(level 3).

CONCLUSION: 1.Extrinsic compensatory mechanism (initial playing position - sitting/standing) may be a crucial variable for prediction of musculoskeletal pain, injuries and traumas in volleyball players.

2.Lower limb amputation seems to impact on the prevalence of musculoskeletal complaints.

3.Training volume may predict LBP.

VALIDATION AND CROSS-SECTIONAL EXPLORATION OF A TEST PROTOCOL TO MEASURE ANAEROBIC AND AEROBIC POWER IN WHEELCHAIR ATHLETES

JANSSEN, R.J.F., VEGTER, R.J.K., HOUDIJK, H., VAN DER WOUDE, L.H.V., DE GROOT, S.

1 UNIVERSITY OF GRONINGEN, UNIVERSITY MEDICAL CENTER GRONINGEN, CENTER FOR HUMAN MOVEMENT SCIENCES, THE NETHERLANDS

2 Peter Harrison Centre for Disability Sports, School of Sport, Exercise and Health Sciences, Loughborough University. 3 Center for Rehabilitation, University Medical Center Groningen, Groningen, The Netherlands; 4 Department of Human Movement Sciences, Faculty of Behavioural and Movement Sciences, VU University, Amsterdam, The Netherlands; 5 Amsterdam Rehabilitation Research Center Reade, Amsterdam, The Netherlands.

INTRODUCTION: Wheelchair athletes currently lack standardized wheelchair-specific tools for an objective monitoring of their anaerobic and aerobic power production. Therefore, the aim of this study was to evaluate the validity of an individualized and standardized test protocol to measure the wheelchair-specific anaerobic and aerobic capacity in any individual wheelchair athlete and to provide a cross-sectional exploration of their performance capacities.

METHODS: Wheelchair athletes from basketball, rugby, tennis, triathlon and track & field performed an isometric strength test, a 10 s sprint test, a 30 s Wingate anaerobic test (WAnT) and a 1 min stepwise aerobic graded exercise test (GXT) on an instrumented roller ergometer. Using previously developed regression equations [1], the measured isometric strength was used to estimate the WAnT result (R2 = 0.75) and set an individual WAnT resistance. The measured WAnT result was used to estimate the GXT result (R2 = 0.81) and scaled the individual GXT resistance steps. The WAnT was considered valid when peak rim velocity stayed below 3 m/s. The GXT was considered valid when two out of three criteria were met: respiratory exchange ratio ≥ 1.10, heart rate ≥ 95% of predicted heart rate and rate of perceived exertion ≥ 8.

RESULTS: The test battery was completed by 38 wheelchair athletes of different sport disciplines in their own sports wheelchair. The five strongest athletes turned out to be too strong for the isometric strength test on the ergometer. Consequently, their WAnT resistance was underestimated, giving them the highest peak rim velocities (between 2.8 and 3.0 m/s). Instead, the sprint test was feasible for every athlete and showed the best estimate of the WAnT (R2 = 0.85). The resistance settings for the GXT were valid for every athlete. Isometric strength ranged from 140 N (tennis player) to 445 N (track and field athlete). Anaerobic power ranged from 72 W (rugby player) to 251 W (track and field athlete). Aerobic power ranged from 53 W (rugby player) to 156 W (tennis player).

CONCLUSION: The WAnT resistance was accurately estimated from the isometric strength for most athletes but was not feasible for the stronger athletes. The sprint test outperformed the isometric test as an estimator for the WAnT resistance and can instead be used as estimator for the WAnT resistance. The WAnT scaled the protocol for the GXT accurate and led to valid tests. The wide range in isometric strength, anaerobic power and aerobic power showed that this test protocol can be used in a diverse group of wheelchair athletes. The wider use of this individualized and standardized test protocol will lead to a more uniform way of wheelchair-specific exercise capacity testing and improved comparability of different studies.

IMPACT OF USING A RACKET DURING WHEELCHAIR BADMINTON PROPULSION.

ILONA, A.

UNIVERSITÉ DE TOULON

INTRODUCTION: Wheelchair badminton is a recent sport, and its peculiarity lies in the use of a badminton racket (BR) during wheelchair propulsion. To our knowledge, this particularity has not been studied in the field of wheelchair badminton but more widely studied in the context of wheelchair tennis, a discipline close to wheelchair badminton in which we find the same peculiarity. Prior studies found that using a racket during wheelchair propulsion have a negative impact on the performance and efficiency of wheelchair propulsion and on the risk of injury to athletes [1-3]. In view of these studies, it would be interesting to see if the use of a BR induces similar changes. The objective of our study is therefore to compare wheelchair propulsion with and without a BR to understand its impact on the performance. We hypothesized that the athletes maximum velocity, mean acceleration and mean deceleration would decrease when using BR.

METHODS: 18 French wheelchair badminton experimented players (41.4±9.3 years; 64.9±11.1kg; 169.7±13.7cm) were recruited in our study. They performed a consecutive forward (FP) and backward propulsion (BP) test for 1 min on a 3m straight line on a badminton court with and without BR. The athletes used their own wheelchairs equipped with inertial measurement units (IMU) on the wheels. These tools allowed us to collect the kinematic data on all forward and backward propulsion passages. We compare the dominant hand with and without BR.

RESULTS: In FP, maximum velocity decreased significantly with the use of a BR (4.57 ± 0.69 m/s vs 4.68 ± 0.65 m/s). Similar results were obtained for the mean deceleration which significantly decreased while using a BR (10.19 ± 4.26 m/s2 vs 11.12 ± 4.49 m/s2). In the same way, similar results were found comparing results with and without a BR in BP: the maximum velocity was higher without the use of a BR (4.21 ± 0.54 m/s vs 4.08 ± 0.65 m/s) and it is the same for the mean deceleration (10.22 ± 4.15 m/s2 vs 9.52 ± 3.45 m/s2). In contrast, no significant differences were found for mean acceleration but it tends to decrease for both propulsion.

CONCLUSION: Our hypothesis was partially verified since the maximum velocity and the mean deceleration decreased with the use of the BR in FP and BP without a significant decrease in the mean acceleration. But it tends to decrease. Thus, BR does have an impact on athletes and especially their performance. Future studies should focus on the risk of injury induced using BR.

ASSESSING REAL-WORLD MOVEMENT WITH CONSUMER-GRADE WEARABLE SENSORS: MEASURING SEGMENT ORIENTATIONS AND MOVEMENT QUALITY

SWAIN, T.1, MCNARRY, M.1, MANZANO-CARRASCO, S.2, MACKINTOSH, K.1

[1] SWANSEA UNIVERSITY, [2] UNIVERSITY OF CASTILLA-LA MANCHA

INTRODUCTION: In recent years, there has been increasing interest in the quantity as well as the quality of human movement and its impact on health and wellbeing. However, the ability to assess movement quality in the real-world remains a major limiting factor beyond a controlled laboratory environment. Therefore, the purpose of this study was to investigate the ability of consumer-grade wearables to assess movement quality and to consider the optimal sensor location for such assessments.

METHODS: Twenty participants (28.2 ± 7.4 years; 14 males) performed three sets of 10 repetitions of squats, good mornings, push-ups, and chair dips in a stratified randomised order whilst wearing seven Polar Verity Sense sensors, positioned on the chest, wrists, thighs, and ankles. A sensor-fusion algorithm was subsequently applied to the raw data to obtain three-dimensional orientations (pitch, roll, and yaw). Following synchronisation, sensor performance was validated against the criterion measure (Vicon) by determining the root-mean-square error (RMSE) for the decoupled Euler parameters.

RESULTS: For the squat, dip, and good morning, the mean global RMSE (i.e. the mean RMSE of the pitch, roll and yaw) for the chest-worn sensor was 5.0-6.9°. The ankle sensors generated a mean global RMSE of 4.1° and 12.9° for the good

morning and the squat, respectively, with mean global RMSE > 27.6° for the dip and push-up. The thigh sensors were most accurate for the good morning (mean global RMSE = 7.5°), with the remaining movements generating a mean global RMSE > 15.3°. Irrespective of movement, the global RMSE for the wrist sensors was consistently higher than all other placements (mean global RMSE > 15.3°; U = 655; p = 0.004).

CONCLUSION: Consumer-grade devices could support real-world movement analysis through the measurement of segment orientations. Accuracies comparable to previous research were observed under static conditions and when measuring uniplanar motion. The most accurate location for the assessment of movement quality was the chest, with soft tissue artifact and the proximity to a joint likely reducing movement-specific measurement accuracies. The findings of this study demonstrate the plausibility of using accessible consumer-grade wearable sensors to determine segment orientations, particularly when measuring uniplanar movements. However, this study also emphasises the importance of sensor placement when assessing movement quality to mitigate measurement errors. Future research should consider the integration of multiple sensor placements and continue to investigate calibration and post-processing data techniques.

PARAMETERS INFLUENCING THE ACCURACY OF A WRIST-PHOTOPLETHYSMOGRAPHY HEART RATE MONITOR (POLAR UNITE) DURING EXERCISE

BOSQUET, L., PERUQUE-GAYOU, E., WOLFS, E., BRETONNEAU, Q.

UNIVERSITY OF POITIERS

INTRODUCTION: Heart rate (HR) at rest, during exercise and/or after exercise cessation is a key measure in the monitoring of athletes, whether it is used to control exercise intensity or to monitor physiological adaptations to training load. However, assessing HR with a gold-standard electrocardiographic (ECG) system is not accessible, and wearing a chest strap is not without problems, notably in terms of user acceptance. To overcome these limitations, manufacturers have extended the range of their technological solutions by developing devices that measure HR at the wrist using a photoplethysmographic signal. However, the accuracy of this technique can be influenced by the tightening of the wristband, the movement of arms or the kinetics of the signal (e.g. steady-state exercise vs on- and off-transients). To test these hypotheses, photoplethysmographic and ECG signals were compared.

METHODS: 30 participants (50% females) randomly performed two 13' sequences (3' rest, 5' submaximal-intensity exercise, 5' passive recovery), on a motorized treadmill and a bicycle ergometer. HR was measured concomitantly with a 10-lead ECG and two wrist-photoplethysmography monitors (Polar Unite) with different tightening (free vs imposed at the maximum tolerable).

RESULTS: The level of association (r) and the error of measurement (CV) of the Polar Unite vs the 10-lead ECG is affected by the tightening of the wristband (normal vs high; r=0.83 and 0.96, CV=16.1 and 8.1% for the treadmill, respectively; r=0.71 and 0.97, CV=20.3 and 6.2% for the bicycle, respectively), by the phase of the signal (transition vs steady-state; r=0.90 and 0.97, CV= 9.0 and 7.6% for the treadmill, respectively; r=0.93 and 0.99, CV=7.5 and 3.1% for the bicycle, respectively) and by the movement of arms (treadmill vs bicycle; r=0.90 and 0.93, CV=9.0 and 7.5% during the transition phase, respectively; r=0.97 and 0.99, CV=7.6 and 3.1% during the steady-state phase, respectively). As compared with ECG, the decrease in HR at the end of the exercise began almost always later with the tightened Unite (97% of cases). For Δ60 (i.e. the decrease in HR during the first minute following the end of the exercise), r=0.73 and CV=27.47% for the treadmill, and r=0.93 and CV=11.71% for the ergocycle. By starting the analysis as soon as the HR begins to decrease, r=0.67 and CV=27.45% for the treadmill and r=0.94 and CV=9.74% for the ergocycle.

CONCLUSION: The accuracy of HR measured with a wrist-photoplethysmography monitor is affected by the wristbands tightening and the signals phase. A high tightening is required when high accuracy is expected. If the aim is to assess the reactivation of the parasympathetic system during the recovery phase, starting the analysis as soon as the HR begins to decrease may be relevant, especially when the exercise is performed on ergocycle.

VALIDITY OF A WEARABLE SENSOR FOR STROKE DETECTION IN YOUTH TENNIS PLAYERS

CUI, Y., ZHOU, Y., JOZEF, B., SHEN, Y.

1. BEIJING SPORT UNIVERSITY ; 2. CATAPULT SPORTS

INTRODUCTION: The practice of athlete monitoring in tennis used to be done via notational analysis, so that coaches or analysts manually count the stroke and empirically estimate the load player may experience. The advancement of in micro-sensors and intelligent algorithms allow for the automatic and more tennis-specific quantification of the load, which enables the monitoring of multiple players in real-time. The aim of the study was to validate a commercially available trunk-mounted wearable sensor in detecting the strokes of different techniques in youth tennis player.

METHODS: Fifteen youth tennis male players (International Tennis Number: 3 to 8) were recruited in the study and wore a GNSS and IMU based wearable device (Catapult Vector S7) between the scapulae using specific harness to collect the data of each stroke. During the experiment, players were required to perform 30 strokes of the following stroke in sequence with an interval of rest: forehand stroke, backhand stroke, volley, smash, serve, and shadow swings. The device manufacturer has developed a prototype algorithm to classify the recorded stroke into one of the following category: Forehand, Backhand, Serve and Other stroke. The Kappa statistic was used to measure the consistency between detected strokes by the device and the actual strokes.

RESULTS: For strokes with presence of the ball, a total of 1391 correct strokes were identified, 187 incorrect stroke numbers were identified, and 843 incorrect stroke types were identified. While during for shadow swings, a total of 1216 correct

strokes were identified; 58 incorrect stroke numbers were identified, and 1049 incorrect stroke types were identified. Higher Kappa coefficients were shown for forehand and backhand strokes detection (0.919 & 0.910 for ball strokes; and 0.904 & 0.959 for shadow swings), followed by that of serves (0.533 and 0.361). The device turned out to have poor to fair agreement with the actual counts in volley and smash (0.104 & 0.390; and 0.066, 0.316).

CONCLUSION: The wearable device tennis stroke detection algorithm presented good results with excellent consistency in detecting forehand and backhand strokes. However, younger players may not produce the aspects of stroke strength and turn amplitude that met the inclusion criteria of the algorithm, so that the smash and serve showed a fair to moderate consistency. Moreover, as the turn amplitude of the volley and stroke strength are comparatively slighter, and youth players showed more variance during stroke execution, it is possible that few strokes could be correctly classified using a single sensor placed between scapulae. The device should be applied with caution to quantify player's stroke load and adding wrist-mounted sensors could potentially improve detection accuracy.

SMART SWIM GOGGLES WITH AR DISPLAY ACCURATELY AND RELIABLY MEASURE SWIM PERFORMANCE METRICS IN RECREATIONAL SWIMMERS

EISENHARDT, D.1, KITS, A.2, MADELEINE, P.1, SAMANI, A.1, CLARKE, D.2, KRISTIANSEN, M.1

AALBORG UNIVERSITY <1>, SIMON FRASER UNIVERSITY, CANADA <2>

INTRODUCTION: Swimmers commonly access performance metrics such as lap splits, distance and pacing information between work bouts while they rest. Recently, a new category of tracking devices for swimming was introduced with the FORM Smart Swim Goggles (FORM Goggles). The goggles have a built-in see-through display and are capable of tracking and displaying distance, time splits, stroke, and pace metrics in real time using machine learning and augmented reality through a heads-up display. The purpose of this study was to assess the validity and reliability of the FORM Goggles compared to video analysis for stroke type, length count, length time, stroke rate and stroke count in recreational swimmers and triathletes.

METHODS: Thirty-six participants performed mixed swimming intervals in a 25-meter pool across two identical 900-meter swim sessions performed at comparable intensities one week apart. Participants wore FORM Goggles during their swims, which detected the following five swim metrics: stroke type, length time, length count, stroke count and stroke rate. Four video cameras were positioned on the pool edges to capture ground-truth video footage, which was then manually labeled by three trained individuals. Mean (SD) differences between FORM Goggles and ground truth were calculated for the selected metrics for both sessions. Absolute Mean Difference and Mean Absolute Percentage Error were used to assess the differences of the FORM Goggles relative to ground truth. Test-retest reliability of the goggles were assessed using both relative and absolute reliability metrics.

RESULTS: Compared to video analysis, the FORM Goggles identified the correct stroke type at a rate of 99.7% (N = 2354 lengths, $p < 0.001$), length count accuracy of 99.8%, and mean differences (FORM Goggles – ground-truth) for length time: -0.10s (1.49); stroke count: -0.63 (1.82), and stroke rate: 0.19 strokes/min (3.23). The test-retest ICC values between the two test days were 0.793 for length time, 0.797 for stroke count, and 0.883 for stroke rate. Overall, for length time the residuals were within ±1.0s for 65.3% of total lengths, for stroke count within ±1 stroke for 62.6% of total lengths, and for stroke rate within ±2 strokes/min for 66.40% of total lengths.

CONCLUSION: The FORM Goggles were found valid and reliable for tracking of length time, length count, stroke count, stroke rate, and stroke type during freestyle, backstroke, and breaststroke swimming in recreational swimmers and triathletes when compared to video analysis. This opens perspectives for receiving real-time information on performance metrics during swimming.

OP-SH01 Mentoring and Coaching: Talent

APPROACHING THE COACH'S EYE – AN INTERVIEW STUDY ON EXPERT COACHES' BELIEFS AND EXPERIENCES REGARDING 'TALENT' AND PLAYER SELECTION IN TABLE TENNIS

KOOPMANN, T.1, FABER, I.1,2, LATH, F.1,3, LOFFING, F.4, SCHORER, J.1

1 CARL VON OSSIETZKY UNIVERSITY OLDENBURG, GERMANY 2 WINDESHEIM UNIVERSITY OF APPLIED SCIENCES, ZWOLLE, THE NETHERLANDS 3 INSTITUTE OF APPLIED SPORT SCIENCE, LEIPZIG 4 GERMAN SPORT UNIVERSITY COLOGNE

Athlete identification and development programs are crucial for the development of young 'talented' children into world-class athletes (e.g., De Bosscher et al., 2008). Particularly in early starting sports and those with highly limited resources, systems personified by coaches often select athletes into programs already at a young age, aiming to use resources efficiently on those athletes with the highest potential. For example, the German table tennis system starts selecting players to national player development programs at age 10. However, the coaches' decision-making processes in the context of player selection (often referred to as coach's eye; Lath et al., 2021) and their specific criteria used are widely unknown. To address this gap, we conducted in-depth semi-structured interviews with fifteen coaches (five female, ten male; age: 32-78 years, M = 55, SD = 12.96) with high expertise in the identification and development of young talented table tennis players (10-60 years of experience, M = 28.80, SD = 13.94 years). Analysis reveals that the concept of 'talent' and the

process of player selection in table tennis are highly complex phenomena. In the interviews (duration: 41-79 min, M = 54.67, SD = 9.75 min), three main areas of importance were identified: 1) coaches' general beliefs regarding 'talent', 2) coaches' specific selection criteria including individual as well as environmental aspects, and 3) the system's implementation of player selection processes. One main finding is that coaches see 'talent' as dependent on various surrounding factors including (relative) age, maturation as well as previous (practice) experience. To their understanding, all these factors must be incorporated into selection decisions. Furthermore, coaches appreciate the multidimensionality of 'talent' and include both individual (e.g., technical skills) and environmental criteria (e.g., parents' support) in their decision-making process. Also, our interviews revealed that selection decisions are usually not made by a single but by multiple coaches during group meetings. This suggests that group processes and dynamics may play an important role. In summary, our work helps to further unravel the high complexity of 'talent' and player selection (in table tennis). With that, we provide new insights and avenues for practitioners and researchers in athlete selection. Future research should further investigate the coach's eye including the relevance of both individual and environmental as well as surrounding factors within athlete selection contexts.

WHAT DOES IT TAKE TO MAKE THE TEAM ? ANALYZING THE TALENT IDENTIFICATION PROCESS IN COMPETITIVE ICE HOCKEY

LEMOYNE, J., BRUNELLE, J.F., HUARD PELLETIER, V., GLAUDE-ROY, J., TRUDEAU, F.

UNIVERSITE DU QUEBEC A TROIS-RIVIERES

INTRODUCTION: In ice hockey, off-season evaluation camps are crucial steps in the preparation and training of national teams. Traditionally, such camps allow for a look at the evolution of different components of athletic talent such as 1) physical fitness, 2) technical skills, 3) psychological aspects and 4) performance in a game context. However, little is known about the real contribution of these camps in the team selection process. The objective of this study is to take a look at a talent identification process by analyzing the contribution of each talent determinant in competitive hockey.

METHODS: A 2-yr prospective design was conducted among two cohorts of highly competitive adolescent players (initial n = 160, 50 % male, 14 years old; 50% female, 16 years old) based in the province of Quebec (Canada). Players were informed about the process and accepted to participate in the project. The selection process was developed over a series of three evaluation camps (Camp 1: 80 male-100 females; Camp 2: 45 males-45 females; Camp 3: n = 25 males-25 females). At each camp, measures included off-ice fitness tests, on-ice skating tests, psychological measures and game performance throughout the full hockey season. All data was used in the team selection process, which was based on two-phases (Phase 1: from 2 x 80 to 2 x 45 players; Phase 2: from 2 x 45 to 2 x 20 players), which led to two team selections. Descriptive statistics, and discriminant analyses (selected versus non-selected players at each phase) were performed. The selection process according to each variable was compared according to each team (gender).

RESULTS: In phase 1, descriptive statistics revealed no differences were comparing males in which selected players were similar to non-selected. Results from discriminant analyses also showed no discriminant function for male players. For females, selected players displayed higher off-ice fitness, on-ice agility and psychological characteristics. Nine performance markers were significantly discriminant, in favour of selected players. By integrating additional variables at Camps 2 and 3, Phase 2 analyses led to a deeper understanding of the selection process for both teams. In fact, some psychological characteristics and game performance indicators (2022-2023) were identified as discriminant variables to be retain in the selection process.

CONCLUSION: This study contributed to refine our understanding of talent identification in youth sport. Talent identification is a long-term process in which coaches and stakeholders need to consider the developmental aspects that contribute to attain high performance level in ice hockey. In this regard, evaluation camps should consider to assess the multiple components of sport talent. In addition, they should take account of players evolution in regard to these components. Further research is needed in terms of how the talent at this stage of development can be transposed for the next competition levels.

A COMPARISON OF SELF-REPORTED AND HEART RATE-BASED TRAINING IN JUNIOR ENDURANCE ATHLETES.

DE MARTIN TOPRANIN, V.1, NOORDHOF, D.A.2, BUCHER SANDBAKK, S.3, SOLLI, G.S.1

1 NORD UNIVERSITY, BODØ, NORWAY, 2 NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY, TRONDHEIM, NORWAY, 3 NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY, TRONDHEIM, NORWAY

INTRODUCTION: Analysis of training characteristics provides valuable information to understand the relationship between training stimulus and consequent (mal)adaptations. A common method for training analysis is the use of training diaries, where athletes usually self-report their training duration and intensity by manually allocating time to different intensity zones based on a combination of perceived exertion, heart rate (HR) and goal of the session (1). A nearly perfect correlation between self-reported (SR) and HR-based training duration was observed in senior elite endurance athletes, although athletes consistently SR a lower total training duration (2). However, the association between these two methods has not

been assessed among young less experienced endurance athletes. The purpose of the present study was therefore to compare SR and HR-based training data among junior endurance athletes.

METHODS: SR and HR-based training data of 24 (11 female, 13 male) competitive cross-country skiers and biathletes (17.2 ± 0.9yrs) were collected for all endurance sessions for two weeks during the preparation period. Training duration for HR-based data was calculated both as the total training duration recorded by each athlete's HR-device and the duration performed >55% of HRmax. HR-based data were allocated to intensity zones based on the intensity scale developed by the Norwegian Top Sport Centre: low intensity training (LIT), 55%–82% of HRmax, moderate intensity training (MIT), 82%–87% of HRmax and high intensity training (HIT), >87% of HRmax (3). The SR training duration and intensity distribution were collected from athletes' training diaries and categorized in a 3-zone intensity distribution. The association between SR and HR-based training data was tested using mixed model analysis.

RESULTS: Total training duration was significantly lower using the SR method (-10.74min, P<.001) compared to HR-based, whereas the opposite (7.62min, P<.001) was observed when training duration >55% of HRmax was analysed. LIT duration was significantly higher using the SR method (6.20min, P<.001) compared to HR-based and the same was observed for HIT (3.09min, P<.001), whereas MIT duration was lower using the SR method (-1.61min, P=.02) compared to HR-based.

CONCLUSION: These results confirmed previous findings in senior elite athletes (2) with regards to systematically self-reporting a lower total training duration and a higher training duration >55% HRmax. SR and HR-based methods were not concordant in terms of intensity distribution, which indicates they cannot be used interchangeably. The HR-based method likely does not capture the full picture of metabolic and perceptual events during training at different intensities, which might be better represented by the SR method.

SPORT-SPECIFIC TASKS AND GAME PERFORMANCE IN RELATION TO RELATIVE AGE AND BIOLOGICAL MATURITY IN TALENT SELECTION AMONG ADOLESCENT FEMALE HANDBALL PLAYERS

TRÓZNAI, ZS.1, UTCZÁS, K.1, PÁLINKÁS, G.1, JUHÁSZ, I.2, SZABÓ, T.2, PETRIDIS, L.1

1HUNGARIAN UNIVERSITY OF SPORTS SCIENCE, RESEARCH CENTER FOR SPORT PHYSIOLOGY, BUDAPEST PHYSIOLOGY, BUDAPEST 2HUNGARIAN HANDBALL FEDERATION, BUDAPEST

INTRODUCTION: It has been proposed that technical and tactical sport-specific tasks are not affected by maturity status and therefore can be considered for talent selection purposes. In this study, we examined in-game performance and sport- and position-specific tasks in relation to relative age and biological maturity during a talent selection process in handball. We tested the hypothesis that relative age and/or maturation have limited impact on talent selection.

METHODS: The participants (N=225) were adolescent female handball field players participating in the national handball selection (backcourts N=99, wings N=55, pivots N=21, center backcourts N=50). The selection included handball-specific generic skills, position-specific technical drills and the players performance in game situations. We grouped the players into eight categories in quarter-year intervals (from Q1-Q8). Biological maturity was estimated with an ultrasound-based device (Sunlight BoneAge). Differences between bone age (BA) and chronological age (CA) were used to estimate maturity status (delayed/average/advanced). Inter-group differences were examined by one-way analysis of variance.

RESULTS: Relative age groups differed in bone age in favour of relative older, but not in body size. Regarding selection criteria, differences between relative age groups were found only for in-game performance (Q1: 6.0±2.0 vs. Q8: 3.4±3.4 points; p<.002) and total score (Q1: 21.7±6.7 vs. Q8: 13.9±7.0 points; p<.003), but not for the technical tasks. When divided based on their maturity status, delayed maturing players had significantly lower performance in the slalom dribbling-shooting task than average maturing players (29.1±1.6 sec vs 27.7±1.7 sec respectively, p<.014) and also in the defensive footwork task than advanced maturing players (16.3±1.3 sec vs 15.5±0.8 sec respectively, p<.001).

CONCLUSION: The results confirm the disadvantage of the delayed maturing players in selection, primarily in those generic tasks where the relative contribution of physical abilities (force, speed, agility) is important for success. Maturation did not affect position-specific tasks and game performance. It seems that relative age has no effects on most tasks, despite that relative older players were older also in biological age. This may be explained by the similar variability in maturity status observed in all relative age groups likely resulting in homogenizing their performance. The significant differences in in-game performance scores between the relative age groups can be explained by the assumption that relatively older players have more training and competition possibilities developing in this way their game intelligence. In summary, it is not the relative age itself that affects the selection, but mostly advanced biological maturation of presumably above one-year differences between the players.

ILLNESS PREDICTION OF ELITE YOUTH SOCCER PLAYERS BASED ON BLOOD-BASED BIOMARKER DATA AND MACHINE LEARNING MODELS

KRANZINGER, S.1, KRANZINGER, C.1, HALLER, N.2,3, STÖGGL, T.4

1 SALZBURG RESEARCH FORSCHUNGSGESELLSCHAFT MBH, AUSTRIA; 2 UNIVERSITY OF SALZBURG, AUSTRIA; 3 UNIVERSITY OF MAINZ, GERMANY; 4 RED BULL ATHLETE PERFORMANCE CENTER, AUSTRIA

INTRODUCTION: Minimizing the risk of illness is of great interest in sport, e.g. soccer, as illnesses can lead to long absences during the season. The risk for developing illness has already been explained in studies by low fitness, high training load, or subjectively reported factors [1, 2]. The aim of our work was to investigate whether an emerging illness in soccer players can be predicted by a comprehensive panel of blood-based biomarkers collected on the days preceding the onset of illness using machine learning models.

METHODS: Data were collected from 23 soccer players of an elite European youth soccer team over a three-month period during the 2021/2022 regular season. In addition to 40 blood parameters (covering aspects of e.g., muscle damage, iron status, inflammation and immune response), information on the illness status of the players was regularly collected. To predict illness, five players were randomly selected as the training dataset and the remaining players were used as the test dataset for validation. The training dataset contained 10 illness and the test dataset contained two illness data points. To increase the number of illness cases in the training dataset, we used ADASYN [3] for oversampling. For prediction, we compared three machine learning models: random forest, linear support vector machines and a naïve Bayes classifier. To investigate the important variables for classification, we use the Receiving Operating Curve.

RESULTS: Linear supported vector machine achieved the best classification results. With this model one of the two illnesses present in the test data could be explained, which resulted in an accuracy value of 85%, recall of 50% and a Cohens Kappa of 0.10. Analysing the most important variables for classification reveals that illness is best predicted by Eosinophil, Ferritin, Glucose and C-reactive protein.

CONCLUSION: Although it is possible to predict illness of soccer players by using blood-based biomarker data and applying a linear support vector machine, the number of wrongly predicted illnesses is high. Nevertheless, when having more illnesses to train a model, machine learning approaches could help to detect illness signs in advance and thus react early if needed.

DIFFERENCES IN FUTURE SUCCESS AMONG PROFILES OF YOUTH ELITE SOCCER PLAYERS IN MULTIDIMENSIONAL PERFORMANCE ASSESSMENTS: A PERSON-ORIENTED APPROACH BASED ON DEEP LEARNING FACTOR AND CLUSTER ANALYSES

LEYHR, D., KILIAN, P., KELAVA, A., HÖNER, O.

UNIVERSITY OF TÜBINGEN

INTRODUCTION: Over the last decades, the prognostic relevance of performance assessments in talent identification and development (TID) programs in soccer is critically discussed in talent research. While a major part of studies deals with variable-centered approaches investigating the predictive value of single tests and/or their combination, also person-oriented analyses focusing on the player holistically, e.g., by examining player profiles, seem promising [1;2]. Therefore, the aims of the present study were (a) to explore different player profiles based on multidimensional performance assessments, and (b) to examine differences among those profiles regarding players' future success in youth elite soccer.

METHODS: The study sample consisted of N=6523 male U12 players participating in nationwide conducted multidimensional assessments (12 outcome variables) in the German TID program [3]. To address (a), a deep learning factor analysis identified four underlying latent factors behind the assessments: (1) subjective coach evaluations of players' tactical, technical, and psychosocial skills; (2) age-related and anthropometric measurements, (3) technical skills; and (4) speed abilities. Those were used to discover player profiles via a k-means-cluster analysis. Regarding (b), it was assessed, whether players transitioned into a U15 at a German youth academy three years after the assessment. 570 players (8.7%) met the criterion. Chi-square tests examined differences between identified profiles and success rates. Odds ratios for being selected (for each profile) served as effect size.

RESULTS: (a) The cluster analysis revealed six different player profiles: "Anthropometrically advanced high performers" (n=788), "Subjectively low rated, anthropometrically advantaged" (n=604), "Subjectively high rated and technically skilled" (n=1189), "Average performers" (n=1344), "Subjectively low rated players with low technical skills" (n=1157), and "Anthropometrically and technically below average" (n=1440). (b) Significantly different proportions of successful players among profiles were detected (p<.001). "Anthropometrically advanced high performers" obtained the highest chances for future

success (22.6%, OR=2.6, p<.05), while the lowest chances occurred for the profile "Anthropometrically and technically below average" (1.7%, OR=0.2, p<.05).

CONCLUSION: The results indicate differences in future success among the identified performance profiles of players. Similar to former variable-centered approaches, the person-oriented analyses confirmed the predictive value of the multi-dimensional performance assessments. Whether and to what extent benefits of the person-oriented approach (e.g., the potential to discover compensation effects) may provide valuable information for research and applied practice of TID processes needs to be examined in future studies.

PREDICTING FOOTBALL MATCH RESULT IN REAL-TIME BASED ON MACHINE LEARNING APPROACH

JIALE, W., YUESEN, L., JINYING, J., YIXIONG, C.

BEIJING SPORT UNIVERSITY

INTRODUCTION: Recent advances in sports technology have provided massive data on professional football matches that facilitates the investigation of competitive performance, which further allows for the generation of research aiming to predict the outcome of matches. However, it seems more practically useful and challenging if the real-time win probability of a team is objectively predicted when it comes to the analysis of match behavior and fan engagement. Therefore, the purpose of the study was to build an interpretable machine learning framework that enables in-game football match result prediction.

METHODS: The event data from 380 matches of the 2017-2018 English Premier League (EPL) and 64 matches of the 2018 World Cup were used. A total of 52 features from 9 categories were extracted every five minutes: offensive behaviors (shots, attacking passes, etc.), defensive behaviors (tackles, interceptions, etc.), playing styles (tempos, average team position, etc.), opponent attack behaviors (opponent shots, etc.), game situations (home goals, yellows, etc.), ball possessions, team ratings, historical game outcome, and team strength (ELO ratings, etc.). The current match status (win, lose and draw) for home team was used as the result label. The Light Gradient Boosting Machine (LGBM) was applied to model the match result of different periods, with the training set being 7953 observations from all EPL games and the test set being 1352 observations from all World Cup games (ratio of the training set to the test set: 8 to 2).

RESULTS: Within all result labels, home team was winning 44.8%, drawing 24.5% and losing 30.6% of all games. The statistics of the AUC, F1 and prediction accuracy of the model were 0.73, 0.50 and 0.64 respectively after training and validating. Specifically, the model successfully classified 471 out of 572 home wins (82.3%), 390 out of 590 home loses (66.1%) and only 11 out of 190 draws (5.8%) during the 2018 World Cup. Team strength and historical game results demonstrated higher feature importance. The game situation showed a moderate influence on the model, while the shots, clearance and ratings had the least contribution to the prediction of the model.

CONCLUSION: The study introduced an in-game football match result prediction framework that combines domain knowledge and data-driven model. In general, the proposed model showed decent prediction accuracy expect for the drawn matches where margin of victory for both teams is relatively low. In line with previous research, the score advantage in the game mainly depends on its own strength and the goals in previous games and will also be affected by the home court and penalty cards. The model could be applied into the real-time win probability during match broadcast or providing coaching teams with reference for decision-making.

EXPLORING THE EFFECT OF ARM SWING ON COUNTERMOVEMENT JUMP PERFORMANCE USING MACHINE LEARNING AND GROUND REACTION FORCE ANALYSIS

CHALITSIOS, C.1,2, NIKODELIS, T.1, KOLLIAS, I.2

1ARISTOTLE UNIVERSITY OF THESSALONIKI; 2KINVENT

INTRODUCTION: Jump performance is a requirement for many physical activities. The ability to accurately classify different jumping styles can provide valuable insights into an athletes performance and aid in the development of training programs. This study aimed to investigate the impact of arm swing on the observed pattern of ground reaction forces during a countermovement jump (CMJ) and determine if it can be used to improve the classification accuracy of jumping styles. Our hypothesis was that the presence of arm swing would result in different ground reaction force patterns compared to a countermovement jump without arm swing.

METHODS: Three hundred and thirty-two male adult high-level athletes from various sports performed a series of CMJ and CMJ with arm swing (CMJas) on a 1D force platform. A machine learning approach was adopted to analyze the force-time data recorded for each participant, using a random forest classifier [1]. The data were interpolated to 101 points and then transposed so that each force-time point represents a feature. SHapley Additive exPlanations (SHAP) analysis [2] was used to provide explanations about the models' predictions and insights about the most important features that best described each class force pattern. Also, to describe, interpret, and further explore the derived classification predictions, kinetic energy was calculated and statistically compared across the two jumps using the SPM1D paired t-test.

RESULTS: The classification accuracy was 0.895 (CI 95%: 0.869 - 0.921). The SHAP-based variable importance ranked all the features (time points) according to their value for the model, to predict the class (CMJ or CMJas). The model showed that all features (time points) from 83 – 94% of the total jump duration were the most important in distinguishing between the CMJ and CMJas. Also, the model pointed out that vGRF is highly informative in separating the two jumps after 65% of the total jump duration. Further statistical analysis of the data revealed a significant difference in the produced kinetic energy with the CMJas prevailing from CMJ at ~90-100% ($t = 3.249$, $p < 0.05$) of jump duration.

CONCLUSION: These findings confirmed that arm swing discriminates countermovement jumps, especially in the last part of the task. They also support the efficacy of the machine learning modeling approach for understanding the complexities of vGRF patterns in a laboratory setting. Overall, the work produced during the late phase of CMJ with arm swing produces a very distinct peak, which the classifier can capture and separate into two classes. Contrary to previous reports, no informative features were found before 65% of the jump duration, likely linked to the inconsistency due to the high variance of the force patterns during the unweighing and braking phases of both jumping techniques.

OP-PN27 Energy Restriction and Weight Loss

RAPID WEIGHT LOSS BEHAVIOR IN JUDO ATHLETES: PREVALENCE, MAGNITUDE, AND METHODS.

SANTOS, D.F.C.1, FRANCHINI, E.1

1MARTIAL ARTS AND COMBAT SPORTS RESEARCH GROUP, SPORT DEPARTMENT, SCHOOL OF PHYSICAL EDUCATION AND SPORT, UNIVERSITY OF SÃO PAULO, BRAZIL

INTRODUCTION: Rapid weight loss (RWL) is characterized as a reduction of body mass equal to or above 3% in up to 7 days. The typical magnitude of reduction is about 5% of body mass, although some athletes may reduce up to 10% before competition [1]. There is limited information about the prevalence, magnitude, and methods of RWL since the judo weigh-in was changed to the day before competition, and it is believed that athletes altered their behaviors due to the extended recovery time.

METHODS: This study involved 223 judo athletes who were over 18 years of age and actively competing. Participants were required to complete a validated RWL Questionnaire (RWLQ)[2] that included questions about personal information, competitive level, weight and diet history, and RWL behaviors. The questionnaire had a scoring system where a higher score indicated more aggressive weight management behavior. Participants were recruited through online forms and during official competitions. The Mann-Whitney U-test was used to compare scores between the sexes, and a one-way ANOVA was used to compare scores between athletes who started cutting weight at different ages and levels of competition.

RESULTS: The prevalence of RWL was 90% when all athletes were included and 93% when heavyweights were excluded. On average, athletes lost 4.94% (range: 0-24%) of their body mass 3-5 days before competition. A significant number of athletes (40%) reduced more than 5%. When asked about their greatest weight loss, athletes reported a mean reduction of 8% (range: 0-24%) of their body mass. Approximately 50% of athletes regained 2-3kg (2-6%) in the week after the competition, and about 37% regained more than 3 kg (3-13%). The most common methods used were increased exercise, training with plastic or rubberized suits, and decreased fluid intake. The athletes weight management behavior was most influenced by the judo coach, dietitians, and training colleagues. When separated by age, athletes who started cutting weight earlier had a higher score on the RWLQ ($P=0.002$), but no significant differences were found between males and females ($P=0.285$) or between competitive levels ($P=0.378$).

CONCLUSION: The prevalence of RWL in judo athletes is slightly higher than previously reported before the weigh-in rule changed [1]. However, the magnitude of RWL is similar for most athletes, and a growing number of athletes are reducing more than 5% of their body mass.

EFFECTS OF THE FUEL INTERVENTION ON MENSTRUAL FUNCTION IN COMPETITIVE FEMALE ENDURANCE ATHLETES WITH RISK OF RELATIVE ENERGY DEFICIENCY IN SPORT

FAHRENHOLTZ, I.L., MELIN, A.K., GARTHE, I., IVARSSON, A., KOEHLER, K., LOGUE, D., MADIGAN, S., WASSERFURTH, P., TORSTVEIT, M.K.

UNIVERSITY OF AGDER, KRISTIANSAND

INTRODUCTION: Female endurance athletes are at high risk of menstrual dysfunction (MD) due to problematic (long-term/severe) low energy availability (LEA). MD has been associated with reduced bone health and performance in female endurance athletes, emphasizing the need for management of problematic LEA and associated conditions such as MD.

METHODS: Female competitive endurance athletes from Norway (n=60), Sweden (n=84), Ireland (n=17), and Germany (n=47) were recruited to the Food and nUtrition for Endurance athletes – a Learning (FUEL) program consisting of 16 weekly

online lectures and individual athlete-centered nutrition counseling every other week. Fifty athletes with symptoms of REDs [LEA in Females Questionnaire (LEAF-Q) score ≥ 8] and with low risk of eating disorders, with no use of hormonal contraceptives and no chronic diseases, were allocated to either the 16-week FUEL-intervention (n=32) (FUEL) or a 16-week control period (n=18) (CON). All but one completed the FUEL-intervention, while n=3 dropped out during CON. Athletes completed the LEAF-Q with menstrual function questions, at pre- and post-intervention/control period, and also at 6- and 12-months follow-up for the FUEL group. Menstrual function was analyzed in a descriptive manner, while group comparisons of LEAF-Q menstrual score from pre- to post, as well as within FUEL group comparisons for the four measurement time points, were conducted using a Bayesian mixed factor analysis of variance.

RESULTS: Self-reported eumenorrhea increased from 10% (n=9 athletes) at pretest to 67% (20 athletes) at posttest in FUEL and decreased in CON from 73% (n=11) to 53% (n=8). Five of the 14 (36%) FUEL athletes, who reported MD at pretest, reported eumenorrhea at posttest. Seven (23%) FUEL athletes and three (20%) CON athletes were unaware whether they had normal menstruation at pretest. All FUEL athletes were able to define whether they had normal menstruation at posttest, while the number was unchanged for CON athletes. The number of athletes who reported reduced or absence of menstrual bleedings with increased training load decrease from 70% (n=21) to 47% (n=14) in FUEL while the number 73% (n=14) was unchanged in CON.

Changes in the LEAF-Q menstrual score from pre- to post did not differ between groups, as indicated by the lack of an interaction effect (FUEL: 6.6 ± 2.5 at pre- and 5.3 ± 3.0 at posttest versus CON: 5.1 ± 2.7 at pre- and 4.7 ± 2.3 at posttest, BFincl = 0.664). Six- and 12-months follow-up revealed strong evidence (BFincl = 860) for improvement in LEAF-Q menstrual score for FUEL athletes comparing all four measuring points (4.6 ± 2.6 at 6- and 5.1 ± 3.1 at 12-months follow-up).

CONCLUSION: In this group of endurance athletes, participating in the FUEL intervention implies long-term improvement of menstrual function. The lack of long-term follow-up for the CON condition indicates, however, that the results should be interpreted with caution.

ANALYSIS OF FOOD INTAKE DURING A 20-DAY EXPEDITION IN THE COLD

CHARLOT, K.

INSTITUT DE RECHERCHES BIOMÉDICALES DES ARMÉES

INTRODUCTION: To achieve neutral energy balance and avoid body mass loss during a period with high and sustained physical activities might be hard even in comfortable ecological conditions and/or with easy access to food with an energy content exceeding the energy demands. The reasons of this under consumption are multiple and mostly contextual but are rarely studied. The aim of this study was to identify these reasons using a military 20-day ski expedition in Greenland.

METHODS: Twelve French soldiers realized a 20-d ski expedition in Greenland (-5 to -25°C) during which they were fed with 3750-kcal lyophilized rations (7 different menus composed of easy-to-use, highly palatable and familiar foods) insufficient to cover their expected energy expenditure (~4500 kcal). Each day, in a paper notebook, they had to report foods and beverages intake in order to calculate energy intake. They also had to indicate the time of intake, the palatability of each consumed items (from 1 to 10) and the reason(s) they did not consume some items. Appetite was assessed using visual analog scales before breakfast and dinner. A body mass and composition measurement was done just before and the day after the expedition. The 20 days were cut in 3 parts (D1-D7; D8-D14 and D15-D20) and the food items were separated in breakfast, day sweet, day savory, and dinner items for analyses.

RESULTS: Participants experienced a mean negative energy balance of -975 ± 550 kcal during the expedition leading to a 4.2 ± 1.9 kg ($p < 0.001$) body mass loss. A temporal analysis revealed that energy intake ($p = 0.033$) and hunger levels ($p < 0.001$) were higher during the last week compared to first one during the expedition. The percentage of consumed items rose from 86 to 90% between the first and third weeks, this increase concerning mostly savory day and dinner foods (87 to 91, and 81 to 91%, respectively). In agreement, palatability increased only in savory day ($p < 0.001$) and dinner ($p = 0.048$) foods. The reasons for not consuming an item were: 1) the food being not sufficiently good and/or practical (33%) and the lack of appetite (33%), 3) their conservation in case of needs (15%), 4) the lack of time (13%), and 5) the weariness (6%).

CONCLUSION: Despite experiencing large body mass loss, these participants only slightly and very insufficiently adapted their food intake. Interestingly, the lack of appetite and the lack of palatability came as the main reasons for not consuming foods suggesting that body mass loss does not transpose well into an increase in food flexibility. Moreover, the increase of palatability and frequency of consumption was mostly targeted towards savory foods (during the day and dinner) pointing point out means to improve rations compositions and limit body mass loss.

POSITIVE ASSOCIATION BETWEEN T3 AND RESTING ENERGY EXPENDITURE IN FEMALE CROSSFIT PRACTITIONERS: DOES IT PRECEDE THE FEMALE ATHLETE TRIAD? PRELIMINARY DATA FROM AN EXPLORATORY CROSS-SECTIONAL STUDY.

NAKAMOTO, F., CRISTOFOLINI, V.L., SANTOS, C.S., RODRIGUES, A.S., STAIBANO, A., ROSSI, C.B., ALVARES, L.A.M., FERREIRA, R.E.S., SANTOS, R.V.T., QUARESMA, M.V.L.S.

CENTRO UNIVERSITÁRIO SÃO CAMILO

INTRODUCTION: CrossFit® (CF) is characterized as a constantly varied, high-intensity, functional movement training program, performed with little or no rest between bouts, combining strength and endurance exercises, such as running, cycling, rowing, Olympic weightlifting, power weightlifting, and gymnastic-type exercises. Due to CF characteristics, female CF practitioners may be at risk to experience low energy availability (LEA), which is the etiological process underpinning

the development of the Female Athlete Triad (FAT). The aim of this study is to verify if female CF practitioners are at risk for the FAT.

METHODS: This is a cross-sectional study with nonprobability sampling. Inclusion criteria: healthy female CF practitioners aged 18-39 years, minimum of 5 training sessions per week for at least 6 months; minimum CF training experience of 1 year. Exclusion criteria: women taking any substance that interferes with the menstrual cycle. Subjects visited the laboratory once. They initially answered a health and sociodemographic questionnaire. Resting energy expenditure (REE) via indirect calorimetry (K5, COSMED®) and body composition (Bioelectrical impedance analysis; model 450®, Biodynamics) were assessed in a fasting state, followed by a blood test (levels of IGF-1, T3, and leptin) and the Low Energy Availability in Females Questionnaire (LEAF-Q). Data were analyzed using Jamovi® 2.3.21 version. A sample size of 42 subjects was calculated.

RESULTS: Subject characteristics (mean (DP); n = 14): Age: 32.1 (5.45) y; IMC: 23.7 (1.57) kg/m2; % body fat: 22.6 (3.45); REE: 1589 (146) kcal; IGF-1: 164 (54.8) ng/mL; Leptin: 12.8 (10.1) ng/mL; T3: 1.05 (0.319) ng/mL; LEAF-Q score: 3.86 (2.80). More than 70% REE variability is explained by multiple regression model (R2: 0.77; p = 0.040). After controlling for age, IGF-1, and leptin, the linear regression model showed T3 was positively associated with REE (B = 254.32 kcal; 95% IC: 12.14 - 486.52; p = 0.042). On the order hand, this model was not associated with the LEAF-Q score.

CONCLUSION: Our preliminary data showed a positive association between T3 levels and REE, even with our small sample size. It is well known that thyroid hormones are of central importance for energy homeostasis and metabolism. They directly stimulate energy expenditure, which means that low levels of thyroid hormone decrease REE and high levels increase REE. So far, LEAF-Q results did not show risk of FAT among female CF practitioners. Low T3 levels may be an important predictor of low REE among CFP and consequent low REE might precede other perceived disturbances associated with FAT in this population. Our results are preliminary, and more data is required for a better comprehension of this important topic, especially in CF practitioners.

Oral presentations

OP-SH24 Physical education and health

MODELING SPORTS-RELATED HEALTH COMPETENCE FOR PHYSICAL EDUCATION

HINTERNESCH, S.

TU DORTMUND UNIVERSITY

INTRODUCTION: Health promotion has always been of particular interest in physical education research. Especially in the course of competence orientation in didactics, there is currently a shift in Germany towards the goal of promoting students sports-related health competence. Although the tripartite nature of the competence dimensions is largely consensual at a theoretical level ("knowledge, ability and willingness"), there is however a strong focus on knowledge tests when it comes to competence assessment (e.g. Töpfer & Sygusch, 2022). The following research question is addressed: How can the dimensions of ability and willingness be captured in addition to knowledge testing to enable a comprehensive investigation of sports-related health competence?

METHOD:

With the overall aim to develop a holistic survey method for the sports-related health competence of students, a multimethod validation procedure is used (Jenßen et al., 2015). In a first step, a draft of an adapted model of sports-related health competence for physical education (based on Blömeke et al., 2015) was put up for discussion in qualitative expert interviews with scientists in the field of sports pedagogy, educational and health science (N=10). Important prerequisites for holistic competence assessment have been discussed. Qualitative content analysis is used for the evaluation. The presentation focuses on these interview results, which shall be used in a second step to develop the survey methodology.

RESULTS: Based on the findings of the content analysis, the adapted model was revised. Individual dimensions of the model of sports-related health competence (e.g. body awareness) and their function for health-related action of students have been identified. The experts stressed the importance to link the contents of knowledge and ability testing closely when aiming to test the sports-related health competence in a holistic way. Motivational-volitional dimensions were attributed different importance by the experts. Another finding is that the capability to act, as a potential goal of promoting sports-related health competence in physical education, has to be distinguished from the actual actions of the students in everyday life (performance).

DIFFERENCES BETWEEN YOUNG CHILDREN'S ACTUAL AND PERCEIVED MOTOR COMPETENCE REGARDING SKILL PERFORMANCES ON LAND VERSUS IN WATER: A CROSS-SECTIONAL STUDY

DHONDT, E.1, MERTENS, L.1,2,3, VAN DROOGENBROECK, L.1, COPPENS, E.2, DE MARTELAER, K.1

1. VRIJE UNIVERSITEIT BRUSSEL, 2. UNIVERSITEIT GENT, 3. RESEARCH FOUNDATION - FLANDERS

INTRODUCTION: Both actual motor competence (AMC) and perceived motor competence (PMC) are positively associated with physical activity in children [1]. Despite the importance of accurate estimates of aquatic skills in view of water safety from an early age onwards, research has mainly focused on children's self-perceiving ability in relation to their AMC regarding land-based skill performances. Therefore, the purpose of this cross-sectional study was to simultaneously document and compare young children's AMC and PMC in different movement contexts (i.e., on land vs. in water).

METHODS: Data were collected from 92 children (42 girls, 50 boys; aged 6.8 ± 0.4 years) attending primary schools for regular education near Brussels (Belgium). All participants' AMC and PMC in terms of skill performances on land versus in water were assessed using aligned instruments per movement context. Children's land-based AMC was evaluated by means of the third version of the Test of Gross Motor Development (TGMD-3) [2], whereas their land-based PMC was examined using the updated version of the Pictorial Scale of Perceived Movement Skill Competence for Young Children (PMSC) [3] matching the 13 TGMD-3 test items. Children's water-based AMC was evaluated by means of the Actual Aquatic Skills Test (AAST) [4,5], during which they performed exactly the same 17 aquatic skills as presented in the Pictorial Scale of Perceived Water Competence (PSPWC) [6] used to examine their water-based PMC. All raw total test scores were re-scaled to achieve a comparable score range of 0-100 across the different assessment tools. A three-way Repeated Measures ANOVA compared children's AMC and PMC (i.e., skill assessment type) according to movement context, also taking their sex into account.

RESULTS: There was a significant interaction between skill assessment type and movement context as within-subjects factors ($p < .001$), indicating significantly higher PMC as compared to AMC scores with a greater extent of disagreement between these outcomes on land ($p < .001$; land-based AMC = 73.96 ± 10.83; land-based PMC = 89.99 ± 12.18) versus in water ($p = .044$; water-based AMC = 72.95 ± 19.93; water-based PMC = 77.53 ± 12.14). Children's land-based PMC was also significantly higher than their water-based PMC score ($p < .001$), whilst this equally directed difference according to movement context was not significant for AMC scores ($p = .679$). No sex effects were found.

CONCLUSION: Young children proved to overestimate their actual skill performances in both movement contexts. This perceptual error or extent of disagreement between AMC and PMC was more pronounced on land than in the aquatic environment. A promising research avenue is to apply a person-centered approach using cluster analysis to gain more insight in divergent/convergent MC-based profiles within and perhaps across contexts.

ASSOCIATIONS OF REGULAR PHYSICAL ACTIVITY WITH PHYSIOLOGICAL AND PSYCHOLOGICAL STRESS REACTIVITY IN CHILDREN AGED 10-13 YEARS

HANKE, M., BRUGGISSER, F., LEUENBERGER, R., GERBER, M., LUDYGA, S.

UNIVERSITY OF BASEL

INTRODUCTION: High stress reactivity can be detrimental for physiological and psychological health. According to the cross-stressor-adaptation hypothesis, physical activity has health-beneficial effects on psychosocial stress reactivity. However, studies investigating such effects in children are scarce. Therefore, our study aimed to investigate the association of regular physical activity with physiological and psychological stress reactivity in children.

METHODS: One hundred and ten (62 male) right handed children aged 10-13 years were recruited from schools and through distribution of flyers in public places. On two different laboratory appointments, scheduled in randomized order, the Trier Social Stress Test for Children (TSST-C) and a non-stressful control task were performed. Heart rate variability (RMSSD, measured via chest belt) and salivary cortisol (samples taken directly before and 0 min, 15 min and 30 min after the task) represented physiological stress reactivity. State anxiety was measured before and after the task with an 8-item questionnaire based on the state scale of the State-Trait Anxiety Inventory. Actigraphs worn over the course of 7 days were used to quantify moderate-to-vigorous physical activity (MVPA).

RESULTS: A median split was performed on MVPA, and separate analyses of variance were calculated with MVPA group and sex as between subject factors. For all stress parameters, significant main effects of condition indicated higher stress reactivity in the TSST-C compared to the control task ($p<.001$). A significant between subject effect of MVPA group ($F(1, 105) = 3.98$, $p = .049$, partial eta^2 = 0.037) indicated lower cortisol reactivity in children with higher MVPA. A similar tendency was observed for heart rate variability ($F(1, 99) = 3.42$, $p = .067$, partial eta^2 = 0.033). All other associations and interactions with MVPA were not significant. Significant sex differences were observed for cortisol and anxiety, with boys reacting more to the control task and less to the TSST-C compared to girls.

Discussion/CONCLUSION: The results of our study indicate a health-beneficial association of higher levels of MVPA with children's physiological response to a psychosocial stressor. Programs targeting stress reduction in children should take potential sex differences in stress reactivity into account. Further longitudinal and intervention studies are necessary to confirm potential causal relationships.

EXPLORING LINGUISTIC DIMENSIONS THROUGH EXPLORATORY CIRCUS ASSIGNMENTS IN PHYSICAL EDUCATION

LINDBERG, M.

MALMÖ UNIVERSITY

Introduction

Limited language skills are problematic for learning to occur. Teachers should carry out literacy teaching that enhances pupils' language development but consider themselves too busy with teaching subject content (Moje 2008). According to physical education (PE) teachers, the primary goal is to physically activate the pupils. Research shows that language integrated PE can assist children's language development (Derri et al. 2010). However, language integrated PE lowers the time for physical activity (Coral et al. 2020). This is problematic since youth's physical inactivity is a growing problem. This study examines how disciplinary literacy in a multilingual PE context can be emphasized and the pupils' use of verbal language stimulated to enhancing learning in PE and to understand how it can steer teaching and learning processes in certain directions.

Methods

Multilingual 10-year-old pupils and their PE teacher participated with a research teacher in 10 PE lessons focusing on language integrated exploratory circus assignments. Data was collected through participant observation, video observation, interviews, and field diary. The data analysis was abductive, which meant an oscillating backwards and forwards between the theory and the data. A thematic analysis was carried out.

Results

The tentative results show that there were both opportunities and challenges when emphasizing disciplinary literacy in PE. Time focused on language was needed for all pupils to partake and develop knowledge, but it happened on the expense of physical active time. Such endangering was bridged through additional time for anchoring the language and creating pre-understanding beforehand the PE lesson.

Discussion

The PE subject's focus on physical activity can be considered a "free zone" from the theorizing ambition to emphasize language learning. This study question whether there is a paradox embedded in such a thought, namely: only when you do not try to force PE and language together, language does come into its own. Physical doing is also learning, and the reflection of the action makes pupils reach new levels in doing things in PE. This study highlights that involvement of language is important in PE – not for the language itself, but because it enables learning and enhances knowledge development in PE.

PHYSICAL LITERACY IN GERMAN CHILDREN

KNISEL, E.1, LAUDANSKA-KRZEMINSKA, I.2, NALECZ, H.3, WAGNER, P.4, BREMER, M.1

1OTTO-VON-GUERICKE UNIVERSITY OF MAGDEBURG, 2POZNAN UNIVERSITY OF PHYSICAL EDUCATION, 3INSTITUTE OF MOTHER AND CHILD, WARSAW, 4UNIVERSITY OF LEIPZIG

Introduction

Physical literacy (PL) is a concept attracting worldwide attention in the context of Physical Education (PE), sport and health. It is described as the motivation, confidence, physical competence, knowledge and understanding to be physically active for life. The Canadian Assessment of Physical Literacy, second edition (CAPL-2) (Longmuir et al., 2018) is a valid and reliable instrument to assess physical literacy in children. The aim of our study is a gender-and age-stratified analysis of PL in German primary school children.

Method

332 (172 girls, 160 boys) German primary school children aged 8-12 years old (M=11.05 SD=0.98) participated in the study. PL was measured using the German version of the Canadian Assessment of Physical Literacy, second edition (CAPL-2-G). CAPL-2-G consists of a questionnaire to assess the Knowledge and Understanding and Motivation and Confidence domains. The Daily Behavior domain was assessed from one self-report item of weekly physical activity and step counts during one week. To study the Physical Competence domain three physical tests were applied.

Results

The results for the overall physical literacy score (maximum 100 points) demonstrate significant differences (U=2452; z=-2.068; p= .039; r=.17) between girls (n=82; M=66.32; SD=11.94) and boys ((n=74; M=70.99: SD=14.57). No significant age-specific differences were found. According to the four domains the results show significant gender-differences in the

Physical Competence (girls n=150; M=19.15; SD=5.64; boys n=142; M=21.38; SD=6.26; U=8036; z=-3.625; p=.000; r=.2; maximum score 30 points) and Daily Behaviour domain (girls n=83; M=14.86; SD=6.58; boys n=74; M=17.27; SD=6.82; U=24888; z=-2.052; p=.040; r=.16; 30 points maximal score). Only in the domain of Knowledge and Understanding (N=332) the data reveal significant differences within the age groups (F=2.72 p=.045) with the highest mean value in the 11-year-old age group (n=132; M=6.7; SD=1.86; maximum score 10 points).

Discussion

The gender-and age-stratified analysis of PL in German primary school children illustrates gender differences. The boys overall level of PL was higher than that of the girls and the 11-year old boys reached the highest PL overall score. The results show that the boys are more physical active than the girls and their level of physical competence is higher. This is also found in many international studies recently. The holistic concept and the assessment of PL in German primary school children provide a useful approach for structuring learning processes in PE class to improve a physically active lifestyle. And, our results can be the background for a discussion about co-or mono-educational teaching in PE class.

IS-PN05 Movement as Mitochondrial Medicine: new insights from traditional mitochondrial measures and the latest 'omic' techniques

MOLECULAR REGULATION OF MITOCHONDRIAL ADAPTATIONS TO EXERCISE

ZIERATH, J.

KAROLINSKA INSTITUTE SWEDEN, CBMR, UNIVERSITY OF COPENHAGEN, DENMARK

It is well established that endurance exercise training induces mitochondrial biogenesis in skeletal muscle, with a concomitant increased skeletal muscle mitochondrial capacity. These adaptations are mediated by a complex interplay between a myriad of signalling pathways coupled to downstream regulators of gene transcription and translation. On a regulatory level, a single session of exercise alters the DNA binding activity of a variety of important transcription factors. Protein stability and subcellular localisation of transcriptional factor complexes within the nucleus and mitochondrion are also affected. Transient DNA hypomethylation of gene-specific promoter regions also precedes some of the increases in mRNA expression in response to acute exercise. In turn, these pulses of elevated mRNA during the recovery from acute exercise facilitate the synthesis of respective proteins, and provoke gradual structural remodelling and long-term functional adjustments of the mitochondria. This presentation, by one of the leading experts in the world, will provide an up-to-date review of the molecular mechanisms that underpin the adaptation of skeletal muscle mitochondria to a single session of exercise and exercise training. The target audience will be both exercise and sport scientists with an interest in the mechanisms that underlie adaptations to exercise training.

THE EFFECTS OF DIFFERENT TYPES OF EXERCISE ON MITOCHONDRIAL ADAPTATIONS

DAUSSIN, F.

UNIVERSITY OF LILLE

Mitochondria are living, dynamic, energy-producing and signalling organelles that actively adapt to environmental inputs such as exercise. Mitochondrial biogenesis is defined as the process leading to the production of new mitochondrial components, and it is possible to evaluate the effects of exercise training on mitochondrial biogenesis by assessing changes in mitochondrial content and respiratory function. The effects of exercise training on mitochondria are controversial; some studies have observed changes in mitochondrial respiratory function without changes in mitochondrial content, other studies have reported the opposite effect, and some studies have observed an increase in both parameters. It has been suggested that the exercise modality used may partially explain these divergent adaptations to different training programs. This presentation will summarise how the following exercise modalities influence mitochondrial adaptations: i) high-intensity interval exercise (HIIE) - defined as efforts performed at an intensity between 80 and 100% of power/velocity associated with VO2max, ii) moderate-intensity continuous exercise - characterised by exercise performed in a continuous manner and at a lower intensity than HIIE, and iii) sprint interval exercise - repeated efforts performed at an intensity greater than power/velocity associated with VO2max. The current literature suggests that training volume will mainly improve mitochondrial content, while the training intensity will be the major determinant of changes in mitochondrial respiratory function. In this talk, Dr Daussin will summarise our understanding of the effects of different exercise modalities on mitochondrial adaptations. In addition, he will highlight some considerations, such as the training organisation, the role of sex, and fibre-type recruitment during exercise, that may influence mitochondrial adaptations to exercise. The

target audience will be both exercise and sport scientists with an interest in the prescription of exercise to improve health and performance.

USING OMICS TO UNDERSTAND MITOCHONDRIAL ADAPTATIONS TO DIFFERENT TYPES OF EXERCISE

BISHOP, D.
VICTORIA UNIVERSITY

Given the importance of mitochondrial biogenesis for skeletal muscle performance, considerable attention has been given to understanding the molecular changes that help to determine mitochondrial adaptations to exercise. In this session, Prof. Bishop will present published and unpublished 'omics data that provide new and exciting insights into the many molecular changes that contribute to exercise-induced mitochondrial adaptations. The results of RNA sequencing (RNA-seq) based transcriptomics highlight how different mitochondria-related gene transcripts respond following different types of exercise, and how this may help to explain divergent mitochondrial adaptations to different types of exercise training. These RNAseq results also indicate that there are transcriptional responses that are shared across different exercise prescriptions. Of particular interest is how exercise-induced mitochondrial damage activates transcriptional pathways associated with mitochondrial stress and how this may help to explain the powerful effects of very high-intensity exercise to improve mitochondrial respiratory function. The results of training studies incorporating whole-muscle proteomics will then be used to highlight an intricate and previously undemonstrated network of differentially prioritised mitochondrial adaptations that occur in response to different types of training. It will be shown that changes in hundreds of transcripts, proteins, and lipids are not stoichiometrically linked to the overall increase in mitochondrial content. Finally, the results of single-fibre proteomics show how exercise intensity influences fibre recruitment and ultimately induces fibre-specific changes in mitochondrial proteins that can help to explain how different types of exercise induce divergent mitochondrial adaptations. Finally, this presentation will highlight how these exciting new tools can help exercise and sport scientists to better understand how best to prescribe exercise to achieve specific mitochondrial adaptations. The target audience will be both exercise and sport scientists with an interest in the mechanisms that underlie adaptations to exercise training.

OP-AP43 Paralympics

PACING PROFILE BY CLASSIFICATION IN ELITE PARACYCLING

LE TOQUIN, B., SCHIPMAN, J., HAMRI, I., FORSTMANN, N., BACONNAIS, M., WEISSLAND, T., TOUSSAINT, J.F.
INSEP

INTRODUCTION: Pacing profile in cycling and paracycling studies can provide insight into the underlying physiological processes during specific events. In elite paracycling, it can also give insight into the effect of classification (thus disabilities) on cycling performance. Furthermore, analysis of the pacing strategies employed by successful athletes can provide information on optimal pacing strategy for a given event, and suggest opportunities for performance enhancement. This study aims to 1/ investigated the effect of classification on the pacing profile used in paracycling track events. 2/ analyze the pacing strategy of world championship medalists.

METHODS: All the results and split times (every 125m) of male (525 performances) and female (261 performances) paracyclists in 6 world championships from 2014 to 2022 have been collected on the RSStiming website. Data are based on the 1km Time Trial (TT), 500m TT and Individual Pursuit (IP) events. Analysis of variance with repeated measures was used to examine differences in 250m split times during IP events and differences in 125m split times during the 1km TT and 500m TT. Post-hoc analysis was performed using Student's t test for paired data, with alpha adjusted by the Bonferroni method. In order to analyse the decay kinetics of the speed over the course of an event, a speed decrease index (SPI) was calculated for each performance. Finally, to investigate if there were any differences in the pacing strategies between medalists and non medalist. The performance data from each world championships was split into 3 groups (Top 3; Top 8; Top 20) in each classification. A pairwise Wilcoxon test with Bonferroni adjustment to identify differences between each performance group was used.

RESULTS: First lap mean speed (0-250m split) and second lap (375-500m) was significantly different between classification ($p<0.05$) in each male and female event. In 1km TT, each classification reaches mean top speed in 375-500m before losing speed suggesting an identical pacing strategy. Pacing profile in each event suggest an «all-out» strategy and was not different between classifications. No significative difference between classification was found in SPI in each event ($p > 0.05$). However, a significative difference was found between the Top 3 and Top 8 SPI ($p<0.05$) in male and female individual pursuit events in C5 and C4 classification.

CONCLUSION: This study provides insights into the impact of paracycling classification system in para-cycling. In C5 and C4 classification, this study suggests that the best performers seem to be differentiated by their ability to not lose velocity during the race. The significant differences between each category during the first 2 laps indicate an impact of the classification (and thus of the disability) on the start.

HOW TO BE A FINALIST IN THE 3-POSITION RIFLE EVENT IN PARA-SHOOTING?

SCHIPMAN, J., BACONNAIS, M., SAUVEPLANE, V., CHAUSSÉ, M., FORSTMANN, N., TOUSSAINT, J.F.

INSEP

INTRODUCTION: The Paralympic mens 50m 3-position rifle event (R7) is performed in the following order: kneeling, prone and standing. In the prone position, both elbows are placed on a support, which offers stability. On the contrary, in the standing position, neither elbow is supported. 120 shots are fired in the qualification round (12 series of 10 shots), i.e. 40 shots per position. The maximum value per shot is 10.9 points, that is a theoretical maximum of 436 points per position for a total of 1308 points at the end. Following the qualification phase, the 8-best para-shooters advance to the final. The objective of this study is to analyze if one position among the three is discriminating between the para-shooters who reach the final (finalists) and those eliminated in the qualification phase (non-finalists).

METHODS: 29 competitions between 2014 and 2022 were collected on the international competition results website (SIUS Shooting), representing 716 performances by 76 para-shooters. The number of points obtained per position was added up to create three performance indicators for each position.

To analyze and quantify the difference in profiles between finalists and non-finalists, a Bayesian Inference via Markov Chain Monte Carlo was used from estimates of the posteriori distribution of θ (θ = (θ1, θ2, ..., θn), i.e., all parameters) and credibility intervals (θ be in the interval [a; b] with probability (1 -α)). Differences in mean scores were investigated between each sample pair for the finalist and not finalist groups (kneeling vs. standing, prone vs. kneeling, prone vs. standing).

RESULTS: Among the finalists, the mean differences in scores between the kneeling vs. standing and prone vs. kneeling positions are 7,7 and 7,2 respectively. Between the prone vs. standing positions, the difference in means is higher, at 14,8.

Among the non-finalists, the mean differences in scores between the kneeling vs. standing positions is 13,9, between the prone vs. kneeling positions is 11,5 and between the prone and standing positions is 26.0.

Between finalists and non-finalists, in the kneeling position, the difference in mean scores is 10,7. In the prone position, the difference in mean scores is 6,3. In standing position, the difference in mean score is 16,7. From the first 4 heats (kneeling), the finalists start to stand out. The next 4 heats (prone) maintain the gap between the para without increasing it. Finally, the last 4 heats (standing) widen the gap between the finalists and the non-finalists.

CONCLUSION: Bayesian analysis showed that there is a significant difference in profiles between para-shooters. The non-finalists show significant differences between the three positions. Finalist para-shooters shot better in the prone position than in the standing position, better in the kneeling position than in the standing position, and better in the prone position than in the kneeling position. Conversely, although there was a significant difference between the prone and standing positions,

KATA SELECTION OF INTELLECTUALLY IMPAIRED ATHLETES AT THE TOP-LEVEL PARA-KARATE COMPETITIONS

AUGUSTOVICOVA, D., STYRIAK, R.

COMENIUS UNIVERSITY

INTRODUCTION: Para-karate made its debut at the World Championships in Linz 2012 and since then it has been an integral part of the WKF Senior World Championships, which take place every two years. The top-level kata performance analysis is common [1,2], but there is limited knowledge of performance structure in top-level para-karate kata competitions for intellectually impaired (II) athletes. Repetition of the same kata is allowed for II athletes [3].

The main goal of the study is to describe the type and frequency of performed katas at the three consecutive World (2016, 2018, 2021) and four European (2018, 2019, 2021, 2022) para-karate championships. Then, investigate if there is a relationship between the sport class (II athletes and II athletes with Down syndrome) and the kata selection.

METHODS: All performed katas during seven top-level events were recorded. Competitors gender, name of the performed kata, and sport class were recorded. A chi-square test and descriptive statistics were conducted. A total of 245 kata were performed (153 in the male and 92 in the female category).

RESULTS: The most performed katas were Gojushiho Sho (29%), the same as in able-bodied kata competition, followed by Jion (9%), Suparinpei (9%), Chatanyara Kushanku (8%), and Sansai (7%). There is a significant relationship between sport class and choice of katas ($p \leq 0.05$). The Jion kata is not found in able-bodied competition. Athletes with Down syndrome select for the competition katas with lower athletic and technical levels, with a lower fast-slow movement ratio [4]. Only 5 athletes perform two different katas during one competition.

CONCLUSION: Top-level II athletes have a similar kata selection as the no-impaired karate athletes. The WKF Para-karate rules allow the repetition of the same kata during all rounds of the competition. Therefore, II athletes and their coaches prefer to use only the one and the most challenging kata to succeed with a lower rate of fast-slow movement ratio.

This abstract is a part of the VEGA project (number 1/0611/23).

IMPACT OF CAMBER ON REAR WHEEL KINETICS FOR MWC SPORTS

FRITSCH, C., ALTAMIRANO, A., BASCOU, J., THOREUX, P., SAURET, C.

INSTITUTION NATIONALE DES INVALIDES - ARTS ET MÉTIERS INSTITUTE OF TECHNOLOGY

INTRODUCTION: Manual wheelchair (MWC) sports require athletes to apply strong repetitive forces on the handrims to accelerate, turn or stop. For many MWC sports, manoeuvrability is critical to performance and, to this extent, the MWC configuration is usually modified by adding camber to the rear wheels. However, rolling resistance was observed to increase with camber (1). Besides, if the interest of camber on shoulder load was already shown, questions remain on the resulting power output at the wheel. This study aims to evaluate the maximum power produced by the user during propulsion for two MWC configurations, with and without camber, using a wheelchair ergometer.

METHODS: Five able-bodied participants were tested on a fully adjustable wheelchair ergometer equipped with 6-axis sensors on the handrims and velocity-controlled wheels. Seat height and fore-aft position were set as recommended for each subject (2,3). Camber angle was tested at 0 and 15° while keeping the other configuration parameters - and thus the joint configuration with the hand at the top dead centre of the handrim - strictly identical between the two configurations. For each configuration, participants were asked to apply maximum force on the handrims (x5) while wheels were turning at equivalent linear velocities of the MWC of 0.15, 1.0, 1.5 and 2.75 m/s, performed in a randomized order. The maximal propulsive moment was identified for each velocity in each configuration, and a linear regression was performed to identify the moment-velocity profile (4). Finally, the maximal theoretical power was derived from the power-velocity profile for each participant in each configuration (4). Results were compared between configurations with a Wilcoxon signed rank test.

RESULTS: Maximal propulsive moment was higher for all tested velocities in the configuration with camber (from 39.3±11.1 N.m at 0.15 m/s to 12.2±2.7 N.m at 2.75 m/s) than without (from 38.0±13.3 N.m at 0.15 m/s to 10.5±2.3 N.m at 2.75 m/s) but with no significative difference between the two ($p>0.1$). The maximal theoretical power was different between configurations (160.6±8.6 W with camber, 142.8±23.3 W without) with a 10% significance level ($p=0.06$).

CONCLUSION: Despite a higher rolling resistance with increasing camber, power output seems to be greater with camber than without. Indeed, the significance level of the difference in maximal power between configurations is above but close to 5%, which could be due to the small number of participants. Therefore, performance should not be impacted by adding camber to the wheels, especially linear acceleration. Moreover, these first results have proven the feasibility of testing and evaluating different configurations in similar velocity conditions, which could lead in the future to further tests with more modifications on the configuration and more velocity conditions.

OP-AP01 Training and Testing: Running

SAME-DAY RECOVERY FOLLOWING MODERATE INTENSITY EXERCISE IS NOT IMPACTED BY HOT- OR COLD-WATER IMMERSION POST EXERCISE IN TRAINED RUNNERS

MENZIES, C.

COVENTRY UNIVERSITY

INTRODUCTION: Post-exercise body temperature manipulation is a popular recovery strategy [1, 2], with both heating and cooling suggested to enhance recovery through alterations in tissue temperature and blood flow [3, 4]. However, post-exercise sauna-bathing has been shown to decrease next day performance [5], with biomarkers associated with fatigue (e.g. Interleukin-6 (IL-6), cortisol) increasing following passive heating [6, 7]. Therefore, this study aimed to assess same-day recovery following post-exercise hot (HWI) or cold (CWI) water immersion.

METHODS: Trained runners (n = 14. 11 males, VO2max: 3.4 ± 0.6 L/min) performed three trials consisting of two 45-min moderate intensity treadmill runs (Run 1, Run 2) separated by six hours. Following each Run 1, participants completed HWI (30 min, 40 °C), CWI (15 min, 14 °C), or control (CON; ambient rest) in a randomised order. Perceived effort and recovery were measured using Ratings of Perceived Exertion (RPE) and the Acute Recovery and Stress Scale (ARSS). Venous concentrations of adrenaline, noradrenaline, cortisol, IL-6, and its soluble receptor were measured. Femoral blood flow and rectal temperature were measured after the intervention following Run 1. Main effects were determined using linear

mixed-effects modelling with significance set as $p < 0.05$, with effect sizes compared to CON calculated as the mean difference divided by the square root of the sum of the random variance.

RESULTS: There was no difference between conditions in perceptions of recovery, as measured by RPE, during Run 2 (12 ± 2 AU, $p = 0.68$. HWI: $d = 0.1$, CWI: $d = 0.2$) or any of the ARSS subscales ($p > 0.05$), despite a significant effect of time for overall recovery, mental performance capacity, physical performance capability, and emotional balance ($p < 0.05$). Similarly, there was no effect of condition on any of the measured circulating biomarkers ($p > 0.05$). Adrenaline (0.3 ± 0.2 ng/mL) and noradrenaline (3.3 ± 1.4 ng/mL) peaked immediately post Run 1, whilst IL-6 peaked following the intervention period (2.1 ± 1.1 pg/mL). Femoral blood flow was significantly different between conditions post intervention ($p < 0.001$), being highest in the HWI condition (HWI: 661 ± 180 ml/min, $d = 4.5$, CWI: 67 ± 23 ml/min, $d = 1.1$. CON: 181 ± 56ml/min). Rectal temperature also differed between conditions post intervention ($p < 0.001$. HWI: 38.3 ± 0.4 °C, $d = 2.7$. CWI: 36.9 ± 0.3 °C, $d = 0.5$. CON: 37.1 ± 0.2 °C).

CONCLUSION: These data demonstrate limited effects of post-exercise HWI or CWI on perceptions of recovery and associated biomarkers, despite large differences in femoral blood flow and rectal temperature. Further work is required to investigate the effects of repeated post-exercise temperature manipulation on recovery, fatigue, adaptation, and improvements in performance.

STRENGTH TRAINING IMPROVES TIME TO EXHAUSTION SUBSEQUENT TO A PROLONGED RUN IN WELL-TRAINED MALE ENDURANCE RUNNERS: A RANDOMISED CONTROL TRIAL

ZANINI, M.1, FOLLAND, J.P.1, BLAGROVE, R.C.1

1. LOUGHBOROUGH UNIVERSITY

INTRODUCTION: Strength training has been shown to improve time trial performance and running economy (RE) when unfatigued in endurance runners (1). However, RE increases as runners fatigue (2) and consequently, the ability to produce high-intensity efforts, that often determines a race outcome, is reduced. Whether strength training improves RE over a strenuous prolonged run and alters the capacity to produce a high-intensity effort at the end of it, has not been investigated. This study aimed to examine the effect of strength training on the energy cost of running over 90 min and subsequent time to exhaustion (TTE) at a high-intensity in endurance runners.

METHODS: Thirty-eight well-trained male endurance runners (maximal oxygen uptake (VO2max) 58.6±7.0 ml/kg/min) were performance-matched and randomly assigned to a control (CG) and a strength training group (SG). The CG continued their regular training, while the SG added maximal strength and plyometric training twice weekly for 10 weeks. Before the training, participants completed an incremental test to determine lactate threshold 1 and 2 (LT1 and LT2) and VO2max, and on a separate day a 90min run at 10% delta between LT1 and LT2 (13.1±1.5 km/h, 80.7±4.0% VO2max). RE quantified as energy cost and rate of perceived exertion (RPE) were recorded at 15, 60, 75, and 90 min during the run. Following the 90 min run, participants completed a TTE run at 95% VO2max (16.1±1.6 km/h). A two-way repeated measures ANOVA with Bonferroni post-hoc correction was used to detect changes between groups, in TTE and pre-post delta in RE and RPE. Significance was defined as $p<0.05$ and effect size (ES) was calculated as partial-eta squared.

RESULTS: Twenty-eight subjects completed the study (14 SG, 14 CG). A significant and large group x time effect was detected for TTE ($p<0.01$, ES=0.48), with SG improving by 42±35% (251s vs 352s; $p<0.01$, ES=0.50), and CG worsening by 8±52% ($p>0.05$). There was a significant and large effect of trial time x group in RE ($p=0.04$, ES=0.21). Pre-post RE did not change between SG and CG at 15min, it was significantly better at 60 min (-0.2% vs 2.5%; $p=0.02$, ES=0.37), but not at 75 (-1.0% vs +2.2%; $p=0.06$, ES=0.26) or 90 min (-1.5% vs +2.1%; $p=0.10$, ES=0.21). Pre-post RPE was significantly lower in SG at 90min ($p=0.03$, ES=0.31), and decreased more (-7.8%, 15.8±2.0 vs 14.5±2.2) than CG (+5.8%, 16.6±1.6 vs 17.4±1.7) at the same time-point ($p=0.04$, ES=0.28).

CONCLUSION: Ten weeks of strength training in well-trained male endurance runners significantly improved TTE and reduced RPE following a prolonged run. RE changes between SG and CG were not different at 15, 75 and 90 min, but SG improved significantly at 60 min. These findings are in line with previous research on strength training in elite cyclists (3). Further research is warranted to clarify the adaptations to strength training contributing to TTE improvement and RPE reduction in a fatigued state.

THE EFFECT OF XC-RUNNING RACE LIDINGÖLOPPET ON RUNNING ECONOMY AND DETERMINANTS OF PERFORMANCE

RAPP, E.1, SUNDQVIST, C.2, CARDINALE, D.1,2

1.SWEDISH SCHOOL OF SPORT AND HEALTH SCIENCES, STOCKHOLM, SWEDEN 2.ELITE PERFORMANCE CENTRE, BOSÖN, SWEDISH SPORTS CONFEDERATION, LIDINGÖ, SWEDEN

INTRODUCTION: Determinants of running performance on flat terrain are known to be; running economy (RE), maximal oxygen consumption (VO2max) and fractional utilization (FU) (1). Off-road running performance is seldom studied with varying results between studies (2). Furthermore there is not an agreement between studies on how RE is influenced by fatigue induced by off-road running events, some indicating increased cost of running (3) whereas some showing de-

creased cost of running (4). The aim of this study was therefore to investigate determinants of performance in a 30 km cross-country (XC) running race with 522 m elevation gain and to investigate how RE is affected by the race.

METHODS: Thirteen runners (age 35±4 yr; VO2max 62.3±5.8 ml/kg/min) performed three testing sessions: 1. Laboratory testing of oxygen cost of running (CrOx), respiratory exchange ratio (RER), substrate utilization (fat% and carb%) during 5-min treadmill running at 14km/h as well as measurements of estimated lactate threshold (θLT), respiratory compensation point (RCP), VO2max (ml/kg/min) and speed at VO2max (vVO2max) during a graded exercise test (GXT). 2. Measurement of body composition using dual-energy X-ray absorptiometry. 3. Performing the race followed directly by measurements measurement of CrOx, Cr, fat%, carb% and RER running at 14km/h for 5 min. Analysis of CrOx, Cr and RER were performed using the last minute in the 5-min submaximal segments. For changes between pre- and post-race students t.test was performed. Determinants of performance was investigated using Pearsons correlation between race time and pre-test variables and performing multiple linear regression with race time as dependant variable.

RESULTS: CrOx (201.6±13.8 vs 208.4±9.3 ml/kg/km, p=0.041) and fat% (29±12 vs 48±18 %, p<0.01) increased post-race whereas carb% (71±12 vs 53±18 %, p<0.01) and RER (0.85±0.05 vs 0.91±0.04, p<0.01) decreased. Variance in race performance was best explained (R2=0.813, adjusted R2=0.743) by RER, CrOx and ml/kg/min at θLT. Race performance was significantly correlated to RER (r=0.645, p=0.017), CrOx (r=0.682, p=0.01), vVO2max (r=-0.757, p=0.004), speed θLT (r=-0.777, p=0.003) , ml/kg/min at θLT (r=-0.593, p=0.042) and speed at RCP (r=-0.722, p=0.012). VO2max (r=-0.575, p=0.051), ml/kg/min at RCP (r=-0.5, p=0.118), body fat % (r=0.51, p=0.109) did not correlate significantly with performance.

CONCLUSION: RE, CrOx, together with FU, θLT and RCP, and RER are strong determinants of 30 km XC-running race performance as shown by their capability to explain variance in performance time and by the relationship between performance time and CrOx, Cr, θLT, RCP and RER. However, weak determinants were VO2max and body composition as neither did relate to performance. The increase in CrOx with race-induced fatigue showed changes in RE, likely explained by the increase in fat% and decrease in carb%.

"WHY I MONITOR": WORLD-CLASS ENDURANCE COACHES' PERSPECTIVES OF ATHLETE MONITORING

TIMMERMAN, W., STANLEY, M., ABBISS, C., LAWLER, N., RAYNOR, A.

EDITH COWAN UNIVERSITY

INTRODUCTION: Athlete monitoring literature tends to focus on the tools and techniques of data collection and analysis, however there is a current lack of understanding as to why coaches implement these tools in their coaching. Therefore, the purpose of this research project was to elicit insights into why world-class endurance coaches conduct athlete monitoring practices.

METHODS: A qualitative descriptive research design was employed, using semi-structured interviews (Sandelowski, 2010). Twelve male coaches across canoeing, road and track cycling, rowing, triathlon, and swimming from Australia, Canada, Italy, South Africa, Spain, the USA, and the UK with 16.8 ± 6.4 years of experience were recruited. Eligible participants coached at least one endurance athlete to a top-3 performance in Major Games, World Championship, or cycling Grand Tour. The interview transcripts were analysed inductively using the iterative process of reflexive thematic analysis (Braun & Clarke, 2022). Rigour has been addressed through prolonged engagement with the data, peer examination where co-authors acted as critical friends, dense descriptions of the participants and research methods, and a documented audit trail of the research decisions.

RESULTS: The analysis generated five themes "Athlete involvement", "Tracking progress", "Learning and understanding", "Decision making", and "Achieving athletic potential". Tracking athletes' progress provides information to improve the coaches' understanding of their athletes and lead to more informed and contextualised decisions. The coaches perceive that athlete monitoring improves their decision-making to drive and adjust the training program while reducing negative training consequences, such as injury or illness, which is expected to contribute to athletes achieving their potential. Athlete monitoring is also used as a strategy to keep the athletes more closely engaged with their training process.

CONCLUSION: The in-depth insights gained from this study indicate that athlete monitoring has various important roles for world-class endurance coaches. For sports scientists, understanding the various purposes and nuances of athlete monitoring can assist them in providing suitable information at the right time to the coach, thus impacting the decision process and athlete's performance. Future research can explore how world-class coaches use athlete monitoring information to make decisions to refine the training program for the individual athlete and assess the impact coach background, coach-athlete relationship, and athlete information availability and presentation have on coaches' decision-making process and outcomes.

SEX INFLUENCE ON MUSCLE INFLAMMATION AND FUNCTIONAL RECOVERY AFTER RUNNING-INDUCED MUSCLE DAMAGE

MACCHI, R.1,2, KUNIMASA, Y.3, CORCELLE, B.4, FAZZARI, C.1, POMPORTES, L.1, CHAVET, P.1, VERCRUYSSEN, F.5, BENDAHAN, D.6, NICOL, C.1

1 AIX-MARSEILLE UNIVERSITY; 2 INSEP; 3 NIIGATA UNIVERSITY; 4 UNIVERSITY OF CÔTE DAZUR; 5 UNIVERSITY OF TOULON; 6 CNRS

INTRODUCTION: The repeated ground impacts and stretches involved during the active braking phase of a prolonged running task can induce muscle damage [1]. The resulting inflammatory process leads to functional alterations that peak 1 to 2 days after the exercise. Based on the expected protective effects of oestrogen [2], previous studies have suggested that women would show lower muscle damage and functional decline than men after eccentric exercise. However, results after running exercise in humans are lacking. The purpose of this study was to quantify muscle oedema (based on the cross-sectional area (CSA)) resulting from a 20-km graded running race and to assess the potential relationships with functional and neural changes.

METHODS: Two experimental groups (13 women (28±6 yrs); 14 men (36±9 yrs)) performed the race. The testing protocol included one session before (PRE) and two after the race, either on days 1 or 2 (D1-2) and days 3 or 4 (D3-4). This study included a control group (11 healthy participants, 24±4 yrs) who did not take part in the race and who completed two sessions. CSA and EMG activity were measured in 10 lower-limb muscles. Two functional tests, a squat jump (SJ) and a drop jump (DJ), were performed on a sledge ergometer. A Bayesian multilevel modelling approach allowed to assess the probability (pd) that the changes in participant involved in the race were different from those in the control group. Correlations and a self-organizing map (SOM) were used to assess the relationships between structural, functional and neural changes.

RESULTS: Men ran faster than women (1:44±0:09 h vs. 1:58±0:15 h, $p<0.01$). Regardless of sex, VL, SM, GL and TA showed a CSA increase up to D3-4 (pd=0.99). The SM CSA increase was higher in women than in men at D3-4 (+5.7 %). SJ performance decreased up to D3-4 for both sexes (pd=1). DJ performance decreased for women at D1-2 only (βD1-2 = -4.6±1.1 %; pd=0.99), but for men until D3-4 (βD1-2 = -6.1±1.1 %; βD3-4 = -6.2±1.4 %, pd=1). At D1-2, the increased gastrocnemius CSA was associated with an increased braking force in women whereas men decreased their lower-limb stiffness. Other structural-functional relationships were not always intuitive, but the SOM analysis revealed the combined influence of neural adjustments that did not depend on sex.

CONCLUSION: As previously reported [3], functional recovery is both sex- and test-dependent, and lasts longer in men in the DJ test. However, challenging the protective oestrogen effect, women showed more signs of inflammation in the SM muscle. The correlations highlight that structural alterations do not induce similar functional changes as function of sex and even opposite behaviours in DJ. The SOM analysis illustrates the complexity of neural adjustments related to dynamic multi-joint tests under fatiguing conditions.

OP-PN02 Physiology: Fatigue

WHICH FEATURES INFLUENCE MENTAL FATIGUE RESISTANCE? A PRELIMINARY ANALYSIS USING PERFORMANCE DETERMINING FACTORS

HABAY, J., ARENALES ARAUZ, Y.L., PROOST, M., DE PAUW, K., MEEUSEN, R., PATTYN, N., VAN CUTSEM, J., ROELANDS, B.

VRIJE UNIVERSITEIT BRUSSEL , ROYAL MILITARY ACADEMY , RESEARCH FOUNDATION FLANDERS

INTRODUCTION: Mental fatigue (MF) is known to negatively impact physical and cognitive performance. These effects seem to diminish based on the training level of participants, essentially creating a resistance to MF. However, not only are results on this resistance inconsistent across studies, it is still unclear which features might be responsible for it. Therefore, the goal of the present experiment was to assess the influence of different performance defining features on the MF response.

METHODS: Forty nine participants (26 men; 23 women; age = 31± 9 y; BMI = 22.79 ± 2.36 kg/m2 ; VO2Max = 46.92 ± 8.03 ml/min/kg) were included in this randomized counterbalanced crossover trial. At familiarization, researchers assessed features of participants that determine both physical and cognitive performance: VO2max (maximal incremental exercise test), sport expertise (questionnaire), response inhibition (cognitive task) and mental toughness (questionnaire). During subsequent visits, participants were either subjected to a 45 min Stroop task or a documentary before performing a cognitive (i.e. Go-NoGo task) and physical (i.e. time trial) performance test. The subjective level of MF was determined via M-VAS.

RESULTS: Statistical analysis showed a significant increase over time in subjective MF in the intervention condition (F = 89.25; p < 0.001; effect size (ES) = 0.65) and a significant increase in the intervention compared to the control condition at relevant time points (after the Stroop task (MF = 65.6 ± 20.3; CON = 28.0 ± 20.5): t = 10,37; p < 0.001; ES = 1.48). This subjective increase in MF translated to a significant negative effect on almost all aspects of cognitive performance (Go reaction time (MF = 385.10 ± 32.78 ms; CON = 368.80 ± 33.90 ms): t = 5.42; p < 0.001; ES = 0.77; Go accuracy (MF = 98 ± 2%; CON = 99 ± 1%): t = -2.20; p = 0.032; ES = -0.32; NoGo accuracy (MF = 89 ± 1%; CON = 91 ± 1%): t = -1.27; p = 0.211; ES = -0.18). There was no significant effect of MF on the distance parameter of the time trial (MF = 12.07 ± 1.56 km; CON = 12.34 ± 1.42 km; t = -1.85; p = 0.071; ES = -0.27). A multiple regression analysis incorporating the mentioned variables provided no significant prediction of the difference in cognitive and physical performance between the intervention and control group. Adjusted R square values of the predictions ranged between 0 and 8%.

CONCLUSION: The present study confirms a negative effect of mental fatigue on cognitive performance, while a trend to significance was found for the effect on physical performance. However, the most novel finding of the trial is that different aspects that determine an individual's performance level did not significantly predict the response to mental fatigue. The present analysis therefore primarily shows that the interindividual differences in mental fatigue resistance in the general population are influenced by an abundance of unknown and, most of the times, neglected internal and external factors.

EFFECTS OF INSPIRATORY MUSCLE FATIGUE ON EXERCISE PERFORMANCE IN YOUNG AND MASTER ATHLETES

MONS, V., LAVIGNE, C., MESTE O., MAUROY, B., BLAIN, G.M.

UNIVERSITÉ CÔTE DAZUR

INTRODUCTION: An increase in ventilatory work and associated respiratory muscle fatigue can compromise exercise performance by reducing blood flow and accelerating the development of fatigue in working muscles. Old individuals have a greater work of breathing during exercise, mainly because of reduced lung elastic recoil and/or increased airway resistance, suggesting that aged athletes (i.e. master athletes) may be especially susceptible to locomotor muscle fatigue with the increase in respiratory muscle fatigue. We tested this hypothesis by modulating the level of inspiratory muscle fatigue prior to intense exercise in young and master endurance athletes.

METHODS: Eight young (YA; age, 26.3±4.2 years; VO2MAX, 65.8±4.8 mL.min-1.kg-1) and eight master (MA; age, 64.7±5.3 years; VO2MAX, 48.3±5.8 mL.min-1.kg-1) endurance athletes performed, on separate visits, on a cycle ergometer, 1 maximal and graded test and 2 constant workload tests at 90% of peak power output to the limit of tolerance following an inspiratory resistive breathing task at 60% (CWT60%) or at 2% (CWT2%) of maximal inspiratory pressure (PIMAX) determined at rest. CWT60% and CWT2% were performed until failure and for 10 minutes, respectively. During the last visit, participants reproduced CWT2% but exercise was stopped when the same amount of work than CWT60% was reached (CWT2% ISOWORK). Quadriceps fatigue was assessed via pre- to postexercise (15s to 15min recovery) changes in maximal voluntary isometric contraction (MViC) and potentiated twitch force evoked by single electrical stimulation of the femoral nerve (QTsingle). Inspiratory muscle fatigue was assessed via pre- to post resistive breathing task changes in PIMAX.

RESULTS: PIMAX significantly decreased after CWT60% (ΔCWT60% = -19.3±7.4 cmH2O, p=0.002) but not after CWT2% (ΔCWT2%= -5.1±7.4 cmH2O, p>0.05) indicating inspiratory muscles fatigue prior exercise in CWT60%. Time to exhaustion significantly decreased in CWT60% (YA: 6.4±3.2 min; MA: 4.9±3.2 min) compared to CWT2% (YA: 7.7±2.9 min; MA: 7.9±4.5 min). This reduction in performance was 2.5 times greater (p <0.05) in MA (-35.2±20.1%) vs. YA (-14.3±16.7%). Despite the difference in exercise performance, reduction in MViC and QTsingle were similar following CWT60% (MVC, YA: -14.8%, MA: -13.3%; QTsingle, YA: -30.1%, MA: -26.8%) and CWT2% (MVC, YA: -15.7%, MA: -12.5%; QTsingle, YA: -28.8%, MA: -25.9%). In contrast, fatigue was less following CWT2 ISOWORK (MVC, YA: -9.7%; MA: -9.2%; QTsingle, YA: -23.9%; MA: -22.2%).

CONCLUSION: These findings suggest that inspiratory muscle fatigue accelerates the development rather than accentuates the severity of locomotor muscle fatigue and impairs exercise performance in endurance trained men. Despite similar levels of locomotor muscle fatigue, exercise performance impairment was more pronounced in master than in young athletes. With aging, inspiratory muscle fatigue thus increases the rate of locomotor muscle fatigue development during exercise.

IMPACT OF SINGLE AND INTERMITTENT/PROLONGED HOT-WATER IMMERSIONS ON SKELETAL MUSCLE FORCE AND FATIGABILITY IN YOUNG MALES

CHAILLOU, T.1, TREIGYTE, V.2, EIMANTAS, N.2, VENCKUNAS, T.2, BRAZAITIS, M.2

1 SCHOOL OF HEALTH SCIENCES, ÖREBRO UNIVERSITY, ÖREBRO, SWEDEN; 2 LITHUANIAN SPORTS UNIVERSITY, KAUNAS, LITHUANIA

INTRODUCTION: Passive heating such as hot-water immersion (HWI) increases rectal (Tre) and muscle (Tmu) temperatures, which could affect central and peripheral factors associated with neuromuscular function, respectively. Although HWI may influence maximal voluntary force and voluntary activation, as well as involuntary force and fatigue resistance, it is unknown whether the duration of HWI could have an impact on muscle function. Therefore, the aim of this study was to investigate the effect of single and intermittent/prolonged HWI on muscle torque, voluntary activation, and muscle fatiguability during electrically induced contractions.

METHODS: Twelve active males (27.2 ± 6.6 years old) were recruited for this study, including 2 phases: the phase "single exposure", (single phase, SP), followed by the phase "intermittent/prolonged exposure" (intermittent/prolonged phase,

IPP). Each phase consisted of 2 conditions performed randomly: HWI (44.5 °C water bath up to the iliac crest) or control sitting (CON). HWI was either continuous for 45 min (SP-HWI) or intermittent/prolonged for 300 min (IPP-HWI: initial 45 min followed by 8 x 15 min). Tmu (3 cm depth), Trec and physiological strain index (PSI) were determined. Neuromuscular testing was performed at baseline (BL) and 60 min after BL during SP, and at BL, 60, 90, 150 and 300 min after BL during IPP. Quadriceps muscle was electrically stimulated during these tests to determine torques at low (20 Hz: P20) and high (100 Hz: P100) frequencies, and P20/P100 ratio. Maximal voluntary isometric torque of the knee extensors (MVIC) and central activation ratio (CAR) were also determined. A fatiguing protocol (100 x 250-ms test train stimulation at 100 Hz of the knee extensors) was performed after the last neuromuscular testing (i.e., after 60 min in SP, and after 300 min in IPP) and torque fatigue index was calculated.

RESULTS: Compared to BL, similar increases after SP-HWI and IPP-HWI were found for Trec, Tmu and PSI ($p<0.001$). P20 and P100 were not significantly affected by HWI, while P20/P100 was slightly lower after SP-HWI and IPP-HWI compared to CON conditions ($p<0.05$). The reduction of MVIC (compared to BL) was larger after IPP-HWI than SP-HWI (-37.4 ± 39.4 Nm vs. -3.0 ± 10.9 Nm, $p=0.01$), and the reduction of CAR (compared to BL) tended to be higher after IPP-HWI than SP-HWI ($p=0.08$). Torque fatigue index was higher in HWI than in CON conditions, irrespective of the duration of HWI (condition effect, $p=0.001$).

CONCLUSION: HWI does not affect involuntary force but elicits a shift towards a faster contractile profile (i.e., decreased P20/P100) independent of the duration of heating. A larger reduction of MVIC (compared to BL) is found after IPP-HWI than SP-HWI, despite similar increases in Trec, Tmu and PSI. This result might be partly explained by the larger reduction of voluntary activation (although not significant) found after IPP-HWI than SP-HWI. Finally, HWI increases muscle fatigability regardless of the duration of exposure.

EFFECTS OF REPEATED CRYOSTIMULATION ON SLEEP QUALITY OF ELITE SWIMMERS DURING AN INTENSE TRAINING PERIOD.

ARC-CHAGNAUD, C., DUGUÉ, B., PLA, R., BOUZIGON, R., BOSQUET, L., DUPUY, O.

LABORATOIRE MOVE

INTRODUCTION: Elite athletes and swimmers in particular are subject to intense training (IT) loads many times during their season. IT may lead to fatigue accumulation, and requires proper recovery to optimize physiological adaptations. Among the large variety of recovery techniques, cryostimulation appears as an effective tool triggering various beneficial physiological effects for athletes' recovery. This technique consists in a short exposure (3 min) to very cold air (-110°) and is recognized to induce an improvement of physical and psychological wellness, a decreased inflammatory response, an activation of the parasympathetic cardiac tone, as well as beneficial effects on sleep, one of the key components of recovery.

This study aimed to evaluate the effects of daily partial body cryostimulation (PBC) exposure on sleep and recovery, in elite swimmers undergoing an intense training (IT) period.

METHODS: Twenty three elite French swimmers (7 females ; 16 males) were involved in this controlled cross-over protocol. The experiment took place during two weeks of IT load. Each week (5 days and 5 nights) represented one of the two experimental conditions: CRYO or CONT. A daily PBC exposure of 3 min at -110° was conducted - or not - during 5 consecutive days after the evening training. During the experiment, perceived anxiety, tiredness and depression, sleep quality (via actimetry and cerebral recording), and nocturnal heart rate variability (HRV), were evaluated. Salivary collection also permitted the measurement of anti-inflammatory markers. Salivary melatonin and CRP were measured in specimen collected at 10 p.m. and 6 a.m., respectively.

RESULTS: Perceived anxiety, tiredness and depression were reduced after the CRYO week, concomitant with an improved mood profile. Recordings of cerebral activity during the night highlighted an increased slow wave sleep duration of the first sleep cycle, during the CRYO condition. The other sleep parameters including total sleep time, sleep latency, efficiency or movements during the night remained unchanged. Whatever the condition was, salivary melatonin concentrations were higher before the fifth night of the protocol, whereas the mean C-reactive protein concentrations were lower in the CRYO week compared to the CONT one. Moreover, sleep analysis differed between good and bad sleepers. Nocturnal LF/HF ratio was higher in bad sleepers compared to good sleepers, whatever the condition was, suggesting a lower parasympathetic activity in swimmers subjected to lower sleep quality.

CONCLUSION: Repeated cryostimulation exposures during one week of IT improved perceived wellness of elite swimmers. It reduced inflammation and modulated sleep architecture by increasing SWS duration. Nocturnal HRV exhibited distinct patterns among swimmers depending on their sleep quality.

EXPLORING THE NEUROPHYSIOLOGICAL IMPACT OF MENTAL FATIGUE ON STRENGTH ENDURANCE: UNCOVERING THE ROLE OF MOVEMENT-RELATED CORTICAL POTENTIALS

PROOST, M.1, HABAY, J.1,2,3, DE WACHTER, J.1, DE PAUW, K.1,4, MARUŠIC, U.5, MEEUSEN, R.1,4, DE BOCK, S.1,4, ROELANDS, B.1,4, VAN CUTSEM, J.1,2

1 VRIJE UNIVERSITEIT BRUSSEL, BELGIUM 2 ROYAL MILITARY ACADEMY, BELGIUM 3 RESEARCH FOUNDATION FLANDERS (FWO), BELGIUM 4 ALMA MATER EUROPAEA-ECM, SLOVENIA

INTRODUCTION: Mental fatigue has become a significant area of focus within sports science due to its potential to decrease cognitive and physical performance. This psychobiological state has been shown to reduce accuracy, increase response time, and impair several physical performances, primarily endurance performances such as running and cy-

cling, mostly by increasing the ratings of perceived effort (RPE) without affecting physiological measures. The processing of neural signals in the brain is affected by mental fatigue, potentially providing further clues to unravel the link between mental fatigue and RPE. This study aimed to investigate whether performing a submaximal endurance leg extension task in a mentally fatigued state would lead to higher RPE than in a non-mentally fatigued state, and if so, whether the central motor command would be increased and reflected as an increased movement-related cortical potential-amplitude measured with electroencephalography (EEG).

METHODS: Fourteen healthy subjects (age: 23 ± 2 y, 5 females, 9 males) came to our lab for one familiarization trial and two experimental trials in this randomized, blinded, cross-over study. Participants had to complete a submaximal leg extension task after a mentally fatiguing task (an individualized 60 minutes Stroop task) or control task (documentary). The leg extension task consisted of performing 100 extensions at 35% of their 1RM, during which multiple physiological (heart rate, EEG, RPE) and psychological measures (MF, cognitive load, motivation) were assessed. These variables were also assessed throughout the rest of the protocol.

RESULTS: The subjective level of mental fatigue, measured by the M-VAS, was significantly higher in the intervention trials (71.71 ± 17.65 after intervention) compared to the control trial (36.64 ± 16.57) ($p<0.001$). Behaviourally, a decrease in accuracy on the Flanker task was detected in the intervention trial (from 0.96 ± 0.03 to 0.94 ± 0.03) ($p<0.05$). During the leg extension task, RPE was slightly higher in the mental fatigue trial than in the control group. Preliminary results of the movement-related cortical potential show no significant differences in amplitudes between both conditions. However, there seem to be individual differences between participants.

CONCLUSION: These results imply that mental fatigue was successfully induced. Preliminary results show that, depending on the individual response to mental fatigue, the amplitude of the movement-related cortical potential might be affected where the first analyses show an elevated or non-affected amplitude. This would support the hypothesis that mental fatigue plays a role in the processing of neural signals in the brain and, as such, affects the performance of an athlete. Further research regarding the individual response to mental fatigue while measuring brain activity is required.

OP-BM15 Neuromuscular Physiology: Central and/or spinal drive I

IPSI- AND CONTRALATERAL EFFECTS OF AN ACUTE BOUT OF LOCAL TENDON VIBRATION ON BILATERAL H-REFLEX EXCITABILITY

LAUBER, B., TAUBE, W., GOLLHOFER, A.
UNIVERSITY OF FRIBOURG

INTRODUCTION: Vibration via external devices has been frequently used as a training modality for improving athletes' performance and in rehabilitation. Tools providing local vibration (LV) have seen a recent trend in recreational use and physiological and clinical research identifying potential applications. The acute effects of a unilaterally LV on spinal excitability assessed by H-reflexes have only been investigated in the ipsilateral limb. However, there is evidence suggesting a bilateral change in performance after unilateral LV. Thus, it is important to understand the neurophysiology behind bilateral effects of unilateral LV.

METHODS: In 14 subjects (30 ± 5y, 7 females), bilateral soleus H-reflex excitability was tested before and after 20min of unilateral Achilles tendon LV at 45Hz. Initially, an H/M recruitment curve was measured followed by two baseline H-reflex measurements. Before the first H-reflex test, H-reflex amplitude was adjusted to 20% of Mmax. Then, 20 H-reflexes were applied. This was followed by 20min unilateral Achilles tendon vibration to either the left or right leg. Immediately after (0min), 5min, 10min and 15min, H-reflex recordings were repeated in both legs in a counterbalanced order. For analyses, peak to peak H-reflex amplitudes were normalized to Mmax and a repeated measures Anova was performed.

RESULTS: The results show that unilateral Achilles tendon vibration causes a significant suppression of the ipsilateral H-reflexes ($p < 0.0001$). Post-hoc test showed that H-reflex were significantly suppressed at 0min ($p = 0.0004$), 5min ($p = 0.0006$), 10min ($p = 0.0007$) as well as 15min ($p = 0.0009$). For the contralateral side, H-reflexes were significantly reduced ($p = 0.0002$), too. Post-hoc tests showed that H-reflexes were significantly suppressed at 0min ($p = 0.03$), 5min ($p = 0.03$), 10min ($p = 0.01$) as well as 15min ($p = 0.008$).

CONCLUSION: The present study shows that 20min of local unilateral Achilles tendon vibration resulted in a significant reduction of the H-reflex not only in the vibrated ipsilateral, but also the non-vibrated contralateral limb. Even though speculative, the reduced H-reflexes in both limbs might be caused by an increase in bilateral inhibition either caused at the spinal or supraspinal level. For the first time, we have shown immediate bilateral neurophysiological adaptations to LV. These bilateral neural adaptations may be – at least partly – be responsible for the bilateral changes in performance after unilateral LV.

IMPAIRED NEUROMUSCULAR JUNCTION TRANSMISSION AND MOTOR UNITS LOSS PRECEDE SARCOPENIA AND CONTRIBUTE TO THE LOSS OF MUSCLE FUNCTION IN OLD AGE

SARTO, F., PAGANINI, M., VALLI, G., SIRAGO, G., MORO, T., GOLDIN, E., PAOLI, A., DE VITO, G., STASHUK, D., FRANCHI, M.V., NARICI, M.V.

UNIVERSITY OF PADOVA

INTRODUCTION: Mounting evidence suggests that motoneuron and neuromuscular junction (NMJ) degeneration and motor units (MUs) loss contribute to muscle wasting and weakness in old age. However, these aspects are still poorly investigated in humans. This study aimed at comparing the neuromuscular system integrity and function across different stages of sarcopenia, with particular focus on NMJ and MU potential (MUP) characteristics.

METHODS: We recruited 42 healthy young individuals (YI) (aged 25.8±4.6 yr; 57% females) and 88 older individuals (aged 75.9±4.7 yr; 55% females). The older group underwent a sarcopenia screening according to the revised guidelines of the European Working Group on Sarcopenia in Older People (EWGSOP2), including the handgrip test, the Short Physical Performance Battery (SPPB) and a whole-body dual-energy X-ray absorptiometry (DEXA) scan. In all groups, knee extensors muscle force was evaluated by isometric dynamometry, muscle contractile properties by femoral nerve stimulation, morphology by ultrasound and MUP properties by intramuscular electromyography (iEMG). Motor unit number estimate (iMUNE) was also obtained.

RESULTS: From these evaluations, 39 older individuals were classified as non-sarcopenic, 31 as pre-sarcopenic and 18 as sarcopenic (SAR). Progressive reductions in whole quadriceps cross-sectional area ($p<0.001$) and appendicular lean mass ($p<0.001$) were observed across the different stages of sarcopenia. The three groups of older adults showed alterations in muscle architecture when compared to YI, evident as smaller vastus lateralis pennation angle ($p<0.001$) and increased ultrasound sarcopenia index ($p<0.001$). As expected, knee extensors force ($p<0.001$), handgrip force ($p<0.001$), chair-to-stand power ($p<0.001$) and SPPB score ($p=0.01$) were also progressively impaired. Muscle twitch peak tension was significantly reduced ($p<0.001$) in the older populations, as well as an increased half relaxation time (+19%, $p=0.049$) in SAR vs YI. Investigating potential neuromuscular mechanisms underpinning these alterations in muscle function and physical performance, we observed decreased NMJ transmission in older groups compared to YI, as suggested by elevated near fibre segment jitter ($p<0.001$). Interestingly, iEMG analysis revealed also reduced MU firing rates in SAR vs YI (-15%, $p=0.009$). The iMUNE was significantly lower ($p<0.001$) in the older groups, highlighting an age-related MUs loss.

CONCLUSION: We posit that impaired NMJ transmission and MUs loss likely contribute to the marked loss of muscle function in old age and that these alterations precede sarcopenia. The reduced MU firing rates in sarcopenic individuals may represent an adjustment to match the change in muscle mechanical properties (i.e. increased relaxation time), causing a left shift of the force-frequency curve, partly mitigating the force loss.

ON THE MODULATION OF HOFFMANN'S REFLEX FROM SEATED TO UPRIGHT STANDING ACROSS LIFESPAN

THEODOSIADOU, A.1, FABRE, M.2, PAPAVASILEIOU, A.3, SAHINIS, C.3, LAPOLE, T.2, PATIKAS, D.A.3, AMIRIDIS, I.3, BAUDRY, S.1

1.UNIVERSITÉ LIBRE DE BRUXELLES, LABNEURO, BRUSSELS, 2.UNIVERSITÉ SAVOIE MONT-BLANC, LIBM, SAINT-ETIENNE, 3.ARISTOTLE UNIVERSITY OF THESSALONIKI, SERRES, GREECE

INTRODUCTION: Upright standing involves specific neural modulation, which may be manifested by a decrease in the amplitude of the Hoffmann's reflex (H reflex) in the soleus muscle during upright compared with seated position (1,2). A greater decrease in H-reflex amplitude in upright standing was observed in old compared with young people, suggesting an age-related reorganization of postural control with a decrease reliance on proprioceptive inputs in favor of visual inputs and greater leg muscle coactivation (3). However, other factors could contribute to such a modulation as maximal plantar flexion strength and physical activity level. The aim of this work was therefore to investigate the posture-related modulation of H reflex across lifespan by a multiple regression analysis including physiological and behavioral factors.

METHODS: Fifty-one participants aged from 21-86 yrs stood upright with eyes open (EO) and closed (EC) on a force platform to measure the path length of the center of pressure (CoP). The soleus H-reflex was recorded in seated (H-seat) and upright (H-stand) posture. The contribution of visual inputs in postural control was assessed by the ratio EC/EO. Local vibration (Vib, 60 Hz) was also applied on the Achilles tendons with eyes closed to assess the contribution of proprioceptive inputs in postural control through the ratio Vib/EC. Multiple regression analysis was conducted with EC/EO ratio, Vib/EC ratio, EO, age, maximal plantar flexion force, ankle plantar flexors/dorsiflexors electromyographic ratio and the level of physical activity as independent variables, and H-stand/H-seat ratio as the dependent variable.

RESULTS: The fitted regression model was: H-stand/H-seat = 0.1+(-.143* Vib/EC) + (.712* EC/EO) +(.001*EO). The overall regression was statistically significant [$R2 = 0.37$, $F(3, 42) = 9.7$, $p<0.001$]. It was found that EC/EO ratio ($\beta = 0.49$, $p<0.001$) and EO ($\beta = 0.39$, $p = 0.007$) significantly predicted H-stand/H-seat ratio, while Vib/EC did not ($\beta = -0.28$, $p = 0.06$).

CONCLUSION: The results suggest that H-stand/H-seat modulation could reflect the central processing of the proprioceptive signal during upright standing by a lower ratio associated with greater processing of proprioceptive signal. Importantly, the data highlight that age may not be the primary driver of H-stand/H-seat modulation.

RETICULOSPINAL TRACT FUNCTION IN TRAINED AND UNTRAINED INDIVIDUALS; A CROSS-SECTIONAL ANALYSIS

ATKINSON, E., GOODALL, S., HOWATSON, G., ANSDELL, P., ŠKARABOT, J., THOMAS, K.

NORTHUMBRIA UNIVERSITY

INTRODUCTION: Non-human primate research has highlighted the reticulospinal tract (RST) as a likely site of adaptation following resistance training (Glover & Baker, 2020), however, such observations have yet to be demonstrated in humans.

METHODS: This study examined differences in human RST function between untrained and resistance trained individuals.

Methods. Fourteen resistance trained (age: 26 ± 5 years, training age: 5 ± 3 years) and eleven untrained (age: 27 ± 5 years) males and females were recruited. RST function was indirectly inferred from responses to cervico-medullary stimulations (CMEPp) and transcranial magnetic stimulations (MEPp), paired with a conditioning startling auditory stimulation of ≥ 110 dB, either 80 ms (CMEPp) or 50 ms (MEPp) apart (Furubayashi et al., 2000). The conditioned responses were expressed as a percentage of the unconditioned response. Following a maximal voluntary contraction (MVC) of their biceps (trained vs untrained: 304 ± 40 N vs, 254 ± 56 N; p = 0.016) and triceps (251 ± 37 N vs. 209 ± 40 N; p = 0.012) muscles, evoked responses were recorded at 20% of MVC with surface electromyography. The StartReact protocol, which assesses reaction times in response to visual (VRT), auditory (ART), and startling auditory stimuli (SRT), was employed for both muscle groups (Baker & Perez, 2017). RST gain, an index of RST function, was quantified as the difference in VRT and SRT with respect to the difference in VRT and ART.

RESULTS: No differences were found in the degree of the biceps CMEPp facilitation (162 ± 27 vs. 147 ± 23 %; p = 0.317) or MEPp inhibition (77 ± 14 vs. 75 ± 17 %; p = 0.692). Similar results were also seen in the triceps for both CMEPp (249 ± 76 vs. 211 ± 24 %; p = 0.291) and TMSp (79 ± 12 vs. 82 ± 17 %; p = 0.669) responses. For StartReact, trained participants had a faster bicep reaction time during the auditory condition (128 ± 24 vs. 150 ± 21 ms; p = 0.029), but no differences were observed in the triceps (131 ± 26 vs. 149 ± 29 ms; p = 0.106). For the startle condition there was a faster reaction time in the triceps of trained participants (104 ± 20 vs. 124 ± 22 ms; p = 0.031), but not biceps (104 ± 16 vs. 117 ± 18 ms; p = 0.066). VRT, RST gain, and startle-auditory reaction time were similar between trained and untrained groups for both muscles (p range from 0.09 to 0.89).

CONCLUSION: Resistance trained individuals displayed faster reaction times to a startling auditory stimulus, but the absence of difference between the majority of the outcome measures studied suggest RST function is similar in untrained, and chronically resistance trained individuals.

ACUTE CONTRALATERAL EFFECTS OF ECCENTRIC AND CONCENTRIC RESISTANCE EXERCISE ON THE NEUROMUSCULAR FUNCTION OF THE ELBOW FLEXORS IN HEALTHY INDIVIDUALS

VALDÉS, O., REHBEIN, C., NÚÑEZ, O., CHALCHAT, E., SIRACUSA, J., GARCÍA-VINCENCIO, S., THOMAS-JUNIUS, C., CHENNAQUI, M., MARTIN, V., PEÑAILILLO, L.

UNIVERSIDAD ANDRÉS BELLO

INTRODUCTION: Contralateral concentric and eccentric resistance training have shown differential limb-to-limb cross-transference of muscle strength and corticospinal excitability in the non-trained homologous muscle. However, the underpinning mechanisms of the transference of force-related outcomes are unclear. It is possible that acute contralateral neuromuscular responses following concentric (CONC) and eccentric (ECC) resistance exercise bout could be differently modulated at corticospinal and muscular levels. We compared the acute effects on the neuromuscular function at corticospinal and muscular levels of the non-exercised contralateral elbow flexor muscles after a CONC and ECC resistance exercise bout.

METHODS: 30 healthy young men (CONC=24.3 years; ECC=25.5 years) were randomly allocated into CONC (n=15) or ECC (n=15) groups. Both groups performed a control (CTRL) session condition one week prior to the experimental intervention to determine the reliability of measurements and to determine the changes in ECC and CONC in relationship to CTRL in all dependent variables. The resistance exercise consisted of one bout of five sets of 10 repetitions at 80% of the concentric or eccentric 1-Repetition Maximum. Biceps brachii (BB) muscle surface electromyogram (EMGRMS) was recorded during training. Maximal voluntary isometric contraction (MVIC) torque and EMGRMS of BB muscle from the non-exercised and exercised arm were assessed before and after training. Peripheral nerve stimulation (PNS) and single-pulse transcranial magnetic stimulation (TMS) mechanical (i.e., torque) and electrical responses (i.e., EMG) were measured in the non-

exercised elbow flexor muscles. All measurements were taken before and 30 min after in CTRL, and before and immediately after CONC and ECC. Furthermore, the NASA-TLX questionnaire was applied after CONC and ECC to assess the mental-physical demand of the exercise. Two-way repeated measures analysis of variance (RM-ANOVA) was used to compare groups and times.

RESULTS: The reliability for all dependent variables were good to excellent (ICC=0.75-≥0.90). All variables remained unchanged in CTRL, CONC, and ECC conditions (group x time effect; P>0.05). ECC showed a greater total training volume than CONC (20.7%, P=0.01). CONC and ECC decreased the elbow flexors MVIC torque (-21.7%, P<0.001; -34.29%, P<0.001, respectively) and BB EMGRMS (-20.1%, P<0.001; -13.8%, P<0.001, respectively) after exercise, similarly (P=0.06 and P=0.84, respectively). Both groups evoked similar (P=0.17) BB EMGRMS activity in the contralateral no-exercised arm during training and imposed similar (P=0.81) mental-physical demands after exercise. No group x time effect (P>0.05) was found between CONC and ECC for MVIC, BB EMGRMS, PNS, and TMS mechanical and electrical responses after exercise.

CONCLUSION: We suggest that acute corticospinal excitability after a single bout of unilateral resistance exercise is not related to contralateral adaptions shown following CONC and ECC training.

OP-AP20 Racket Sports: Training and Testing

IMPACT OF SPRINT MECHANICAL PARAMETERS ON ELITE JUNIOR TENNIS PERFORMANCE

VOLK, N.R., VUONG, J.L., FERRAUTI, A.

RUHR UNIVERSITY BOCHUM

INTRODUCTION: Movement speed is considered essential for success in many team and racket sports. However, only split times have been used, compromising information about how two players might achieve a given split time during a linear sprint (LS). Therefore, this study aimed to correlate sprint mechanical parameters (SMP) of a 20m LS test obtained with a motorized resistance device (MRD) to the current gender-specific tennis ranking position in tennis (RP).

METHODS: 107 male and 86 female elite junior tennis players nationally ranked in the German Tennis Federation between 10 and 18 years participated in the study. The players original rankings on the overall list were revised so that the top-ranked player was placed first and the lowest-ranked player last. According to their age at peak height velocity (PHV), players were divided into pre-PHV, circa-PHV, and post-PHV groups. Players performed two maximal 20m sprints on an indoor tennis hard court. SMP, like maximal theoretical force (F0; N/kg), and maximal theoretical velocity (v0; m/s), maximal power (Pmax; W/kg), were derived from instantaneous time-velocity data measured with 333Hz. SMP of the LS were partially correlated with the current RP in the overall national ranking by controlling for biological maturation.

RESULTS: Low to moderate correlations (rs=-0.1 – -0.3) were found between SMP and the RP in all male and female age groups. However, separated by gender, low significant correlations between SMP and RP were found in females (rsv0 = -0.33; rsPmax = -0.31; rsRFmax = -0.22), whereas none were found in males. All linear SMP improved over maturation for both genders. After the PHV, F0 values improve to a lesser amount compared to v0. Regarding sprinting performance, Pmax showed the highest correlation of all SMP to 20m split time in both males (r=-0.77) and females (r=-0.86). Additionally, the correlations of F0 are the strongest for short distances, while correlation values for v0 increase for longer sprint distances.

CONCLUSION: Sprint mechanical parameters have overall a low to moderate relevance for tennis performance which can be explained by the dimensions and high demands of technical and tactical skills. The importance of LS seems to be more pronounced in girls compared to males, most likely due to different playing styles. The relevance of physical attributes might hence be elevated in female junior tennis. Male and female players develop a more velocity-oriented F-v-Profile over maturation, which is mainly responsible for the increase in Pmax. Since improvements of F0 are diminished compared to v0, especially after PHV, training should be tailored to the development of force production at low velocities. It is reasonable to assume that such training emphasis could further increase performance given the usually short distances during match play.

DEVELOPMENT OF UPPER AND LOWER EXTREMITY FUNCTIONAL ASYMMETRIES IN MALE AND FEMALE ELITE YOUTH TENNIS PLAYERS: A LONGITUDINAL STUDY

CHAPELLE, L.1, D'HONDT, J.1, BISHOP, D.2, ROMMERS, N.1, D'HONDT, E.1, CLARYS, P.1

1 DEPARTMENT OF MOVEMENT AND SPORT SCIENCES, VRIJE UNIVERSITEIT BRUSSEL; 2 LONDON SPORT INSTITUTE, MIDDLESEX UNIVERSITY

INTRODUCTION: Functional asymmetries are defined as side-to-side differences in physical performance (e.g., regarding strength, power and agility) between both upper or lower extremities. Although every individual naturally develops a certain magnitude of functional asymmetry, systematically performing a predominantly unilateral sport (i.e., such as tennis) may increase the already present inter-limb differences. Previous research has shown that functional asymmetries have been reported to increase injury risk whilst decreasing sports performance. Nevertheless, longitudinal studies examining how the magnitude of functional asymmetry and its consistency in directionality develops according to chronological

age are currently lacking. Therefore, this three-year longitudinal study aimed to examine the development of upper and lower extremity functional performance values, together with asymmetry magnitudes and directionality.

METHODS: Dominant (i.e., the best overall result of a performance test independent of extremity) and non-dominant physical performance values (i.e., the best result of the same performance test of the same extremity on the other body side) were determined yearly (i.e., and up to 3 years) using unilateral strength, power, speed and agility tests in 53 male and 37 female elite youth tennis players aged 8 - 17 years. For each test occasion, functional asymmetry magnitude percentages were calculated using the percentage difference method. Using R version 4.2.2, linear mixed effect models examined the development of performance values according to chronological age, performance dominance and sex. Similarly, the development of functional asymmetry magnitudes was examined according to players' chronological age and sex. Kappa coefficients (k) examined the consistency in directionality (i.e., which extremity performed dominantly across test occasions).

RESULTS: Regardless of sex, the dominant and non-dominant performance values of every test significantly ($p < 0.05$) improved according to chronological age. No sex differences were apparent except for strength and power related tests, with male players performing significantly better compared to female players. Functional asymmetry magnitudes ranged from 2.5 % to 14.6 % and did not significantly change with increasing chronological age (i.e., range = -0.3 % to 0.2 % per year). The dominant upper extremity (i.e., which holds the racket) consistently displayed the dominant performance value (i.e., k-value = 1.00) across test occasions, which was not the case for the lower extremity (i.e., k-value range = -0.28 to 0.31).

CONCLUSION: The functional asymmetry magnitudes, showing a high amount of direction-specificity and variation in individual developmental patterns, did not change significantly according to chronological age over a 3-year period. It is, therefore, uncertain whether aiming for a reduction in asymmetry magnitude is favourable.

APPLICATION OF VIDEO ANALYSIS TO THE MEASUREMENT OF REACTION TIME IN HIGH-LEVEL TENNIS COMPETITION

ANNINO, G., BONAIUTO, V., CAMPOLI, F., CAPRIOLI, L., EDRISS, S., PADUA, E., PANICHI, E., ROMAGNOLI, C.

TOR VERGATA UNIVERSITY OF ROME

INTRODUCTION: 2D Video analysis is often used in tennis to analyze the technique of players movements or issues related to game tactics. In modern tennis, many physical and mental abilities are involved in the performance of high-level athletes, who are called upon to solve complex motor problems in a short time through sprints and explosive actions often performed in precarious balance[1]. Indeed, by the tennis players performance model, it appears as various coordinative and perceptive kinetic abilities, such as reaction, anticipation, and transformation, play a fundamental role[2][3]. In this paper is applied video analysis to measure and evaluate the reaction time (RT) in tennis matches. The data shows the RT analysis of some professional players made during the ATP Challenger "Castel del Monte" tournament in November 2022.

METHODS: The analysis was carried out using the software BIOMOVIE ERGO on video 240 Hz, filmed by a WOLFGANG Action Camera placed behind the center court. For the measurement of RT, the time between the impact of the opposing player and the first movement of the examined player was measured (the first movement coincides with the rotation of the shoulder line in the direction of movement or of the foot descending from the split-step or with a countermovement of the contralateral leg). Sixteen subjects were examined (25.88 ± 4.77 years old, weight 79.13 ± 5.67 kg, height 184.40 ± 5.30 cm, BMI 23.26 ± 1.19) all with an ATP ranking between the #130 position and the #1066 position updated on the day of the sampling.

RESULTS: The average reaction time was 0.249 ± 0.07 s, with a correlation to the level of play as tennis players with an ATP ranking between #130 and #400 had a mean RT of 0.246 ± 0.07 s, and subjects with a ranking between #400 and #1066 a mean RT of 0.251 ± 0.07 s. The longest reaction times were recorded on the first shot after the serve on average 0.282 ± 0.05 s, while the shortest in defensive situations when the opponent was attacking or playing a volley and the player examined anticipated the movement by starting the run even before the opponents shot sometimes. The average RT recorded in this case is 0.083 ± 0.18 s. In the service response phase, on the other hand, it approaches the general average value with 0.245 ± 0.03 s.

CONCLUSION: The RT of high-level tennis players are very short, sometimes less than 120 ms, especially in defensive actions when the player often starts before the opponents attacking stroke. This prompts us to consider the importance of kinetic perceptual skills such as reaction speed and anticipation in tennis training.

COMPARISON OF ANTHROPOMETRIC, PHYSICAL PERFORMANCE AND MOTOR ABILITY AMONG SELECTED AND NON-SELECTED JUNIOR BADMINTON PLAYER IN MALAYSIA.

TENGKU KAMALDEN, T.F., NORJALI WAZIR, M.R.W., PION, J.

UNVERSITI PUTRA MALAYSIA

INTRODUCTION: The purpose of this study is to determine the level of anthropometric, physical performance and motor ability among Malaysian junior badminton players. This study is a cross sectional study aiming at benchmarking the 30 best adolescent players in Malaysia.

METHODS: A sample of 135 Male players and 103 Female players between the age of 12 years to 14 years were measured with two anthropometric tests i.e., standing height and body weight. While the physical performance and motor ability tests consist of 18 tests (sit & reach, handgrip, shoulder rotation, sit up, knee push up, standing broad jump, counter movement jump, shuttle run, 30m sprint, beep test, jumping sideway, moving sideways, walking backward, eye hand coordination, shuttlecock throw and plate tapping). Data were analysed using descriptive analysis and Independent T-Test to define the differences between selected and non-selected players.

RESULTS: The findings of the study showed that there were significant differences in every age group and gender. Male players aged 12 years old showed significant differences in standing broad jump (p=0.01,t=-2.69), beep test (p=0.04,t=-2.06) and moving sideways (p=0.01,t=-3.02) between the selected and non-selected players, while only standing height show significant differences for 13 years old male players (p=0.03,t=2.13). There were significant differences among the 14 years old male players for sit up (p=0.01,t=-3.69), counter movement jump (p=0.02,t=0.21) and plate tapping (p=0.02,t=-2.56). Meanwhile, among the female players, the 12 years old show significant differences between the selected and non-selected in sit & reach (p=0.03,t=-2.16), shuttle run (p=0.01,t=4.24), standing broad jump (p=0.01,t=-4.27), moving sideways (p=0.01,t=-2.53), plate tapping (p=0.05,t=-2.03) and standing height (p=0.03,t=-2.16). As for the Female players aged 13 years old, significant differences were shown in shuttle run (p=0.01,t=2.75), sit up (p=0.01,t=-3.64) and standing height (p=0.04,t=-2.18). The female player age 14 years old showed significant differences in sit up (0.01,t=-4.91), eye hand coordination (p=0.04,t=-2.19), shuttle throw (p=0.01,t=3.07) and plate tapping (p=0.01,t=-4.27) between the selected and non-selected players.

CONCLUSION: This study attempted to explore the importance of anthropometric, physical performance and motor ability in the selection process for the Malaysian elite sport school. The results displayed the different profiles of young elite badminton players between age group and between gender regarding their performances.

IS-EX01 ACSM-ECSS exchange: Contemporary Approaches to Sport Injury Rehabilitation – "Imparting Creativity and Ingenuity to Push Against the Accepted Norms"

INJURY PREVENTION DOES NOT WORK

VERHAGEN, E.

VU UNIVERSITY MEDICAL CENTER

Although evidence suggests that sport and recreational physical activity has significant health benefits, associated injuries have substantial adverse short- and long-term side effects. With the current focus on increasing physical activity and sports, injuries will become an increasingly important contributor to ever-rising societal health care costs. Action, as such, is needed. The scientific literature contains a wealth of evidence on efficacious interventions to reduce the number and the direct and indirect burden of injuries. Evidence has been gathered for various injuries, employing different preventive measures, and across multiple sports. One would expect a reduction in the number of injuries based on this work. The opposite is true, however. An increase in the annual number of injuries is still seen over the last ten or so years. While this increase is in line with an increase in the number of active sports participants, the actual injury incidence rate - as a measure of injury risk - has also increased. The above highlights that we know less than we actually may believe. In this lecture I will explore the available preventive evidence and focus on the reach and breadth of what we actually know. I will link this to contemporary issues in sports injury prevention, and highlight potential future directions towards making significant impact by preventive injury in sports.

DE-ICED: WEANING SPORTS HEALTH CARE PROFESSIONALS OFF THEIR DEPENDENCY ON REST-ICE-COMPRESSION 2023 AND BEYOND!

KAMINSKI, T.

UNIVERSITY OF DELAWARE

The use of ICE has been a cornerstone in the treatment of athletic injuries for decades. Unfortunately, there is a lack of persuasive evidence to support its use. As we embark on a new decade and the practice of athletic training & sports health care continues to evolve, more and more clinicians (especially those in the younger generation) are beginning to question this long-standing treatment. In light of this, athletic trainers and other sports health care professionals need to gain a better understanding of the physiological effects of cryotherapy, especially in the acute setting, as well as establish

a better understanding for the importance of assisting the lymphatic system by enhancing the inflammatory response to injury. While some may consider such a topic counterintuitive to well-established clinical practice, the importance of beginning such dialogue and allowing for useful and productive dialogue is critical in moving the art and science of athletic training forward into the future.

OP-BM06 Balance and posture

SPORT DEPENDENT EFFECTS ON THE MULTISENSORY BALANCE INTEGRATION DURING UPRIGHT POSTURE: A COMPARISON BETWEEN PROFESSIONAL HORSEBACK RIDERS, JUDOKAS AND NON-ATHLETES.

VISEU, J., YIOU, E., MORIN, P.O., OLIVIER, A.

UNIVERSITÉ PARIS SACLAY

INTRODUCTION: It is well-known that postural stability is improved with intensive sport practice (1). The contribution of sensory inputs to balance control also changes, with athletes relying less on vision and more on somesthetic inputs than non-athletes (NA) (2). It is however noteworthy that, in the literature, balance performance and sensory processing are investigated in athletes practising a sport in the standing posture (e.g. judo, soccer etc.). The present study hypothesised that high-level (HL) athletes practicing a sport in the sitting posture (horseback riding) develop specific balance and sensory adaptations.

METHODS: Thirty-four HL judokas (JU), 27 HL horseback riders (HR) and 21 NA participated in the experiment. They stood upright on a stabilometric platform (static condition) or on a seesaw device with a mediolateral (ML) or anteroposterior (AP) instability (dynamic conditions). These stability conditions were carried out with eyes opened (EO) or closed (EC). Experimental variables included linear (mean center-of-pressure (CP) velocity (VCP), standard deviation of CP shift along ML (SDX) and AP (SDY) direction) and non-linear parameters (SampEnX and SampEnY, corresponding to ML and AP sample entropy, respectively; these variables reflect the attentional cost of balance, (3)).

RESULTS: VCP was significantly lower in both HL groups than in NA under all stability conditions ($p<0.05$), while SDY was lower in HR than in JU under static and AP dynamic condition ($p<0.01$). In EO, VCP was lower in HR than in both JU and NA under dynamic conditions ($p<0.001$). In EC, VCP was lower in JU than in HR and NA under dynamic conditions ($p<0.05$). Finally, SampEnX was higher in HR than in JU under static condition ($p<0.05$), while SampEnY was higher in HR than in JU under both static and ML dynamic condition ($p<0.01$).

CONCLUSION: As expected, JU and HR had a better stability than NA under all stability conditions. More originally, results showed that HR relied more on vision to control balance. In addition, entropy variables revealed that JU devoted more attention to control balance than HR. These results suggest that the sensory contribution and attentional cost of balance is sport-dependent, and may depend on the posture adopted by athletes during their practice. These results open up new knowledge on the specificity of balance control in sports and may be useful to select relevant stabilometric variables for the follow-up of HL athletes.

ASSESSMENT OF VISUAL SENSORY REWEIGHTING IN STANDING BALANCE USING VIRTUAL REALITY

ASSLÄNDER, L., ALBRECHT, M., MISSEN, K.J., CARPENTER, M.G., STREUBER, S., GRUBER, M.

UNIVERSITÄT KONSTANZ

INTRODUCTION: Sensory contributions to the control of human balance is of particular interest in sport-, clinical- and basic-science. Often, proxy measures, such as visual field dependence using the rod-and-frame test, or spontaneous sway measures in different stance conditions are used. None of these measures, however, represent a valid measure of sensory contributions in standing balance. For example, a sense of instability when closing the eyes can lead to co-contraction, which can reduce spontaneous sway amplitudes. At the same time, vestibular and proprioceptive contributions increase when closing the eyes, which changes overall sensory noise properties. These and more factors affect spontaneous sway. Therefore, it is not possible to make inferences on these different factors from spontaneous sway measures alone.

Reliable assessments of sensory contributions can be achieved by inducing controlled perturbations on one system, e.g. by moving the visual scene. As the scene is used as a sensory reference, its movement evokes sway. The sway amplitude depends on the stimulus amplitude and on the extent the visual system contributes to balance. Taking into account the feedback nature of the balance control mechanism, as well as basic assumptions on neural properties and biomechanics, the contribution of the visual system in a given situation can be validly assessed.

The methods are well described in the literature. However, the implementation is difficult due to the required equipment (motorized visual scene with high precision) and the required numerical methods.

METHODS: In this study, we tested, whether sway responses to moving scene perturbations realized using a virtual reality (VR) head-mounted display (HMD) are comparable to responses using a motorized real-world scene. Furthermore, we tested the feasibility of standardized implementations of a parameter estimation routine and the reliability of the obtained measures.

Body sway of fourteen subjects wearing a VR-HMD and VR motion trackers was measured, while moving a virtual screen which covered the subjects' field of view. The setup mimicked a published real-world experiment conducted by Peterka (2002), using 10x60.5-s long screen movement sequences.

RESULTS: We statistically compared our virtual to the published real-world results using statistical non-parametric mapping and found no significant differences. Test-retest reliability of single subject parameters was poor when using only 5 cycles of a 20-s pseudo-random sequence, but became excellent, when estimating parameters from 10-15 cycles (Intraclass correlations 0.7-0.9).

CONCLUSION: In conclusion, we showed that the visual contribution to standing balance can be reliably assessed using a VR-HMD. As VR systems have become widely available, future work will provide software solutions implementing experiments and analysis techniques for such advanced balance assessment techniques.

INTERACTION OF MOTOR AND COGNITIVE FUNCTIONS RELEVANT TO DUAL TASK COSTS ARE RELATED WITH AUTOMATICITY OF POSTURAL CONTROL

CESNAITIENE, V.J., PUKENAS, K., KUŠLEIKIENE, S., SHEORAN, S., DROZDOVA STATKEVICIENE, M., VINTS, W.A.J., MASIULIS, N., LEVIN, O.

LITHUANIAN SPORTS UNIVERSITY

INTRODUCTION: It is well known that motor and cognitive functions decline with age (1). Dual tasking can affect performance on one or both performance domains, but the opposite is also observed (2). For example, there are cases where the performance on a dual task balance test is unaffected but even improved (3) which may be explained by higher automaticity of balance control. Therefore this study aimed to investigate automaticity of balance control relations to dual-task costs of postural control.

METHODS: Sixty-seven males and females aged 60-80 years old participated in the study. To assess balance performance a posturography method with a single piezoelectric force plate was used to measure postural sway activity. Participants were tested barefoot in two stance conditions: double-stance with eyes open (STEO) and Tandem Romberg stance with eyes open (REO).

To estimate the dynamical characteristics of the posturogram, Center of pressure (CoP) velocity vector (Vcop) and wavelet entropy (WEcop) were calculated in both the anteroposterior (AP) and mediolateral (ML) directions. Dual task cost (DTC) was expressed as percentage of the differences in the two measures relative to their baseline single task measure. The test of repeated measures of the General Linear Model (GLM) was used to assess the condition effect (dual-task and baseline-task) on the balance performance. The correlations between DTC and both baseline entropy and baseline Vcop were calculated.

RESULTS: We found that higher values of baseline entropy (i.e., better equilibrium ratio) resulted in lower values of DTC in both stance conditions, expressed by positive significant correlations between DTC and baseline entropy in all sway directions: STEOML ($p<0.001$; PES=0.212; OP=0.980); STEOAP ($p<0.001$; PES=0.338; OP=1.000); REOML ($p<0.001$; PES=0.240; OP=0.988); REOAP ($p=0.002$; PES=0.152; OP=0.886). In contrast to entropy, baseline levels of Vcop had no significant effect on DTC (all $p > 0.05$).

CONCLUSION: Since the regularity of balance behavior is associated with the systems automatic control, it can be argued that better automatic control of balance results in less dual-task loss of postural control.

IMPROVED POSTURAL CONTROL IN THE ELDERLY AFTER BALANCE TRAINING IS RELATED TO A REDUCTION IN PREFRONTAL HEMODYNAMIC ACTIVITY

LEHMANN, N.1, KUHN, Y.A.2, KELLER, M.3, AYE, N.1, HEROLD, F.4, DRAGANSKI, B.5, TAUBE, W.2, TAUBERT, M.1

1 OTTO VON GUERICKE UNIVERSITY MAGDEBURG, 2 UNIVERSITY OF FRIBOURG, 3 UNIVERSITY OF BASEL, 4 UNIVERSITY OF POTSDAM, 5 LAUSANNE UNIVERSITY HOSPITAL AND UNIVERSITY OF LAUSANNE

INTRODUCTION: Aging-related deterioration of postural control is widely regarded as an important phenomenon influencing quality of life and longevity. It is thought that as we age more cortical involvement is required to cope with given task demands [1]. For example, it has been shown that the hemodynamic response of the prefrontal cortex (PFC) during balancing is higher in older compared to younger individuals. Furthermore, the fact that greater reliance on the PFC is related to poorer balance performance suggests that it is a dysfunctional phenomenon [2]. Therefore we hypothesize that

in older people, balance training (BT) may cause a shift in cortical hemodynamics towards a youth-like pattern, which in turn could be a mechanism underlying improved postural control.

METHODS: To test this hypothesis, we conducted a longitudinal, controlled trial with healthy older participants (age range 66-81y) to compare the effects of a 6–month BT intervention (n = 18; 1h of BT twice weekly) against a non-BT group (n = 15) on balance performance. Cortical hemodynamics during balancing on a wobble board was assessed using functional near-infrared spectroscopy (fNIRS) at four time points during the study: at baseline, after 2 (post1), 6 (post2) and 12 months (follow-up). fNIRS data were acquired using a stationary continuous-wave imaging system (NIRx Medical Technologies) and subsequently preprocessed with Homer [3].

RESULTS: Reproducibility of balancing-induced hemodynamic responses across three PFC subregions was sufficient (ICC's ≥ .50, p's ≤ .04). In terms of behavior, the BT group reduced the sway on the unstable device (center of pressure path) significantly more than controls (group*time interaction $p < .05$). Nonparametric combination analysis [4] revealed that at post2, the BT group showed a consistent reduction in cortical activity in three subregions of the PFC compared to the control group ($p < .05$). Furthermore, in two PFC subregions (middle and superior frontal gyri), training-related changes in balance performance at post1 and post2 were correlated with concurrent changes in cortical activity while balancing (repeated measures correlation [5]: r's ≥ .30, p's ≤ .01).

CONCLUSION: The present study suggests that the aging-related neural inefficiency of the PFC and associated declines in balance performance can be ameliorated by targeted balance training. Our results substantiate balance training as a behavioral countermeasure to aging-related decline in postural control [6] and demonstrate that fNIRS is sensitive to capture longitudinal changes in the cortical control of balance [7].

MOTOR CORTICAL CONTROL DURING DUAL-TASK PERFORMANCE

TOKUNO, C.1, WÄLCHLI, M.2, LAUBER, B.2, TAUBE, W.2

1 BROCK UNIVERSITY; 2 UNIVERSITY OF FRIBOURG

INTRODUCTION: Body instability increases when individuals dual-task (i.e., maintain balance while simultaneously performing a secondary task), with larger effects occurring during more challenging dual-task conditions. Although previous studies have examined the cortical mechanisms involved in balance control, these studies have largely been conducted with the individual performing only a balance task. Therefore, this study examined how the motor cortex is involved during dual-tasking and whether this control is dependent on the dual-task type (cognitive or motor secondary task) and the difficulty of the primary (balance) task.

METHODS: Thirty adults maintained their balance on a platform that rotated around the pitch axis with or without a concurrent secondary task. The balance task was performed at two resistance levels (easy and hard difficulty). The secondary task consisted of either a cognitive (2-back number recall) or a motor (balancing a ball on a hand-held tray) task. For each trial, participants received a series of single- (120% of active motor threshold; aMT) and paired-pulse (stimulus at 80% aMT followed by another at 120% aMT) transcranial magnetic stimuli over the motor cortical area representing the tibialis anterior.

RESULTS: Regardless of balance difficulty, dual-tasking with the motor task resulted in a 34±5% greater sway velocity than when balancing on its own ($p<0.001$). In contrast, dual-tasking with the cognitive task had the opposite effect. Compared to the balance-only condition, addition of the cognitive task improved balance performance by 11±5% when the balance task was easy ($p=0.014$), but elicited no change in performance when the balance task was hard. These dual-task effects were accompanied by neurophysiological changes. Corticospinal excitability (CSE), as measured by the single-pulse motor-evoked potentials (MEPs), was influenced by main effects of balance difficulty ($p<0.001$) and task ($p<0.001$). Not only were MEPs 34±8% larger when the balance task was made harder, MEPs were also larger when dual-tasking with the motor task (0.8±0.1 mV) compared to dual-tasking with the cognitive task (0.6±0.1 mV) and single-tasking with balance only (0.7±0.1 mV). Lastly, short interval intracortical inhibition (SICI), as measured by the paired-pulse MEPs, was influenced by main effects of balance difficulty ($p<0.001$) and task ($p=0.009$). SICI was smaller when the balance task was hard (28±3% inhibition) compared to easy (40±3%). Less SICI was also observed when the secondary task comprised of the motor (31±3% inhibition) compared to the cognitive task (38±3%).

CONCLUSION: The results of this study demonstrate that motor cortical control is affected by dual-tasking but that this effect depends on the type of the secondary task. Perhaps due to its higher dual-task cost, dual-tasking with a motor task resulted in an increase in CSE and decrease in SICI. Future work will examine whether dual-task training can further enhance this modulation.

OP-MH02 Health and Fitness: Ageing

LONGITUDINAL CHANGES IN LIFE-SPACE MOBILITY AND AUTONOMY IN PARTICIPATION OUTDOORS AMONG FINNISH COMMUNITY-DWELLING OLDER ADULTS FROM PRE-COVID-19 TO THROUGH THE PANDEMIC

LINDEMAN, K.1, KARAVIRTA, L.1, KOIVUNEN, K.1, KESKINEN, K.E.1, PORTEGIJS, E.2, RANTANEN, T.1

1 UNIVERSITY OF JYVÄSKYLÄ, 2 UNIVERSITY OF GRONINGEN

INTRODUCTION: We investigated changes in older adults' life-space mobility (LS) i.e. range and frequency of moving in a given period, and autonomy in participation outdoors (IPA) i.e. possibilities to go where one wants to from before the COVID-19 pandemic to through the pandemic. We studied whether pre-pandemic physical performance and driving status is associated with the prevalence and incidence of restricted LS (≤ 52.3 points), a threshold predicting an increased risk of activities of daily living (ADL) disability.

METHODS: Participants were community-dwelling people aged 75, 80, or 85 years at baseline in 2017-2018, of whom 657 took part in the survey during the COVID-19 Emergency Powers Act in 2020 and the second follow-up in 2021-2022. LS (range 0-120, higher score indicates higher mobility) and IPA (range 0-20, higher score indicates lower autonomy) were assessed by same validated questionnaires at each time point (1,2). Physical performance was assessed at baseline with the Short Physical Performance Battery (SPPB; impaired 0-9 p. vs. intact 10-12 p.) (3). Driving status (drivers vs. non-drivers) was self-reported. Changes in LS and IPA according to SPPB and driving status and their combinations were analyzed with generalized estimating equations (GEE). The prevalence and incidence of restricted LS were examined with GEE and binary logistic regression, respectively.

RESULTS: In 2020, LS and autonomy decreased (LS; M 74.2 SD 17.9 vs. M 63.5 SD 23.9, IPA; 4.9, 3.7 vs. 11.6, 5.1, p<.001). At baseline, driving and intact SPPB were associated with higher LS and better autonomy (p<.001). The decrease in LS was less steep among drivers with intact SPPB compared to three other groups (group*time interaction; p<.05 for all). From 2020 to 2021-2022, LS was restored to 66.6 (20.3) points, with a similar rate in four groups. Autonomy was restored to 6.7 (4.3) points, being more complete among drivers with intact SPPB than for drivers and non-drivers with impaired SPPB (group*time interaction; p<.05 for both). In 2021-2022, LS and autonomy were still lower than at baseline (p<.001 for all combinations). Compared to the baseline, the proportion of restricted LS increased to 36.8 % in 2020 and remained higher through the pandemic. Compared to the drivers with intact SPPB, all other groups had 3 to 4.5 times the odds of becoming restricted in LS during 2021-2022 (p<.05).

CONCLUSION: Among Finnish older adults, the COVID-19 pandemic accelerated the decline in LS and weakened IPA in 2020, and the losses were not fully reverted in 2021-2022. The decline of LS to below the threshold for increased ADL disability risk was observed to increase, which may translate to a higher proportion of ADL disability in the future. Drivers with intact physical performance were at lower risk for restricted LS than non-drivers or those with impaired physical performance.

LOW RELATIVE SIT-TO-STAND POWER IS ASSOCIATED WITH THE DEVELOPMENT OF FRAILTY, DISABILITY, AND COGNITIVE IMPAIRMENT IN OLDER PEOPLE: A 6-YEAR LONGITUDINAL STUDY

GARCIA-AGUIRRE, M.1,2, BALTASAR-FERNANDEZ, I.1,2,3, ALCAZAR, J.1,2, LOSA-REYNA, J.2,4, ALFARO-ACHA, A.2,5, ALEGRE, L.M.1,2, RODRIGUEZ-MAÑAS, L.2,6, ARA, I.1,2, GARCIA-GARCIA, F.J.2,5

INTRODUCTION: Relative sit-to-stand power (i.e., normalized to body mass) has been demonstrated to be an important predictor of frailty, limitations in activities of the daily living (ADL) and cognitive impairment in older adults (1-2). However, these associations have only been tested in cross-sectional studies, so no cause-effect relationship has been established yet. Thus, the aim of this study was to evaluate the relationship of low relative power with the development of frailty, disability in ADL, depression and cognitive impairment in older adults.

METHODS: A total of 895 older adults (Age range = 65 - 103 years; 46 % men) from the Toledo Study for Healthy Aging were included. Relative power was assessed through the 30-s sit-to-stand test and the Alcazars equation (1). Participants

were classified as having low relative power according to previously published cut-off points (<2.5 W·kg-1 in men and <1.9 W·kg-1 in women) (2), and moderate and high relative power based on the median value. Frailty was assessed according to the Fried's frailty phenotype (FP) (≥3) and frailty trait scale (FTS) (≥50), disability in basic ADL (Katz index <6), depression (geriatric depression scale (GDS) >4) and cognitive impairment (Mini-mental state examination (MMSE) <23), before and after 6 years of follow-up. Independent Student's t-test and logistic regression analyses adjusted for age, sex, education and comorbidities were used to analyze the data.

RESULTS: Relative power declined significantly in both men and women (-0.09 vs -0.07 W·kg-1 per year; −2.95 vs. −2.84% per year; respectively; p<0.05). In addition, low relative power at baseline in was significantly associated to the development of frailty FTS (OR [95%CI] = 2.69 [1.60 - 4.55]), frailty FP (OR [95%CI] = 2.81 [1.160 - 6.797]), cognitive impairment (OR 2.215 [95%CI] =2.215 [1.190 - 4.124]), and disability in basic ADL (OR 95%CI] = 1.850 [1.163 – 2.946]), but not depression (OR [95%CI] = 1.355 [0.848 – 2.165]), after the 6-year follow-up compared to the high relative power group, independently of sex, age, education and comorbidity.

CONCLUSION: Lower-limb muscle power declined at a rate of ~3% per year in both men and women. Importantly, low relative power at baseline was independently associated with the onset of frailty, cognitive impairment, and disability after 6 years of follow-up. Therefore, assessing relative power using the 30-s sit-to-stand muscle power test may help health professionals to prevent the development of future negative conditions at an early stage and improve the patient's prognosis.

A SINGLE BOUT OF BLOOD FLOW RESTRICTION TRAINING AND ACCENTUATED ECCENTRIC-ONLY TRAINING AFFECT DIFFERENT COGNITIVE FUNCTION SUBDOMAINS IN OLDER ADULTS: PRELIMINARY RESULTS FROM THE BRAIN-M TRIAL

VINTS, W.A.J., KIELE, D., KVEDARAS, M., ZIV, G., PÄÄSUKE, M., CESNAITIENE, V., LEVIN, O., MASIULIS, N.

LITHUANIAN SPORTS UNIVERSITY

INTRODUCTION: A single bout of exercise can transiently enhance cognitive performance in older adults. Exercise-induced increases in lactate (La) levels are suggested to play a role in the mechanism of this effect. Therefore, it has been proposed that high-intensity exercise may be the most optimal exercise protocol to enhance cognitive performance in older adults, yet mostly studied in aerobic exercise. We hypothesize that in resistance exercise not the relative intensity (i.e. % one-repetition maximum, %1RM), but rather the elevation of La would be associated with larger cognitive changes. Therefore, we aimed to compare the effects on cognitive function in older adults between two different resistance exercise interventions, with either a high metabolic (high La, low %1RM) or a high mechanic (low La, high %1RM) training stimulus.

METHODS: In this randomized controlled trial, 22 older adults (60-74y old) were allocated to a single bout of blood flow restriction training (BFRT, n = 10), accentuated eccentric-only resistance training (ECC, n = 6) or 45min seated rest (n = 6). Both exercise groups performed three lower body exercises at an equal relative volume % of 57.6% (number of exercises x sets x repetitions x %1RM). BFRT consisted of 4x12 repetitions at 40% 1RM and 50% lower limb occlusion pressure. ECC consisted of 4x4 repetitions at 120% 1RM. Two-way repeated measures ANOVA was used to assess pre-to-post 1min changes in La and pre-to-post 5min changes in cognitive function between the three groups. Cognitive tests included a 2-Choice Reaction Time test, Go/No-Go test, Memory Search test and Switching task. The main outcome measures were response time (RT, in ms) of the correct responses, and changes in performance index (PI; 100×[accuracy/response time of all responses]).

RESULTS: A significant interaction was found for La level changes ($p = 0.026$, partial $\eta^2 = 0.350$). BFRT (+3.55 ±2.67 mmol/L) significantly elevated La levels compared to the control group (+0.44 ±0.77 mmol/L), while La changes after ECC (+1.18 ±1.23 mmol/L) did not significantly differ from the other groups. A significant interaction was found for PI change on the Go/No-Go test ($p = 0.041$, partial $\eta^2 = 0.286$). Especially the BFRT group (+2.58 ±1.40), but also the ECC group (+1.90 ±2.41) improved their PI on the Go/No-Go test from pre to post compared to the control group (-0.20 ±2.30). ECC participants tended to improve more on the 2-Choice Reaction Time and Memory Search test, while BFRT participants tended to improve more on the Go/No-Go and Switching task (partial $\eta^2 > 0.06$, $p > 0.05$). After BFRT, higher La changes tended to correlate with Go/No-Go test PI and Switching task RT and PI changes ($R > 0.300$, $p > 0.05$).

CONCLUSION: A single bout of BFRT tended to improve performance on executive function tasks more than ECC, and this effect may be related to the larger increase in La induced by BFRT. Our results suggest that the role of La in enhancing cognitive performance may be specific to executive functions.

EFFECTS OF ONCE- VERSUS TWICE-WEEKLY MULTI-JOINT ECCENTRIC EXERCISE ON LOWER-LIMB MUSCLE FUNCTION AND STRUCTURE IN OLDER ADULTS

BAXTER, B.A., BAROSS, A.W., RYAN, D.J., TKADLEC, S., KAY, A.D.

UNIVERSITY OF NORTHAMPTON

INTRODUCTION: Resistance training combats sarcopenia in older adults by improving both muscular size and strength, although poor adherence rates to the twice-weekly guidelines can limit its effectiveness [1]. However, the high-force low-metabolic cost nature of eccentric resistance training has demonstrated greater adherence and functional adaptations

compared with traditional strength training, even by individuals with pre-existing health conditions [2]. Therefore, the present study examined the dose-response and temporal characteristics of eccentric resistance training by comparing the effects of once- and twice-weekly 12-week training on lower-limb muscle function and structure of older adults.

METHODS: Participants were randomly assigned to control (CON [n = 14]), once-weekly (G1X [n = 14]), or twice-weekly (G2X [n = 14]) experimental groups. Eccentric and isometric strength, rate of torque development (RTD), sit-to-stand (STS), vastus lateralis thickness, fascicle length and angle, and quadriceps femoris volume were measured at baseline (week 0), mid-training (week 7), and post-training (week 13). Training was performed unilaterally on an isokinetic stepper ergometer at 50% of maximal eccentric strength at 18 step/min for 7 and 9 min in weeks 1 and 2, respectively, then for 12 min at 24 step/min in weeks 3-12. Two-way mixed model ANOVAs were conducted to identify significant ($P < 0.05$) differences with effect sizes (ES) calculated to determine the magnitude of change.

RESULTS: Within G1X, one participant withdrew, whereas in G2X, two participants withdrew and one was not included in analyses due to low adherence (<80%). Compared to baseline, after six weeks of training significant increases in eccentric strength (294-338 N [ES = 1.01-1.76]) and muscle thickness (1.1-1.8 mm [0.78-1.35]) were detected in both training groups. Compared to baseline, after 12 weeks of training significant increases were observed in eccentric strength (415-498 N [1.38-1.88]), isometric strength (22-35 N·m [1.29-1.30]), RTD (69-95 N·m/s, [0.82-1.03]), STS performance (2.92-2.94 s [0.65-0.85]), muscle thickness (1.7-2.9 mm [1.05-1.56]), fascicle angle (1.5-2.0° [0.92-1.04]), and muscle volume (92-99 cm^3 [1.06-1.52]) in both groups. No significant change in fascicle length occurred in any group. No differences were revealed between G1X and G2X in any measure at any timepoint.

CONCLUSION: Once-weekly eccentric resistance training elicited similar improvements in neuromuscular function and structure compared to twice-weekly training in older adults. Given the difficulty older adults (and other exercise intolerant populations) have adhering to twice-weekly strength training programmes, these findings have important implications for clinical exercise prescription where substantial improvements in lower-limb muscle function and structure can be attained following once-weekly eccentric training.

A WEIGHT-BEARING STAIR-CLIMBING EXERCISE PROGRAM IS NOT INFERIOR TO MACHINE-BASED RESISTANCE TRAINING FOR IMPROVEMENTS IN MUSCLE POWER AND FUNCTIONAL CAPACITY AMONG OLDER ADULTS

VAN ROIE, E., DELECLUSE, C.

KU LEUVEN

INTRODUCTION: Improvement in maximal lower-limb muscle power (Pmax) is a crucial target for resistance training (RT) in older adults. Machine-based RT can induce large gains in Pmax. However, many older adults are reluctant to initiate a training program in a traditional fitness center, stressing the importance of weight-bearing alternatives. Therefore, this study compared the effects of a machine-based RT and a stair-climbing exercise program (STAIR) on Pmax, force-velocity (F-V) profile and functional capacity in older adults.

METHODS: Older adults (♂30 ♀16; 70.9 ± 4.3 years) were randomly assigned to RT (n=23) and STAIR (n=23). RT used a leg press (Leg Press CC, HUR, Kokkola, Finland) and STAIR a step with adjustable height and a flight of stairs (2 x 6 steps) as training tool. Training sessions were performed in the lab, twice weekly for 12 weeks, and supervised by experts. In the first 4 weeks, exercises were performed at controlled speed (hypertrophy-oriented; 4 x 12-15 repetitions; 60% of one-repetition maximum (1-RM) in RT; step-up exercise with height of 30-40 cm in STAIR), in the following 8 weeks as fast as possible (power-oriented, 4 x 12 repetitions; 40% of 1-RM for RT and 4 x 2 flights of 6 steps for STAIR). Pre and post intervention, the following outcomes were measured: leg-extensor F-V profile (Pmax, maximal force (F0), maximal velocity (V0), the slope divided by F0 (SFV/F0)) and functional capacity.

RESULTS: Two participants dropped out in RT, none in STAIR. The results revealed an increase over time for Pmax, F0, V0 and SFV/F0 (all $P < 0.01$), but no interaction effects (all $P > 0.10$, $\eta 2$ 0.02-0.05). A greater increase in 6-step stair ascent power was found in STAIR (+13.3 ± 13.5%) compared to RT (+4.9 ± 13.9%, Ptime = 0.002, Pint = 0.04, $\eta 2 = 0.10$). Similar improvements were found in STAIR and RT on 5-repetition sit-to-stand power (Ptime = 0.002, Pint = 0.17, $\eta 2 = 0.05$) and 10m fast walk (Ptime < 0.001, Pint = 0.29, $\eta 2 = 0.03$). No time ($P = 0.44$) nor interaction effect ($P = 0.15$, $\eta 2 = 0.05$) was found for countermovement jump height.

CONCLUSION: It appears that a weight-bearing stair-climbing exercise program is not inferior to machine-based RT for improvements in Pmax and its F-V components. Both programs resulted in an improved force production, in particular at high velocities (as evidenced by a significant change in the slope of the F-V relationship), and simultaneous improvements were found on functional capacity tests. The stair-climbing exercise program was beneficial over machine-based RT for gains in stair-climbing performance, which is in line with the principle of training specificity. Future research should investigate whether similar effects are found when the stair-climbing exercise program is implemented in a home-based setting with limited expert oversight.

OP-MH07 Cardiovascular disease/Stroke (incl. ESSA-ECSS Exchange)

ESSA-ECSS EXCHANGE: FEASIBILITY AND SAFETY OF EARLY-INITIATED CARDIAC REHABILITATION IN STROKE SURVIVORS TO IMPROVE SURVIVORSHIP (CRISSIS)

MACHADO, N., OLVER, J., WILLIAMS, G., JOHNSON, L.

EPWORTH HEALTHCARE, UNIVERSITY OF MELBOURNE, MONASH UNIVERSITY, AUSTRALIAN CATHOLIC UNIVERSITY

INTRODUCTION: Multiple National Clinical Guidelines for Stroke Management recommend the early commencement of cardiorespiratory fitness (CRF) training after stroke. But it is unclear if it is safe and feasible to do so. The aim of this study is to investigate the safety and feasibility of early-initiated CRF testing and training within a program of stroke-adapted cardiac rehabilitation.

METHODS: People with ischaemic stroke admitted to Epworth Rehabilitation were screened for eligibility and invited to participate in a stroke-adapted cardiac rehabilitation program, consisting of CRF training 3-days per week during inpatient rehabilitation, and 2-days per week CRF training + health education for 6-weeks during outpatient rehabilitation. A submaximal CRF test, measures of physiological function, fatigue, mood, and quality of life were taken pre- and post-intervention, and at 3-month follow-up.

RESULTS: Between April 2018 and December 2019, 164 people with stroke were screened, 117 (71.3%) were eligible, with 62 (53%) consenting to participate. 10 participants ceased the study due to: lack of time (n=1), transferred to acute hospitals (n=3) or declined further participation (n=6). Five unrelated adverse events were reported. Following consent, 41 (66%) participants were able to complete the fitness test early post stroke and 49 (79%) completed CRF training during inpatient rehabilitation. Participants attended 94% of scheduled sessions. The minimum recommended CRF training intensity (40% heart rate reserve) and duration (20 minutes), as per the exercise guidelines for people with stroke, was achieved by 57% and 55% of participants, respectively during inpatient rehabilitation.

CONCLUSION: Preliminary data suggests early initiated stroke-adapted cardiac rehabilitation is: 1) safe, and 2) feasible for some people with stroke. High attendance and retention rates were observed, but not all people with stroke could achieve the recommended minimum intensity and duration of CRF training early post stroke.

STROKE-HEART SYNDROME: SEX-SPECIFIC INCIDENCE AND RISK FACTORS FOR MAJOR ADVERSE CARDIOVASCULAR EVENTS IN 682,203 PATIENTS WITH ISCHAEMIC STROKE

BUCKLEY, B.J.R., HARRISON, S.L., LANE, D.A., HILL, A., LIP, G.Y.H.

LIVERPOOL JOHN MOORES UNIVERSITY

INTRODUCTION: Newly diagnosed cardiovascular complications post-stroke, termed stroke-heart syndrome, are common and associate with worsened prognosis. We therefore investigated the sex-specific incidence and 5-year major adverse cardiovascular events following stroke-heart syndrome, by pre-existing risk factors (age, obesity, hypertension, type 2 diabetes mellitus (T2DM), and high LDL cholesterol).

METHODS: A multi-centre cohort study was conducted using anonymised electronic medical records from 56 participating healthcare organizations. Patients with incident ischaemic stroke aged ≥18 years with 5-years of follow-up were included. Patients diagnosed with new-onset cardiovascular complications (heart failure, severe ventricular arrhythmia, atrial fibrillation (AF), ischaemic heart disease, Takotsubo syndrome) within 4-weeks of incident ischaemic stroke (exposure) were 1:1 propensity score-matched (age, sex, ethnicity, comorbidities, cardiovascular care) with ischaemic stroke patients without newly diagnosed cardiovascular complications (control).

Cox proportional hazards regression models reported hazard ratios (HR) with 95% confidence intervals (CIs) and Kaplan-Meier curves for 5-year risk of all-cause mortality, recurrent stroke, and acute myocardial infarction (AMI).

RESULTS: Of 682,203 patients with ischaemic stroke, 20% (n=135,834) presented with stroke-heart syndrome (49% (n=67,008) female and 50% (n=67,683) male). Following propensity score matching, composite stroke-heart syndrome associated with significantly higher risk of 5-year mortality (HR 1.47 (95%CI 1.44, 1.49) P<0.01), recurrent stroke (1.12 (1.11, 1.13) P<0.01), and AMI (2.50 (2.43, 2.58), P<0.01). These outcomes were similar for males and females and all investigated risk factors associated with worsened prognosis compared to matched controls. Of the modifiable risk factors, T2DM associated with the highest risk of mortality and AMI. Hypertension, T2DM, and high LDL associated with the highest risks of recurrent stroke.

CONCLUSION: Incidence and 5-year major adverse cardiovascular events following stroke-heart syndrome were similar for females and males. All investigated risk factors associated with worsened prognosis. Type 2 diabetes mellitus seemed particularly important for mortality and AMI, and hypertension, type 2 diabetes mellitus and high LDL cholesterol seemed particularly important for recurrent stroke.

INVESTIGATING THE DOSE RESPONSE RELATIONSHIP BETWEEN PHYSICAL ACTIVITY AND STROKE BETWEEN NORM- AND HYPERTENSIVE (MEDICATED AND NON-MEDICATED) SUBJECTS: A COHORT STUDY AMONG 140,000 ADULTS.

MCLELLAN, H., DAWSON, E.A., THIJSSEN, D.H.J., BAKKER, E.A.

LIVERPOOL JOHN MOORES UNIVERSITY

INTRODUCTION: Regular physical activity (PA) demonstrates a strong dose-dependent relationship with the risk of stroke. Interestingly, recent studies suggest that the dose-dependent protection of regular PA is attenuated in the presence of cardiovascular risk and/or disease. Hypertension is the most important risk factor for stroke. However, no previous study explored whether hypertension (and associated medication) interacts with the benefits of regular PA. Therefore, the aim of this study was to compare the dose-response relationship between PA and stroke between normo- and hypertensive subjects.

METHODS: A cohort study was performed in the Netherlands (data from 2006-2018, median follow up of 6.75 years. A total of 140,000 participants (44±13 years, 41% male) were stratified at baseline as hypertensive (i.e. systolic >130 and/or diastolic >80 mmHg, or self-reported physician diagnosed hypertension with the use of blood pressure lowering medication: 61,638) or normotensive (n= 78,311). Individuals were categorised into quartiles of lowest (Q1) to highest (Q4) PA based on self-reported moderate to vigorous PA (MVPA) volumes. Primary outcome was stroke. Cox regression was used to estimate hazard ratios (HRs), 95% confidence intervals (Cis) and P values. The main analyses were stratified on baseline blood pressure (hypertension versus normotension) and adjusted for age, sex, income, education level, alcohol consumption, kidney function, BMI, glucose, SBP, DBP, low density lipoprotein, use of acetylsalicylic acid, anti-platelets and antihypertensive medication.

RESULTS: Compared to the lowest PA quartile (Q1), adjusted HRs for individuals with normotension were 0.79 (95% CI 0.50 to 1.25, P=0.32), 0.75 (95% CI 0.48 to 1.18, P=0.22), 0.97 (95% CI 0.62 to 1.51, P=0.90) for PA Q2 to Q4, respectively. In hypertensive subjects, HRs for the risk of stroke in Q2 to Q4 compared to physically inactive individuals (I.e., Q1) were 0.89 (95% CI 0.68 to 1.17, P=0.41), 0.74 (95% CI 0.56 to 0.98, P=0.03), 0.92 (95% CI 0.69 to 1.23, P=0.56). There was no significant difference in risk reduction between normo- and hypertensive subjects for Q2, Q3 and Q4 (P=0.63, 0.93,0.71 respectively). Comparing medicated (n=13,178) versus non-medicated hypertensive individuals (n=48,460), a trend was observed for a smaller benefit of PA in medicated hypertensives for all MVPA volumes. Adjusted HRs for Q2 were 0.85 (95% CI 0.61-1.18, P=0.32) and 0.96 (95% CI 0.61-1.52, P= 0.89), for Q3 were 0.67 (95% CI 0.47-0.94, P=0.02) and 0.88 (95% CI 0.56-1.39, P=0.58) and for Q4 were 0.81 (95% CI 0.57-1.16, P=0.26), 1.15 (95% CI 0.70-1.89, P=0.59) for medicated and non-medicated hypertensives, respectively.

CONCLUSION: Our analysis reinforces the benefits and dose-dependent protective effect of PA on the reduction in stroke risk, which is not affected by the presence of hypertension. Use of anti-hypertensive medication, however, may interfere with the protective impact of PA on stroke risk.

CARDIOPROTECTIVE EFFECT OF INTRADIALYTIC EXERCISE ON LEFT ATRIAL MECHANICS.

MAUFRAIS, C.1, JOSSE, M.1, PATRIER, L.2,3, ISNARD, M.4, TURC-BARON, C.2,5, GRANDPERRIN, A.1, NOTTIN, S.1, MANDIGOUT, S.6, CRISTOL, J.P.2,5,7, OBERT, P.1

1.LAPEC - AVIGNON UNIVERSITY, 2. AIDER SANTÉ, 3. CHU NÎMES, 4. ATIR AVIGNON, 5. CHRU, MONTPELLIER, 6. LABORATORY HAVAE EA-6310, UNIVERSITY OF LIMOGES, 7. PHYMEDEXP, UNIVERSITY OF MONTPELLIER

INTRODUCTION: The left atrial (LA) function plays an important role in cardiac performance by modulating left ventricular (LV) function. Alterations in LV function are commonly reported during hemodialysis, but available data describing changes in LA function are limited. There is growing evidence of the cardioprotective effect of intradialytic exercise (IDE) on the LV function but studies analyzing its effect on LA myocardial function are scarce.

METHODS: This prospective, open-label, two-center randomized crossover trial aimed to evaluate the effect of IDE on LA strains using speckle-tracking echocardiography. Fifty-six stable individuals receiving hemodialysis for more than 3 months participated in a random order in 2 hemodialysis sessions: standard hemodialysis (HD) and a session incorporating 30 min of aerobic exercise (HDEX). LA and LV global longitudinal (GLS) strains were obtained at before (T0) and at peak stress (i.e. 30 min before hemodialysis-ending).

RESULTS: IDE totally abolished the decline in LA reservoir strain observed during HD (HD: -4.7±7.5% vs HDEX: -1.6±6.9%; 3.1%, 95%CI: 0.3/5.9, p=0.03) whereas it did not affect the other components of LA mechanics. A similar result favoring IDE intervention was also demonstrated on GLS changes from T0 to Tpeak (p<0.001). Between-session differences of changes in GLS and LA reservoir strain were correlated (r=-0.32, p=0.03). The cardioprotective effect of IDE disappeared in patients with LA enlargement (i.e.>34 mL/m²).

CONCLUSION: A single bout of 30 minutes of intradialytic cycling was sufficient to limit the hemodialysis-related reduction in LA reservoir function. Loading conditions and ultrafiltration volumes were similar between HD and HDEX, suggesting that the benefits of IDE on LA reservoir function were not related to hemodynamic factors. Furthermore, between-session differences of changes in GLS and LA reservoir strain were correlated, indicating that the relative preservation of LV systolic function by IDE partially explains that of LA reservoir function. Other mechanisms must be advanced. The cardioprotection conferred by IDE on LV systolic function has already been explained via a reduction of hemodialysis-induced perfusion abnormalities. Since ischemia also impairs LA relaxation and compliance, we can reasonably speculate that IDE might have also preserved LA myocardial perfusion (and thus its relaxation properties and compliance), thereby limiting the impairment in LA reservoir function.

Interestingly, the cardioprotective effect of IDE was however lost in patients with pathological LA remodeling. The higher degree of interstitial fibrosis associated with LA enlargement may have weakened the cardioprotective effects of exercise preconditioning.

Conclusion. IDE represents an interesting non-pharmaceutical therapeutic strategy to attenuate acute hemodialysis-related cardiac complications. Further studies are needed to evaluate the clinical impact of the repetitive cardioprotective effects of IDE on LA function

THE ASSOCIATIONS BETWEEN THE UNHEALTHY BODY WEIGHT AND PHYSICAL FITNESS OF THE ELDERLY IN CHINA: A CROSS-SECTIONAL STUDY

CHAOQUN, F.

CHINA INSTITUTE OF SPORT SCIENCE, BEIJING, CHINA

INTRODUCTION: Too high and too low body weight are unhealthy manifestations, prone to a variety of diseases, affecting the quality of life of the elderly. The paper aimed to to analyze the proportion of unhealthy body weight of the elderly in China through national data and investigate the association between different levels of health-related physical fitness measurements and BMI status in Chinese elderly through national data.

METHODS: A cross-sectional study was conducted in 39973 elderly people (49.5% males) aged 60-79 years in 31 provinces of Chinese Mainland. And the data is from the 5th National Physical Fitness Surveillance data in China, and the collection period is from August to November 2020. The demographic information of the subjects was obtained through the questionnaire, including age, gender, the home, education level, pre-retirement occupation, marriage, exercise, sleep, smoking and physical self-evaluation. Body weight status was divided into four groups by BMI: low body weight, normal body weight, overweight and obesity. Physical fitness indicators including height, weight, Waist and hip circumference, body fat percentage, 2 minutes step test, sit and reach test, 30 seconds sit-up test, standing with eyes closed and one foot, reaction time was measured. The quartiles of each physical fitness measurement were used for unconditional logistic regression analyses.

RESULTS: (1) The total rates of low body weight, overweight and obesity among the elderly in China were 2.4%, 41.7% and 16.7% respectively（$P<0.001$）, and the detection rate of low body weight increased with the increase of age（$P<0.001$）. (2) In general, the physical performance of elderly men and women in the normal weight group were better than those in the overweight, obese and lean groups respectively; (3) There is a clear negative correlation between cardiopulmonary endurance and unhealthy body weight. Low level of cardiopulmonary endurance can increase the risk of low body weight by 51% - 68% and 31% - 40% respectively for elderly men and women, and increase the risk of overweight and obesity by 4% - 57% for elderly men and 5% - 66% for elderly women. Poor limb muscle strength performance will increase the risk of overweight and obesity by 10% to 61% in older women, respectively, but there is no clear relationship in older men. At the same time, the relationship between low-level flexibility, balance and reaction ability and overweight and obesity is not clearly reflected.

CONCLUSION: According to the results, two physical fitness measurements clearly

predicted the risk of overweightness and obesity. Specifically, maintaining good cardiopulmonary endurance and muscle strength level may effectively promote the improvement of the poor weight status of the elderly, so as to obtain more health benefits. However, further research on the association between flexibility and obesity status is still needed.

OP-AP11 Statistics: Challenges and Applications

ATTITUDES TOWARDS AND PERCEPTION OF REPRODUCIBILITY AND REPLICABILITY IN SPORTS AND EXERCISE SCIENCE

MURPHY, J., WARNE, J.

TECHNOLOGICAL UNIVERSITY DUBLIN

INTRODUCTION: There are formal calls for increased reproducibility and replicability in sports and exercise science, yet, there is minimal information on the overall knowledge of these concepts at a field-wide level. A survey was conducted to explore the attitudes and perceptions of active researchers towards reproducibility and replicability in sports and exercise science.

METHODS: Sports and exercise science researchers was recruited via the Web of Science mailing list of published authors to complete the survey, which was adapted from a Nature survey (Baker & Penny, 2016, Nature, 533 (7604), 452–454). Responses were analysed using descriptive statistics (for multiple choice responses) in R statistical software and thematic analysis (for open text box responses).

RESULTS: Of the 511 respondents, 42% (n = 217) believe there is a significant crisis of reproducibility or replicability in the field of sports and exercise science while 36% (n = 182) believe there is a slight crisis. 3% (n = 15) of respondents believe there is no crisis while 19% (n = 95) did not know. Insufficient mentoring, low statistical power, selective reporting of results, and pressure to publish were identified as the highest contributing factors to poor reproducibility and replicability. Four

themes were generated in the thematic analysis: the research and publishing culture, educational barriers to research integrity, research responsibility to ensure reproducibility and replicability, and current practices facilitating reproducibility and replicability. Researchers believe that engaging in open science can be detrimental to career opportunities due to lack of incentives. They also feel journals are a barrier to reproducible research due to high publication charges and a focus on novel research. Journals appear to act as gatekeepers in science and have too much research responsibility. Statistical expertise was identified as a key factor for improving reproducibility and replicability in the future, particularly, a better understanding of study design and different statistical techniques.

CONCLUSION: Statistical education should be prioritised for early career researchers which could also positively affect peer review. Researchers must accept responsibility for reproducibility and replicability through thorough project design, appropriate planning of analyses and transparent reporting practices.

DE NOVO ANALYTICAL FRAMEWORK ON COMPUTATIONAL EXERCISE PHYSIOLOGY VIA DYNAMICAL MODELING AND AI ALGORITHMS

TAO, K., HUANG, Y.

BEIJING SPORT UNIVERSITY

INTRODUCTION: In the area of computational sports medicine, clinical and experimental data have been explosively increased due to the development of medical facilities. Under this circumstance, de novo techniques to analyze data emerge. Our work rigorously presents two modeling frameworks, dynamic models and artificial intelligent algorithms in the background of investigating sarcopenia mechanism and the maximal heart rate estimation, respectively.

METHODS: Here, we proposed a minimal regulatory network and developed a dynamic model to rigorously investigate the mechanism of sarcopenia. Our model was consisted of eight ordinary differential equations and incorporated linear and Hill-function terms to describe positive and negative feedbacks between protein species, respectively. All recruited subjects visited the laboratory for screening and signed an informed consent form one week prior to the beginning of the study. Alcoholic drinks were prohibited on the day of the test, and coffee and tea consumption was ceased at least 1 h before the test. All participants have provided informed consent at the time of enrollment. Additionally, an artificial neural network (ANN) was applied to accurately evaluate the maximal heart rate based on experimental data from 121 middle-aged adults at an average age of 57.2 years with an average body mass index (BMI) of 25.9, after performing on a power bike with a starting wattage of 0 W that was increased by 25 W every three min until the experiment terminated. The data were randomly divided into two subsets.

RESULTS: With the technique of dynamical modeling, A total of 720 samples with 10 scaled intensities were included in simulations, which revealed the expression level of AKT (maximum around 3.9-fold) and mTOR (maximum around 5.5-fold) at 3, 6, and 24 h at high intensity, and non-monotonic relation (ranging from 1.2-fold to 1.7-fold) between the graded intensities and skeletal muscle mass. Furthermore, continuous dynamics (within 24 h) of AKT, mTOR, and other proteins were obtained accordingly. Meanwhile, for the new technique to process data, the input variables for ANN were selected by correlation for the reduction of dimension. The accuracy of estimation by multivariate regression model and ANN were 9.74% and 9.42%, respectively, which outperformed the traditional age-based model (with an accuracy of 10.31%).

CONCLUSION: The de novo modeling framework sheds light on the interdisciplinary methodology integrating computational approaches with experimental results, which facilitates the deeper understandings of exercise training and sarcopenia. At the meantime, artificial intelligent algorithms provide comprehensive approaches to estimate the maximal heart rate using multiple indicators, revealing that ANN incorporated with age, resting heart rate, and second-order heart rate are more accurate than univariate models.

ESTIMATING THE INTENSITY WORKOUT USING AN HIDDEN MARKOV MODEL AND THE IMPACT OF MENSTRUAL CYCLES

STORME, F., CHASSARD, T., CARLIN, H., DURMION, G., TOUSSAINT, J.F., ANTERO, J.

INSTITUT NATIONAL DU SPORT, DE LEXPERTISE ET DE LA PERFORMANCE

INTRODUCTION: The impact of womens hormonal cycles of training and performance is central to the customization of training programs. Several studies have shown potential changes in the stages of menstrual cycles in efforts. In this study, we focus on high intensity training and its links with time factor and especially menstrual cycles for cyclists.

METHODS: We used as a Hidden Markov Model trained on the heart rate and powermeter captors streaming data to identify different training regimes. The dataset is collected from 16 elite (international level) and semi-elite women cyclists, sessions without missing values from the streams are kept (N=6303 sessions) and span from June 2017 and November 2022. The time spent in each state is then aggregated and used for time-dependent analysis of the different sessions regarding the reported data of the menstrual cycle. We collected menstrual data for 14 of the athletes included in the sessions dataset over several months (median follow-up time: 178 days) overlapping the session collection time. This collection is based on declarative data from the athletes (beginning and end of menstruations). The other phases of natural cycles are inferred using the method developped in [1]. In order to assess the influence of menstrual cycles, we focus on regular cycles of nature (not using contraceptive pills) athletes (N=9 athletes). Note that we used as a stringent criterion for regular cycles: a cycle length between 22 and 35 days and a variation over the last three cycles less than 7 days.

RESULTS: We found an important connection between high intensity sessions (Kruskal Wallis test: p-value=0.009), the time spent in the high intensity state and the menstrual phase for the regular cycles of female athletes (40 selected trainings for

3 athletes resulting of a sample of 17 cycles) . The time spent in the high intensity state is also closely related to the self-assessed training intensity of the athletes (session RPE) (pearson correlation = 0.4).

CONCLUSION: As with other studies focusing on elite female athletes, the number of participants limits some of our findings regarding statistical significance. However, our results are aligned with other studies [2] and show an influence of hormone cycles on the performance of elite female athletes.In addition, the Hidden Markov Model approach can be used to give coaches insights to assess compliance with training instructions as well as fitness and fatigue in multi-day competitions.

DETERMINANTS OF PERFORMANCE IN ELITE FENCING: A DELPHI STUDY OF FOIL, EPEE, AND SABER INTERNATIONAL LEVEL COACHES.

VARESCO, G.1, HAGER, R.2, DORON, J.1, JUBEAU, M.1

NANTES UNIVERSITÉ

INTRODUCTION: Fencing is an open-skilled combat sport present in the Olympics since 1896. Performance in fencing has been studied mostly from a physiological and technical perspective, but it also depends on tactical, psychological, and social factors. Thus, it is challenging to objectively investigate the main determinants of fencing performance at elite level. Qualitative research involving high-level fencing coaches could help to identify the key factors to perform at elite level. The aim of this study was to (1) understand the determinants of performance in fencing across the different weapons (foil, épée and saber) and (2) rank the extracted determinants from the most important to the less important.

METHODS: Thirty-one experts who coached foil (n = 8), epee (n = 8), or saber (n= 16) at international level participated in a three-round online Delphi survey. Round 1 asked coaches to identify the determinants of performance in their respective weapon. Common or similar determinants were combined. Round 2 asked coaches to rate the importance of each determinant using a Likert scale (range: 0 = not important to 9= extremely important). Determinants reached a consensus if the score had an interquartile range ≤1. Round 3 was similar to Round 2, but presented solely the determinants that did not reach an agreement, plus an anchor for each determinant, that consisted of the mean value obtained in Round 2.

RESULTS: A total of 25 determinants of fencing performance for the foil, 24 for the epee, and 42 for the saber were reported in Round 1, of which 17, 11 and 39 reached consensus after Round 3 for the foil, epee and saber, respectively. Common determinants across the three disciplines were information scanning and processing, coordination capacity, the ability to repeat efforts at high intensity, good tactic and technique, the ability to surpass yourself, determination, motivation, the attraction for challenges, prophylaxis, injury prevention, and the quality of the entourage (e.g. family, friends). Specific to the disciplines, most of the coaches for the epee agreed mostly on physiological, technical and strategical qualities being determinants for performing well at elite level, while in foil and saber emotion regulation was also considered important.

CONCLUSION: These findings, despite being based on the coaches opinion, offer a base for future studies planning interventions to improve performance in fencing. Some applications can be talent identification and optimization of training practices. Moreover, these results might be useful the development of discipline-specific tests to monitor training in fencers.

ADVANCED MODELING IN SPORTS SCIENCES: THE STUDY CASE OF EXERCISE-INDUCED HYPOXEMIA

BOUDRY, F., MERIC, H., DURAND, F.

UNIVERSITÉ DE PERPIGNAN VIA DOMITIA

INTRODUCTION: Exercise-Induced Hypoxaemia (EIH) phenomenon is present in some endurance-trained athletes. Its consequences on adaptations to exercise during acute and chronic exposure to altitude have been recently published [1], suggesting that responses to altitude training could be linked to it. Determined at sea level, considering the drop of oxygen saturation during a maximal exercise ([2 - 4]), EIH is not always detected in athletes before altitude training. Thus, the aim of this study is to determine EIH without a direct indicator of the phenomenon. As Artificial Intelligence (AI) and computational approaches are powerful and seems promising for sport sciences development [5] we used those approaches in this work.

METHODS: To investigate this phenomenon, we used 127 endurance trained athletes data measured during previous stress test including anthropological variables (age, height, weight and sex), physiological variables (heart rate, gas exchanges, start and end saturation) and training information (years of training, training volume and sport). Three data sets were created using those data: the first with raw (measured) values, the second using relatives (to the maximal measured) values and the last one using data resulting from a principal component analysis. Those data were then analyzed using a newest version of the Gradient Boosted Machine (GBM): Light Gradient Boosted Machine (LGBM), whose parameters were tuned using the optuna framework.

RESULTS: Our approach that aimed to classify EIH or non-EIH athletes had a correct prediction in about 79% of the time (35 out of 44 in the test data set, with Kappa = 0.59). Furthermore, we were able to determine the most important factors used

to discriminate EIH athletes: training years, maximal and minimal ventilation, minimal heart rate and maximal oxygen consumption .Those results show that Machine Learning (ML) method can be more powerful and allow new approaches.

CONCLUSION: Our study demonstrates that AI and especially ML could be applied to detect EIH afterwards. This possibility could be a supplemental tool for coaches and scientists and could allow to re-investigate data about altitude training in order to better understand the inter-individual responses and individualize the monitoring.

(2) Normandie Université Caen (France), CerreV

(3) Normandie Université Caen (France), UFR STAPS

Abstract

As shown by a recent meta-analysis (Laborde, Zammit et al., 2022), breathing techniques are used by athletes to enhance performance. Among them, slow-paced breathing (SPB), the voluntary slowing down of breathing frequency, was found to increase cardiac vagal activity (CVA; Laborde, Allen, et al., 2022), which is associated to enhanced stress management and emotion regulation. Most of the times, SPB is performed at the standard frequency of 6 cycles (inhalation/exhalation) per minute (cpm). However, whether the effects of SPB on psychophysiological outcomes change according to the respiratory frequency used is still unknown. The aim of this study was to investigate the effects of a brief SPB intervention (i.e., 5min) on CVA, as indexed non-invasively via heart rate variability (HRV) measurement. A total of 75 athletes (22 female; Mage =22.32; age range = 19-31) took part in the study. They had to come once to the lab, and performed 6 breathing conditions: at 5cpm, 5.5cpm, 6cpm, 6.5cpm, 7cpm; as well as a control condition with spontaneous breathing. HRV was measured, and CVA was indexed via the root mean square of the successive differences (RMSSD). Results showed that the control condition differed from all other SPB conditions ($F(2.404, 177.873) = 60.295$, $p < .001$, partial $\eta 2 = .45$; post-hoc tests with 5cpm (Cohen's d = 1.13), 5.5cpm (Cohen's d = 1.118), 6cpm (Cohen's d = 1.125), 6.5cpm (Cohen's d = 1.073) = 1.073, 7cpm (Cohen's d = 0.988)), however the different frequencies did not differ between themselves. To conclude, we can say that slowing breathing frequency to a range from 5cpm to 7cpm represent an effective method to increase CVA, which in turn is suggested to lead to improvements in stress management and emotion regulation. A short SPB exercise may therefore be seen as effective for athletes as a pre-performance routine, as well as during short breaks during the competition.

NONVERBAL BEHAVIOR AND EMOTIONS IN THE CONTEXT OF SPORTS

FURLEY, P.

GERMAN SPORT UNIVERSITY COLOGNE

According to evolutionary accounts of nonverbal expressions, humans have evolved to be well-equipped for communicating important internal states like emotions or social intentions nonverbally. Somewhat surprisingly, research on body

language (nonverbal behavior) in sport is only slowly emerging, although it is considered important and has been frequently studied in other disciplines. In this presentation, I attempt to introduce a bio-cultural framework and methodological guidelines for studying nonverbal behavior and, in particular, emotion expressions in sports. I argue that the ubiquity of (intense) emotional expressions and the wide-ranging documentation and coverage of sports events provides an ideal context for studying naturally occurring emotional expressions and their influence on interpersonal outcomes. I will outline the latest empirical research from our group showing that athletes, coaches, and referees' display certain nonverbal behaviors that are correlated with various internal (e.g., emotions) or contextual (e.g., success, playing location) variables and that observers can decode these nonverbal behaviors. In addition, I will discuss recent studies that show that these (emotional) nonverbal expressions by athletes and officials have the potential to influence other people and thereby influence various relevant outcomes in sports. Recommendations for future research will be made on how researchers can exploit the fact that nonverbal behavior often informs observers about what is going on inside a person and thereby gain insights on the reciprocal relationships between contextual factors, the athlete, and performance in sports.

EFFECTS OF A PHYSICALLY CHALLENGING ADVENTURE PROGRAMME ON GENERAL SELF-EFFICACY AND RESILIENCE: RANDOMISED CONTROLLED TRIAL

TYNE, W., FLETCHER, D., PAINE, J.N., STEVINSON, C.

LOUGHBOROUGH UNIVERSITY

Effects of a Physically Challenging Adventure Programme on General Self-efficacy and Resilience: Randomised Controlled Trial

Tyne, W.P., Fletcher, D., Paine N.J., Stevinson, C.

School of Sport, Exercise and Health Sciences, Loughborough University, UK

Introduction

Adventure programmes involving recreational physical challenges (e.g. high ropes courses and rock climbing) are popular with employers and educators to develop valuable psychosocial skills among their staff and students. These programmes are designed to take participants outside of their everyday comfort zone through exposure to physically and psychologically challenging activities in novel environments. Growing evidence supports their value in improving an array of interpersonal and intrapersonal skills, however, the quality of evidence has been critiqued and few rigorous controlled investigations exist. The present research examined the impact of an adventure-based intervention through a randomised controlled trial.

Methods

A total of 107 adults (52% male; mean age 25 years) were randomly allocated to an intervention group, which involved a half-day high ropes challenge course, or a waitlist control group. Self-report measures of general self-efficacy, resilience, risk-taking propensity and perceived stress were administered four weeks before and four days after the intervention. Assessments of participants' affective valence and perceptions of the intervention were also taken immediately after participation. Data were analysed through multivariate analysis of variance (MANOVA).

Results

MANOVA results showed an overall medium, statistically significant (Wilks' Lambda(4, 92)=5.263, p=.001, np2=.186) time * group effect. Further examination of univariate effects for dependent variables revealed a medium (np2=.152) time * group effect for changes in self-efficacy and a small effect (np2=.040) for risk-taking propensity and no significant differences for perceived stress (np2=.001) and resilience (np2=.010). Bivariate correlation analyses indicated that baseline self-efficacy scores negatively correlated with post-intervention self-efficacy change (r=-.556, p<.000), indicating that those with initially low levels of self-efficacy showed the greatest change. Correlation analyses also revealed that participants who felt a greater sense of challenge, engagement and affective valence after participation reported larger positive changes in study outcomes.

Discussion

These findings provide support for the effectiveness of adventure programmes using recreational physical challenges for increasing general self-efficacy among adult participants. The inclusion of such interventions within workplace and educational training programmes may enhance positive psychological development. Further research should explore if changes in intrapersonal outcomes translate into desirable workplace and educational outcomes, such as employee productivity and academic performance.

SYSTEMATIC REVIEW OF CHOKING UNDER PRESSURE IN MOTOR PERFORMANCE

CHAREYRE, L., CHALABAEV, A., ISOARD-GAUTHEUR, I.

UNIVERSITY OF GRENOBLE ALPES

Introduction: Anyone can experience choking under pressure and it is especially common in sports where performance is the focus. The present literature review focuses on "choking under pressure", which refers to a sub-optimal sporting performance that occurs under stressful conditions. This systematic review aims at examining the conditions (i.e., the moderators like as example the types of pressure) in which choking under pressure influences motor performance and the mechanisms that may explain it (i.e., mediators as for example the arousal).

Method: This systematic review was conducted following PRISMA Guidelines. We systematically searched relevant articles in PubMed, PsycINFO, PsycArticles, SPORTdiscus, Psychology and Behavioral Sciences Collection, Web of Science and Eric from inception to February 2023. We only included studies focusing on motor tasks (i.e., body movements assessed on coordination, or conditioning, or both).

Results: 642 articles were identified from the databases. Out of 368 articles (without duplicates) that were screened, 94 studies met the inclusion criteria for the first and 69 studies for the second screening review. Among the studies who examined the effect of choking under pressure on motor performance, most of them examined at least one moderators/mediators. Specifically, regarding moderators, studies mainly focused on the types of pressure (e.g., financial incentive or video recordings), on task characteristics (e.g., well-learned task or complex/simple task) and on others (e.g., emotional regulation or personality). Regarding mediators, studies mainly focused on distraction-related mechanisms (attention shifts from task-relevant to irrelevant cues), on arousal (e.g., heart rate or self-reports of arousal), on anxiety, on self-focus (e.g., self-awareness or self-consciousness).

Conclusion: Overall, our findings identified several conditions under which choking under pressure occurs, and showed that several mechanisms are involved in choking under pressure effects on motor performance.

OP-AP06 Modelling Sport Specific Performance

HOW WINNING TEAMS KICK FOR SUCCESS IN RUGBY UNION: A BIG DATA APPROACH

SCOTT, G.A., BEZODIS, N.E., BENNETT, M., CHURCH, S., WALDRON, M., KILDUFF, L.P., BROWN, M.R.

SWANSEA UNIVERSITY

INTRODUCTION: Studies within Rugby Union have repeatedly identified kicking as a key indicator of success (1,2), yet no further analysis has been completed to quantify why. While it has been demonstrated that out-kicking your opposition is strategically important, a greater contextual understanding is required to allow deployment of actionable interventions to promote improved outcomes. Given this, the aims of this study were i) to profile the kicks taken during a season of the United Rugby Championship and ii) to quantify whether these kicks differed between winning and losing teams.

METHODS: Coded video analysis files were downloaded from 144 matches within the 2021-22 season of the United Rugby Championship. Sequences containing kicks were isolated and the kicks in each sequence collected (n=6587). For each kick, the type was identified, and allocated to one of five zones across the field. The proportion of kick type and kicks taken in each zone was recorded across the full dataset and then divided into winning and losing team kicks, according to match outcome. The outcome of each sequence was obtained and defined a positive, negative, and neutral outcome. The proportion of positive outcomes were compared between winners and losers within each kick type and zone using Chi-Squared test of association. The rate per sequence of actions made within kicking sequences were calculated for winning and losing teams and compared using two sample Poisson test.

RESULTS: Winning teams kicked more than losing teams in all zones of the field and all kick types. However, both teams had a similar distribution across the field and by kick type, proportional to their total number of kicks. Winning teams had significantly higher percentage of positive sequences outcomes when they kicked from their opposition 10-22m (38% vs. 31%) and their own 10-22m zones (43% vs. 32%). Winners also had significantly higher positive sequences outcomes when completing bomb (51% vs. 38%), territorial (38% vs. 33%) and low kicks (42% vs. 32%). Successful teams also recorded a higher rate of attacking qualities, alongside their use of different kick types and in different zones.

CONCLUSION: Winning teams implement effective kicking strategies in both their own half and opposition half, suggesting that both attacking and defensive kicking styles are required for winning outcomes. Territorial kicks were identified as important to winning sides, alongside bomb and low kicks, suggesting that a combination of both longer, territorial kicks and shorter, contestable kicks can be utilised to promote positive outcomes. The rate at which teams perform attacking qualities, such as completing line breaks, was also important for winning, highlighting the importance of the actions of surrounding players prior, during and after the kicks to support positive sequence outcomes.

FACTORS INFLUENCING IN-GAME PLAYER ACTIVITY IN RUGBY LEAGUE: A NEW APPROACH

WATSON, N., DURBACH, I., HENDRICKS, S.H., STEWART, T.J., JONES, B., DALTON-BARRON, N., WEAVING, D.

UNIVERSITY OF CAPE TOWN

INTRODUCTION: Player activity and load profiling are important in training and management decisions to optimise performance in rugby league. Player movement is a complex phenomenon, involving both spatial (place on field) and temporal (time in match) dimensions. Current approaches to activity profiling typically rely on univariate measures derived from distance-based variables collated from GPS data to classify profiles and player movement with user-defined numeric thresholds, where the metrics used are often aggregated to one observation per match.

These approaches have yielded useful insights into player activity profiles in rugby league and other sports. However, two important research areas are less amenable to analysis with this approach: (i) Investigating the influence of in-game events on player movement (e.g., do activity states change following a try?), and (ii) Combining different dimensions of player activity (e.g., speed, directionality, and acceleration) when constructing activity profiles.

The aim of this study was to introduce Hidden Markov Models (HMMs) - a flexible, data-driven, and statistically robust approach capable of modelling the complexity of player movement. We applied HMMs to both rugby league training and match GPS data to address these two research questions and thus provide valuable tactical and player management decision support.

METHODS: We fitted several HMMs to 1000 rugby league player training GPS files across five training modalities and 215 match GPS files across 35 matches of one team from the 2018 and 2019 English super league competitions. Activity states were constructed jointly from player speed, direction and PlayerLoad data. We investigated the effect of both elapsed time and score difference on the probability of being in or transitioning between different states of activity in a match context. We also compared the activity and load profiles between training modalities and between training and matches.

RESULTS: The HMMs successfully combined multiple movement variables to detect different activity states for both training and match data, and to reveal the probability of being in these states as a function of the two time-varying covariates. Players were more likely to engage in directed, high speed movement as well as very undirected, slow movement at the beginning of a match and when behind on the scoreboard. There are some key differences in activity profiles within training modalities and between training and matches, notably a high-activity training state rarely accessed by players during matches.

CONCLUSION: HMMs are capable of modelling the complexity of player movement in rugby league and can be used to investigate the influence of in-game, time-varying factors on player movement as well as several other research questions of interest. HMMs therefore offer a statistically robust method to profile player activity data that can provide decision support for optimal performance in rugby league as well as several other sports.

SCORING PERFORMANCE OF THE THREE PHASES IN TABLE TENNIS

CHANG, M.H., LIU, Y.T.

NATIONAL TAIWAN NORMAL UNIVERSITY

INTRODUCTION: Table tennis is a fast-paced sport where the serve-attack and the service-return-attack have been considered the most important and effective scoring tactics. The 'three-phase evaluation method' has been developed to analyze table tennis match performance based on three key phases: the attack after service, the service-return with attack, and the stalemate phase. The method combined with other variables such as stroke type and ball bouncing area have usually been used to analyze the techniques and tactics of the individual players. There has been evidence to support that the impact of the serve and subsequent attack on the rally outcome decreases as the number of strokes increases (1). This study aimed to use a revised three-phase evaluation method to analyze the scoring performance of elite mens singles matches in relation to the outcome of the matches.

METHODS: The notational analysis was applied to analyze seven mens singles matches from the quarter-finals to the finals in the 2022 World WTT Cup Finals Xinxiang. Every point in a game was assigned to one of three phases: scored at stroke 1 and 3 of the rally for the service phase, scored at stroke 2 and 4 of the rally or the service-return phase, and scored at stroke 5 or later for the stalemate phase. The scoring rates of each phase were calculated by dividing the total points won in that phase by the total number of services, service-returns, or 5 or longer rallies, respectively. The 3 (phase) × 2 (outcome) repeated measure ANOVA was used to analyze the scoring rates.

RESULTS: The effect of phase was significant, $F(2, 12) = 31.38$, $p < .001$; the post hoc paired comparisons showed that the stalemate phase had significantly higher scoring rate than the other 2 phases (ps< .001). In addition, the winners also had significantly higher scoring rate than the losers, $F(1, 6) = 22.03$, $p < .01$. No significant interaction effect was found.

CONCLUSION: The stalemate phase had the highest scoring rate over the three phases. This indicates that more points were determined later in the rally rather than from the service or service-return attack tactics. Service and service-return both are important techniques and tactics in table tennis, but the result of the analysis suggests that developing tactics for stalemate phase may be the key to winning the table tennis matches.

AUTOMATIC QUANTIFICATION OF DISPLACEMENT AND RING GENERALSHIP DURING HIGH-LEVEL ELITE BOXING COMPETITIONS.

SCHORTGEN, A., GOYALLON, T., REVERET, L., MOUSSA, I., SAULIERE, G., BREZEPHIN, L.

INRIA - LJK, IRMES - INSEP - UNIVERSITÉ DE PARIS, FÉDERATION FRANCAISE DE BOXE

INTRODUCTION: Keywords : Boxing Performance, Video Analysis, Performance Analysis, Ring Generalship

Ring generalship (RG), or ring occupancy, is an essential key performance indicator in elite boxing. Understanding position and movement of an opponent leads to defining better strategies, controlling the pace of the bout and imposing advantageous fighting ranges [1]. In addition to landed strikes, effective pressure and defense, RG influences the final score. Due to the high-intensity nature of boxing, fatigue is directly related to punch effectiveness as well as stances, even if the latter

is significantly less studied in the literature. To date, little has been made available to measure and analyze the concept of RG in real-life scenarios, especially using automatic method to avoid any bias. The purpose of this study is to accurately track fighters locations inside the ring and extract relevant metrics.

METHODS: Based on a single video camera, we automatically capture 2D position of each athlete onto the ring plane during a live combat. A tracking-by-detection algorithm [2] is first trained on a short sub-sample of the fight to detect unique boxers in the scene. The resulting classification allows to build a data-set specific to the bout (context, outfits, lighting). These specific features are used to retrain a multi-person detection algorithm [3]. By combining athlete detection and 2D keypoints estimation, we map features in an image coordinate system. Athletes positions with respect to the ring plane are derived from the feet joint locations and expressed in a metric world reference system through homographic transformation.

RESULTS: 32 fights (3 rounds × 3 min) were studied with this method during a French elite national competition with the collaboration of the French Boxing Federation. During the event, 33 fighters (18 women, 15 men) competed, they traveled an average of 155 m ± 28 per round. The average distance maintained between boxers was 1.23 m ± 0.16. Our study addresses performance indicators such the distance covered by each athlete, heatmaps of the boxing activity, combat profiles (clinch phases, distances ...) and orientation of the fight in relation to the judges.

CONCLUSION: In order to quantify RG during elite boxing combats, we proposed a suitable approach that required simple equipment for use in the wild. With only 96 rounds processed, more fights need to be collected to address the correlations between the metrics investigated in this study. During this event, all landed punches (15464 hits) were annotated by experts and will allow a more in-depth analysis in combination with our tracking data.

QUANTIFYING AND CHARACTERIZING PUNCHES IN ELITE BOXING MATCHES DURING AN OFFICIAL COMPETITION

SAULIERE, G.1, SCHORTGEN, A.1.2, GOYALLON, T.2, REVERET, L.2, FRUCHARD, B.2, LEROY, P.2, BREZEPHIN, L.3

1.IRMES - INSEP - UNIVERSITÉ DE PARIS, 2.INRIA - LJK - LOKI - ZENITH, 3.FÉDERATION FRANCAISE DE BOXE

INTRODUCTION: Quantifying and characterizing punches in boxing fights enables profiling athletes and study winning strategies [1]. Producing this data requires analyzing videos to detect punches and further characterize them. Automatically detecting punches from videos remains challenging, leaving this task to a tedious manual annotation. In collaboration with the French Federation for Boxing (FFB) in the context of an official competition, accelerometers from Inertial Measurement Units (IMU) strapped in the gloves have been tested to efficiently detect punches.

METHODS: FFB officers equipped every athlete with wireless IMU (Xsens Awinda, 120 Hz) before every fights. IMU were strapped on the distal part of the forearms at each hand, and protected under gloves. Punches were automatically identified as peaks detected in the acceleration. IMU were synchronized with high-resolution videos (Qualisys Miqus Video, HD 60 fps) to produce short sequences of animated images representing each punch. A manual annotation tool of these sequences was provided to video analysts of the FFB for the characterization of punches. Punches trajectories were labelled as miss", hit or blocked. Logistic regression analysis is used for establishing the potential associations between the fight result and the number of blocked, missed and hit punches.

RESULTS: A total of 21.474 punches over 94 × 3 minutes rounds (31 matches of 3 rounds, one match lasted 1 round only) has been detected. Analysts excluded 25.09% of false positives. We present results with respect to two different aspect: the efficiency of the annotation task and the athlete productions. Characterizing a punch required in average 7.16s [7.09, 7.23] (95% confidence intervals) for 11 annotators. We observed in average 144 [134, 154] punches towards the head and 22 [20, 24] towards the torso per round, with an average of respectively 56 [51, 62] and 13 [12, 15] successful hits, which agrees with results from the literature [2]. In the logistic regression, fight result is found to be significantly associated with both number of missed ({p}value < 0.001 , OR = 0.97 (0.94, 0.98)) and hit (pvalue = 0.002, OR = 1.03 (1.01, 1.05)) punches but not with blocked punches (pvalue = 0.913, OR = 1.00 (0.98, 1.09)).

CONCLUSION: Instrumenting boxers with IMU enables automatically identifying punches, saving precious manual annotation time that analysts can leverage to solely characterize hits. Better punch identification algorithms should likely reduce false-positives and save even more time. All characterization were performed over an accumulated time of 37.05 hours.

OP-PN24 Nutrition I

PERCEPTIONS AND PRACTICES REGARDING DIETARY SUPPLEMENTS OF NUTRITIONISTS WORKING WITH ELITE SOCCER CLUBS

OLIVEIRA, C.B.1,2, ABREU, R.2, BRITO, J.2, TEIXEIRA, V.H.3,4,5

1. NMS|FCM-UNL; 2. PORTUGUESE FOOTBALL FEDERATION; 3. FCNAUP; 4. CIAFEL-FADEUP; 5. ITR, PORTO

INTRODUCTION: Dietary supplement use is widespread among soccer players. Nutritionists working with soccer clubs play a crucial role in the decision to supplement, and on the types of dietary supplements to recommend and in which situations. However, there is no evidence of their perceptions and practices regarding dietary supplements and the scientific evidence surrounding them. Therefore, this study aimed to assess this issue among nutritionists working with elite soccer clubs.

METHODS: Nutritionists (N=134) working with elite soccer teams from six leagues in Europe (England, France, Germany, Italy, Portugal, and Spain) and Brazil were invited to participate. After ethical approval, practitioners were contacted via e-mail, and professional or personal networks. Data collection ran from 8 November 2022 to 8 February 2023, and used an anonymous online questionnaire with 19 questions, adapted from another used for a similar purpose (1). Overall, 62 nutritionists had responded (46.3% response rate); two refused to participate, and one was excluded due to incorrect fulfilment. Therefore, 59 nutritionists [34.6 (5.6) years] were included in the descriptive statistics analysis presented. Except for age (n=57), data are available for all and expressed in mean (SD) and percentages (%).

RESULTS: Nearly all participants considered themselves knowledgeable and interested in dietary supplements (94.9% responded agree or strongly agree) and reported being often asked about these products (93.2%). Most nutritionists stated consider dietary supplements more effective for enhancing sports' physical and physiological performance (93.2%), fatigue recovery (81.4%), and enhancing sports' cognitive and mental performance (76.3%). The barrier to recommending dietary supplements mentioned by most nutritionists concerned about regulation (50.9%), whereas the enabler was having sufficient training in the area (76.3%) and autonomy to recommend supplements (59.3%). Also, most nutritionists reported wishing to learn more about dietary supplement use for sports performance (66.1%).

Regarding practices, most participants reported being dietary supplement users (57.6%) and recommending supplements regularly (69.5%). Obtaining information from evidence databases and academic journals (93.2%) and conferences (59.3%) were the sources stated by most nutritionists. Finally, some nutritionists reported selling dietary supplements (15.3%).

CONCLUSION: Participants considered themselves knowledgeable and showed a great interest in learning about dietary supplements while also revealing caution about recommending supplement use. Nutritionists reported seeing these products as most effective for enhancing sports' physical and physiological performance, and having sufficient training was the main enabler for recommending supplement use. These findings provide novelty data and open new perspectives for research into supplement use in soccer.

REVIEW OF FOOD PROVISION FOR ATHLETES COMPETING AT THE TOKYO 2020 OLYMPIC AND PARALYMPIC GAMES

PELLY, F.1, DUFOUR, A.1,2, TWEEDIE, J.1, SLATER, G.1

1. UNIVERSITY OF THE SUNSHINE COAST 2. CANADIAN OLYMPIC COMMITTEE

INTRODUCTION: Teams that are competing at the Olympic and Paralympic Games (OPG) rely on food provided onsite at athletes' villages and at competition venues. Evidence has demonstrated that despite advance planning, food provided at these events does not adequately meet the needs of all athletes (1). Furthermore, restrictions have been placed on large scale catering with the advent of COVID-19 (2). The aim of this study was to review the proposed food provision for the Tokyo 2020 OPG in 2019 before COVID-19 and compare to the onsite delivery in 2021 during COVID-19.

METHODS: A previously developed survey (1) was distributed to nine sport nutrition experts on two occasions during 2019 to review the on-paper menu for the Tokyo 2020 OPG. This was followed by an onsite review of food provision by 18 sports nutrition practitioners appointed to national teams during the delayed Tokyo OPG in 2021.

RESULTS: Results demonstrated a significantly higher mean rating (1 = not suitable to 10 = very suitable) for the suitability of the main village menu on site (8.0) in comparison to the initial paper review (7.0; p=0.037). There was a negative correlation between sports nutrition practitioner experience (r = -0.479; P=0.009) and menu rating. Areas that were rated significantly better in terms of availability and acceptability on site than the 2019 paper review included pizza, fruit, yoghurt and food appropriate to make weight. Provision of breakfast cereal and muesli, vegetarian/vegan and snack/ sports foods were rated the worse by experts in 2021, with a rating of 'poor' for the ability to request specific items on the menu. No significant differences were evident between the main village food and satellite villages and venues from the onsite 2021 review, however specific areas such as meeting food allergies, cultural diversity and vegetarian/ vegan items were rated as 'poor' in locations outside the village.

CONCLUSION: This is the first time that the food provision on site has been rated higher by experts than the proposed menu in advance of the event. Changes in food delivery due to COVID-19, including restricted numbers through the dining hall and fast turnover time of food, as well as a longer lead in time may have resulted in improved catering processes. Unlike in previous events (3), budgetary constraints, planning and procurement issues did not appear to be a limitation to appropriate food provision.

THE COMPLIANCE TO COVID-19 FOOD SERVICE SAFETY GUIDELINES BY CATERERS AT THE TOKYO 2020 SUMMER AND BEIJING 2022 WINTER OLYMPIC AND PARALYMPIC GAMES

DUFOUR, A.C., PELLY, F.E., TWEEDIE, J., WRIGHT, H.H.

UNIVERSITY OF THE SUNSHINE COAST

INTRODUCTION: Catering for athletes competing at international sporting events such as Olympic and Paralympic Games (OPG) is challenging. This has been heightened during COVID-19 due to the need for caterers to adapt to new food service guidelines (1), such as those suggested by the International Olympic Committee (2). The purpose of this research was to compare the compliance of caterers to various COVID-19 counter measures (CCM) placed on food provision at the Tokyo 2020 and Beijing 2022 OPG. These included provisions around personal hygiene, sanitization, and physical distancing with the aim of reducing athletes' risk of infection.

METHODS: An online survey was distributed to expert dietitians attending July 2021 Tokyo (n=20) and February 2022 Beijing OPG (n=7). Eleven different CCM were included in the survey for the main dining halls (MDH) in the athlete villages, satellite villages, and venues at both events. The CCM were observed by experts and rated as compliant (100%), partially compliant (50%) or non-compliant (0%) over the course of the event.

RESULTS: Overall, the MDH at both Tokyo and Beijing had higher compliance on CCM than other dining sites. In Tokyo, most CCM were rated as partially or fully compliant, with the exception of reduced seating time with 40% (6/15) experts rating this as non-compliant. Greater than 80% of experts (12 /15) rated full compliance for hand sanitizer, gloves, masks, and plexiglass dividers. Similarly in Beijing's 3 villages, greater than 80% of experts rated full compliance for hand sanitizer, gloves, masks, plexi-glass dividers on seating and regular wiping of seats. In Tokyo satellite villages, experts reported only partial compliance (4/5; 80%) for sanitization of condiments and no or partial compliance (4/5; 80%) for self-service. At venues, 90% (10/11) experts reported full or partial compliance to reduced seating and mask wearing (9/9; 100%) but observed non-compliance to social distancing and eating outdoors. Comments from experts suggested that CCM compliance was reasonable at both events. In Tokyo, however, the MDH was overcrowded at peak times, while in Beijing other aspects of food safety were considered as less rigorous, with two comments about gastrointestinal distress from potential cross contamination in some athletes.

CONCLUSION: Findings suggest that the greater the number of diners relative to the size and flow of the dining area, the more challenging it is for caterers to adhere to CCM. Caterers also must consider all factors affecting food safety in terms of decreasing risk of illness in the dining environment of the Olympic and Paralympic Games.

EFFECT OF SUPERVISED NUTRITION EDUCATION PROGRAMME ON ELITE ATHLETES DURING PREPARATION OF MAJOR GAMES

HAN, Q.1, AN, N.1, SHAO, J.1, WANG, Q.1, ZHANG, M.2

1, NATIONAL INSTITUTE OF SPORTS MEDICINE, 2 WINTER SPORTS MANAGEMENT CENTER OF THE GENERAL ADMINISTRATION OF SPORT OF CHINA

INTRODUCTION: Nutritional strategy and characteristics are largely varied between different sports and even between teammates in accordance to their individualized nutritional goals and competition plan. Furthermore, for those return-to-play athletes who need dietary aims to meet their specific needs, sports nutritionist and dietitian can play a vital role for athletes' professional career and for their exercise performance. As early as 2003, IOC issued its global consensus on sports nutrition 2003: new guidelines for nutrition for athlete, which primarily demonstrated that the amount, composition, and timing of food. And in this programme, we majorly adopted the education slides and lectures based on the well recognized IOC consensus.

METHODS: In this prospective nutrition study, sports nutrition education were conducted with 20 professional elite athletes at the baseline. Nutrition surveys were provided for four months throughout the study. Energy expenditure were estimated

using a strong evidence proved HRV exercise training load monitoring system (Switzerland) and PAL reporting method. DEXA was used for monitoring body composition. Blood biochemistry profile was measured along with the education programme including CK, BUN, Testosterone, and Cortisol for exercise fatigue. Training load was calculated according to routine training including warm-up, strength conditioning, active stretching, and sport-discipline specific training.

RESULTS: The largest need of nutrition is to achieve their ideally optimal body composition and to achieve quick recovery from intense exercise training. After education on foods choices, nutrition survey indicates athletes prefer to choose low fat foods than before supervision. Their bodyweight became lower by the end of major Game season. And the average weight loss was 1.49 kg for ladies and 1.68 kg for men throughout entire season (both P-values$<$0.05). We also found that Fat% and BMI of female athletes were significantly decreased after four months of the intervene, meanwhile, their muscle mass and lean mass increased significantly (both P-values$<$0.05). While, in male participants, we only found significantly increased muscle mass (P-value$<$0.05), though the improvement of Fat% and BMI were observed from the baseline, the change was not significant (both P-values$>$0.05).

CONCLUSION: With nutrition education and supervision, elite athletes prefer to choose healthy foods for achieving optimal body composition and quick recovery purposes. Nutrition supervision under professional dietitian is of great value for optimal exercise performance especially during the preparation for major sport games.

WADA MONITORING PROGRAM SUBSTANCES-CONTAINING DIETARY SUPPLEMENTS MIGHT CAUSE UNINTENTIONAL DOPING OR HEALTH RISK

SZILÁGYI-UTCZÁS, M., PALINKÁS, Z.

HUNGARIAN UNIVERSITY OF SPORTS SCIENCE

INTRODUCTION: The World Anti-Doping Agency (WADA) issues the monitoring program annually. The substances in monitoring program are not prohibited, but they are monitored by WADA in order to detect potential patterns of misuse in sport. Many top athletes try to find "legal" performance enhancer products, especially containing these not prohibited substances (PSs), but instead of being safer, their use can provide high risk to a positive doping test. On the one hand, these ingredients can be expensive, thus to reduce the production costs in many cases they are omitted or substituted with other compounds. On the other hand, in several cases these DS are produced in illegal pharmaceutical industries without any quality control, thus contamination of DS with PS might occur. The detection of PSs by the WADA in DSs used by athletes is a crucial preventive step to avoid unintentional doping. Measurement of active compounds can help also in the evaluation of the cost/benefit of the usage of DSs.

METHODS: The analyses of DS containing active compounds present on the WADA monitoring list were carried out by means of suitable chromatographic techniques (liquid or gas) coupled to tandem mass spectrometry (LC- or GC-MS/MS). Our scopes were to quantify the legal active substances (ecdysterone (ECD), caffeine (CAF), synephrine (SYN), bemethyl (BEM)) and to detect eventual PSs (115 mostly occurring anabolic androgen steroids (AASs), stimulants, narcotics, diuretics, hormones and metabolic modulators). Our analytical methods were optimized to obtain the lowest possible limit of detection (0.6-500 ng/g or mL) of PSs.

RESULTS: Among the different analysed samples (14 ECD-containing DS; 30 CAF- and/or SYN-containing DS, 1 BEM-containing DS) more than 30% of them contained almost one PS, mainly AASs and stimulants, in the concentration range from ng/g to µg/g. At the same time in many cases the measured content of the active substances was not in accordance with that on the label. In the case of CAF-containing products 20% were contaminated with PSs, while only in half of them was the CAF content in the range of ±10% respect to the labelled values. In one pre-workout product the measured caffeine content was double as labelled, resulting in 597 mg/dose quantity, which can cause serious health issues for non-habitual CAF consumers. Totally, 14 different ECD-containing DSs from 9 brands were analysed. In all cases the measured ECD content was much lower that on the label. In addition, 25% of the samples contained PS. Concentration of the active compound and contaminations varied from batch to batch randomly. BEM-containing DS contained 3 different selective androgen receptor modulators and 1 stimulant in the concentration of µg/g.

CONCLUSION: Serious discrepancies were explored on the labelling of program substances-containing supplements, including lack of active compounds and presence of PS. The developed methods provide outstanding support for athletes regarding DS safety.

OP-SH23 Sociology (mixed)

PHYSICAL EXERCISES OF CHINESE OLDER ADULTS AND SOCIAL PARTICIPATION: HEALTH PROMOTION AND NETWORK EXPANSION

FUBAIHUI, W.

CHINA INSTITUTE OF SPORT SCIENCE

Introduction

There is a logical relationship among physical exercise, health level and social participation of the elderly, but the research on the influence of physical exercise on social participation of the elderly in China is relatively lacking. Physical exercise will improve peoples health and expand the social network of the elderly. The changes of these factors may promote the elderly to actively participate in society from different aspects such as ability, willingness and ways. In order to effectively promote the social participation of the elderly through physical exercise, it is necessary to investigate the intermediary role of subjective and objective health of the elderly.

Methods

Using data from China Longitudinal Aging Social Survey conducted in 2016, we perform binary logistic regression model to analyze the relationship between physical exercises and social participation of Chinese older adults. The structural equation modeling is used to estimate the mediating effects of subjective and objective health. The mediating effect of subjective and objective health was examined by Sobel test, and the moderating effect of urban-rural heterogeneity and age marriage was also analyzed.

Results

This paper studies the mechanism of physical exercise (integrating the information of participation, frequency and the intensity of each exercise) on the social participation of the elderly, and tests the intermediary role of health factors in the relationship between them.

Discussion

Results suggest that regular physical exercise will significantly enhance the increase the probability of older adults' social participation.; physical exercises affect social participation in both direct and indirect ways through health. The direct effect is embodied in that physical exercise expands the social network of the elderly and enhances the degree of socialization, thus improving the enthusiasm of the elderly for social participation; the indirect effect is realized by improving the health level of the elderly, and subjective and objective health plays an intermediary role. Participating in exercise can not only improve the objective health status, but also have the ability and conditions to participate in economic, political and voluntary activities. It can also improve the subjective health status of the elderly and make them more willing to participate in various forms of society. There are internal differences in the promotion of physical exercise to the social participation of the elderly. For the rural elderly, the very old and the elderly without spouses, improving the participation of physical exercise will bring more obvious spillover social effects and significantly improve their social participation level. This paper further confirms the positive social effects of physical exercise on the elderly, and provides a theoretical basis and a case study of China for promoting the integrated development of physical education and old-age care.

THE INFLUENCE OF SPORT CLIMBING JOINING THE OLYMPIC GAMES ON THE FINANCIAL SITUATION OF THE INTERNATIONAL FEDERATION OF SPORT CLIMBING AND ITS IMPLICATIONS

LIU, Y.D., LIU, L.H.

CHINA UNIVERSITY OF GEOSCIENCES, WUHAN

Introduction

Organizational change is an important factor affecting its development. The International Federation of Sport Climbing (IFSC) contributes to the sustainable and healthy development of sport climbing and further expands the influence of sport climbing in the Olympic Games. For such a non-profit organization, good financial management is an important material basis for its long-term healthy development. Therefore, it is necessary to systematically study the economic situation of the IFSC after the entry of sport climbing into the Olympic Games, which is not only of great guiding value to the guarantee of healthy growth of the IFSC, but also of positive reference value to other international sports associations, especially for those which are looking for the entry into the Olympic Games.

Methods

This study uses a variety of non-profit sports organization financial status analysis methods such as literature research, comparison analysis, trend analysis and gray relational analysis to comprehensively and systematically investigate the financial situations based on the published financial statements on the official website of the IFSC from 2015 to 2019. This study mainly focuses on the variation trend of its financial situation before and after the sport climbing joining the Olympic Games and makes a comparative analysis.

Conclusions

(1)The total assets of the IFSC significantly increase after the successful entry of sport climbing into the Olympic Games. The entry of sport climbing into the Olympic Games has played a positive role in promoting the funds of the IFSC.

(2)The successful entry of sport climbing into the Olympic Games has stimulated the vitality of the liquidity of the IFSC, enhanced the asset elasticity, improved the speed of fund turnover, avoided the insufficient fund in the operation process, which are conducive to the long-term and healthy development of the IFSC.

(3)The successful entry of sport climbing into the Olympic Games has increased the liabilities of the IFSC, which may reduce the financial elasticity and make the cash flow insufficient to support the normal operation of the organization. However, based on the results of gray relation analysis, the subsequent impact of solvency on the finance of the IFSC tends to be stable.

(4)The financial revenue and expenditure of the IFSC is balanced, which demonstrates the organization is in good condition. However, the gray relation analysis results show that the balance relationship between revenue and expenditure has

a high impact on the financial status of the IFSC, and the organization should pay attention to maintaining a good balance relationship between revenue and expenditure to stabilize the overall financial status.

TRANSFORMING EQUESTRIAN SPORTS TO A MORE ENVIRONMENTALLY JUST ACTIVITY

THORELL, G., HEDENBORG, S., RADMANN, A., ANDERSSON, P., BEAMES, S.
THE SWEDISH NATIONAL EQUESTRIAN CENTRE AT STRÖMSHOLM AND KARLSTAD UNIVERSITY

Introduction

While the equine sector in Sweden and Norway provide leisure activities, entertainment and employment for many people of all ages, these come with associated negative effects. The equine sector is cast as a 'climate villain' that emits more carbon dioxide than domestic aviation. It is concluded that while research is scarce, feed and transport are serious threats to the environment. Similar conclusions are found in other studies on the environmental impact caused by the equine sector, which show how nutrient leakage from manure piles, paddocks and pastures is a major problem, alongside the aforementioned issues of feed and transport. This study aims to understand the decision-making processes and actions taken by actors in equestrian sports to transform the sport into a more environmentally just activity. The project is informed by two framing theoretical perspectives: institutional economic theory and directional transformation (North, 1990; Scoones et al 2015).

Methods

Data consists of 30 semistructured interviews. These have been analyzed using thematic content analysis.

Results

Results point to the following challenges in transforming equestrian sports into a more environmentally just activity: providing sporting activities with animals, organizational frameworks, economy, transport, location, knowledge, horse welfare, time and consumption. Suggested solutions are connected to behavior change.

Discussion

Institutional theory sheds light on how change is hindered by institutions and norms. Equestrian sports face challenges in relation to transforming to more sustainable sports. Some of these challenges are shared with other sports (such as people's logic for participating in sports, cf., Larneby et al 2022), while others are connected to a specific 'stable culture' (cf., Thorell et al 2015) in which equestrian sports is seen as dependent on, for example, carbon dioxide emissions and consumption patterns. In the project's next phase, workshops will be conducted to find solutions together with collaborative partners in the sport.

IS-AP02 Supporting female athletes through pregnancy and postpartum

INITIATING THE MOTHER-ATHLETE ROLE: DILEMMAS AND OPPORTUNITIES

MCGAWLEY, K.
MID SWEDEN UNIVERSITY

Womens participation in competitive sport has increased markedly over the last century. At the first Winter Olympics in Chamonix in 1924 only 4% of the competitors were women. 98 years later, at the 2022 Beijing Winter Olympics, female participation had reached 45%. This significant rise in representation has been accompanied by a development in the professionalisation of womens sport. Nevertheless, sporting opportunities and incentives remain unequal between the sexes, with social, cultural and economic factors continuing to hinder women to a greater extent than their male counterparts. As such, continued efforts are needed to provide female athletes with the tools they need to develop and succeed in sport.

Motherhood is distinct from fatherhood in that women undergo pregnancy, childbirth and postpartum recovery. While women and men may have an equal desire and commitment to start a family, the immediate consequences have a far greater impact on women. The effects of motherhood are exacerbated in elite sporting contexts, due to the physicality of

athletic endeavours and the inability of women to compete during certain time periods. Despite these distinct challenges, relatively little is known and communicated about how to facilitate female athletes through pregnancy and postpartum.

Several studies across different sports and a range of countries have identified recurring dilemmas facing sportswomen as they initiate, maintain and/or discontinue the mother-athlete role. In a recent study conducted with elite Scandinavian endurance athletes, we identified four such themes: Biological clock versus peak performance; Maintaining fitness versus training safely; Receiving support versus facing deselection; Balancing competing mother-athlete demands. Many of the participating athletes felt pressured into prioritising either athletic excellence or motherhood, particularly in their early to mid-thirties. Further, maintaining fitness and training safely during pregnancy was perceived as a challenge, as was balancing the mother-athlete role after childbirth. In many cases athletes felt uncertain about the support they may or may not receive from their team or federation and there were perceptions of incompatibility surrounding the mother-athlete role.

With a growing number of studies uncovering similar issues, it is clear that greater efforts are needed to promote mother-athlete-specific knowledge and provide policies to support female athletes. These are vital future steps towards greater equality, the prolongation of athletic careers and enhanced wellbeing for elite female athletes. In this lecture, Dr. Kerry McGawley will delve into the existing research that has investigated the challenges and dilemmas experienced by mother-athletes and will further highlight opportunities for future development in research and practice.

RAISING THE BAR: EXERCISE RECOMMENDATIONS FOR PREGNANT ATHLETES

DAVENPORT, M.

UNIVERSITY OF ALBERTA

Over the last decade, elite athletes have begun to challenge stereotypes regarding participation in performance sport during pregnancy. From marathon runner Paula Radcliffe to tennis star Serena Williams, and most recently sprinter Allyson Felix, female athletes are pushing back against the societal narrative that they should "take it easy" during pregnancy. Although extensive literature supports the safety and benefits of prenatal exercise, these data are primarily limited to the general obstetric population. Current exercise guidelines outline 150 minutes of moderate-intensity physical activity each week. However, these conservative recommendations do not serve elite athletes who substantially exceed this advice during training. Several studies demonstrate that sport and exercise participation declines in pregnant athletes due, at least in part, to a lack of research and policy in this area.

Pregnancy is a period of profound physiological and psychological adaptation to support the growing foetus. Although early recommendations cautioned against exercise during pregnancy, over the last decade we have had a transformational shift in our view of physical activity and exercise away from an activity that is "nice to do" to a prescription for enhanced health for both mother and baby. Yet, prenatal exercise is fraught with numerous myths and misconceptions, especially for recreational and elite athletes. In this lecture, Dr. Davenport will provide an overview of current global guidelines for prenatal exercise (including recommendations, screening tools and contraindications to exercise), and describe how physiological adaptations to pregnancy impact exercise prescription. She will also present novel data and considerations specific to the pregnant athlete, including heavy weightlifting, HIIT, Valsalva and supine exercise. This lecture will be designed to be relevant to the practitioner and researcher, as well as coaches and athletes.

MAKING IT WORK: A CASE STUDY OF AN ELITE ATHLETE NAVIGATING HER WAY THROUGH PREGNANCY AND RETURN TO SPORT POSTPARTUM

HAYMAN, M.

CENTRAL QUEENSLAND UNIVERSITY

Historically, motherhood signalled the end of an elite athlete's career. However, we are now witnessing a shift away from motherhood and being an athlete as two mutually exclusive periods in time, to an increasing number of elite female athletes wanting motherhood to be a part of their athletic journey. Although the exact numbers of elite female athletes who become pregnant and return to sport postpartum is not known, research suggests pregnancy and childbirth within high-performance sport is an increasing phenomenon with more athletes choosing to continue their training during pregnancy and return to sport and competition postpartum.

Despite this phenomenon, there remains a paucity of literature examining the exercise behaviours of elite athletes during pregnancy, and the maternal and foetal outcomes of athletes who exceed exercise during pregnancy recommendations. Of the literature that does exist, much of the data has been subjectively collected via qualitative approaches. Only two studies to date provide quantitative insight into the training and exercise characteristics of elite athletes during pregnancy, one that involved a sherpa and the other a cross-country skier, both of which adopted a longitudinal observational methodological approach.

Longitudinal observational case studies represent a practical and ethically defensible manner to examine the exercise behaviours among elite athletes during pregnancy, particularly in women who are already active and intend to remain highly active during pregnancy. As such, Associate Professor Melanie Hayman will present novel data from an ongoing case study of a sprint kayaker navigating her way through pregnancy and return to sport postpartum as an elite athlete.

Invited symposia

IS-BM03 Muscle shape change and 3-D fascicle behaviour in skeletal muscles: An emerging picture of dynamic muscle contraction

DETERMINANTS AND MECHANICAL CONSEQUENCES OF SKELETAL MUSCLE SHAPE CHANGE

ROSS, S.
SIMON FRASER UNIVERSITY

Skeletal muscles are the motors that drive movement of the body, from endurance tasks such as long-distance running to explosive activities such as jumping. Most of what we know about whole muscle performance comes from studies on sarcomeres, single fibres, or bundles of fibres. As a result, the complex 3D dimensional deformations of whole muscles are often ignored not only in our understanding of whole muscle performance, but also in how we represent muscles in musculoskeletal models such as OpenSim. When muscles contract and shorten in the longitudinal direction, they must bulge to maintain a nearly constant volume. In pennate muscle, this transverse expansion is accommodated by the fibres rotating to greater angles, which alters a muscle's mechanical output. In this talk, I will discuss the fundamental determinants of skeletal muscle shape change and how they impact output force and mechanical work using simulation results from a 3D continuum model of muscle.

Firstly, I will discuss how and why pennate muscles change shape when they contract and what behavioural consequences this may have for muscle performance. During contraction, energy from ATP hydrolysis is redistributed in muscle tissues as they deform. How the energy and deformations are distributed depends in part on the architecture and geometry of the muscle, which subsequently dictates the energy that is used to move an external load. We simulated isometric contractions of blocks of muscle with different fibre pennation angles and found that the energy stored in the tissue surrounding fibres (primarily extracellular collagen matrix) during contraction was higher in more pennate muscles, which was associated with lower muscle force output despite higher physiological cross-sectional area (PCSA). This suggests that greater pennation angle may have less functional significance for increasing muscle force through increasing PCSA, as is commonly assumed.

Secondly, I will discuss the impact of muscle tissue mass and inertia on muscle performance during cyclic contractions like those seen in leg muscles during walking and running. Muscles are commonly assumed to behave as massless structures in which the tissue mass and internal accelerations are not considered. We simulated cyclic contractions of whole muscle the size of a human medial gastrocnemius and found that accounting for the effects of tissue mass resulted in substantially lower work output. We also found that increasing pennation in mathematical muscle models resulted in smaller reductions in work when accounting for mass. Thus, pennation may be important for reducing the energetic penalty of greater mass in larger muscles such as those in humans.

Finally, I will consider the implications of this greater fundamental understanding of muscle shape change during contraction for sports performance and rehabilitation.

THE EFFECT OF FATIGUE ON SKELETAL MUSCLE GEARING DURING CONCENTRIC AND ECCENTRIC CONTRACTIONS

BLAZEVICH, A.
EDITH COWAN UNIVERSITY

During dynamic muscle contractions, whole-muscle length change results from both fibre length change and rotation. Therefore, muscles can work in a gear >1.0, where muscle length change exceeds fibre length change. The reduced need for fibre length change should profoundly affect fibre, and thus whole muscle, function in accordance with the muscle's force-velocity, force-length, and history dependent properties. In eccentric contractions in particular, the reduced fibre strain for a given muscle length change is speculated to reduce fibre injury risk as well as influence chronic adaptations to repeated exposures (e.g. hypertrophy). Nonetheless, studies of muscle gearing in vivo in humans are still relatively scarce, and little information exists in relation to gearing during eccentric contractions in particular. In one experiment, vastus intermedius fascicle length changes (measured using ultrasonography) were greater during singular (non-consecutive) eccentric than concentric knee extensions, although length changes in vastus lateralis were similar between contraction modes. Such fascicle behaviours may partly explain the greater muscle damage observed in vastus lateralis after bouts of eccentric contractions. However, it is unclear whether such behaviours are observed in other muscles or when consecutive concentric-eccentric contractions are performed. The first aim of this presentation is to present new data from experiments in which we have studied both biceps femoris (long head) and gastrocnemius medialis during dynamic contractions. Data show that fascicle behaviours, and thus gearing, during concentric and eccentric phases were similar under the study conditions, so eccentric contractions appeared to be 'mirror images' of the concentric contractions. Nonetheless, data from research currently underway in which gearing is studied under conditions of different muscle forces and contraction speeds will be presented.

INFLUENCE OF MUSCLE SHAPE CHANGES ON THE METABOLIC AND MECHANICAL DEMANDS OF HUMAN MOVEMENTS

MONTE, A.

UNIVERSITY OF VERONA

Skeletal muscle contraction triggers dynamic changes in muscle shape, with pennate muscles bulging in thickness, width, or both. The direction of shape change mediates the muscles mechanical output (e.g., work and force production). For example, unidirectional transversal (external) muscle loading induced by a plunger influences muscle shape and reduces muscle force, suggesting that compression garments typically used in sports activities as well as pressures exerted by neighbouring muscles may negatively affect muscle force capacity and, thus, muscle performance. Therefore, the first aim of this presentation is to introduce the current state-of-the-art as well as new data describing how factors that reduce the muscles capability to change shape affect muscle contraction and fascicle dynamics. In this regard, using a combination of ultrasound, EMG and dynamometric measurements, we observed that changes in muscle fascicle behaviour imposed by a transversal load could negatively affect muscle force and work production during both maximum and explosive contractions. This impairment in contractile capacity could be partially attributable to an internal deformation imposed by the load, which affects fascicle dynamics during contraction.

Along this line of reasoning, the metabolic demand of contraction should increase for a given mechanical requirement when the muscle is not free to change shape. Consequently, physiological (e.g., ageing), pathological (e.g., dystrophy) and external (e.g., wearing compressive garments) factors that can affect the muscle shape change capacity could affect the metabolic cost of muscle contraction Therefore, the second aim of this presentation is to present new data where the effects of muscle shape change on the metabolic demands of human movements have been evaluated. In particular, I will report data from experiments in which plantar flexor muscle shape changes were manipulated during sub-maximal fixed-end as well as dynamic concentric contractions. For a given muscle force, we observed that external load application reduced the muscles radial expansion and hence reduced fascicle rotation (i.e., changes in pennation angle). Consequently, changes in fascicle length increased as a function of the applied load alongside an increase in muscle EMG activity and the mechanical work produced. These increases, which were needed to sustain the same level of force, increased the metabolic cost of muscle contraction. The results suggest that factors that limit muscle shape changes can affect not only the mechanical but also the metabolic demands of muscle contraction.

In the final part of this talk, I will discuss the implications of these results in daily and sports-related activities.

Oral presentations

OP-AP07 Modelling Endurance Performance

OPTIMAL MODELING AND ANALYSIS OF PACE STRATEGY FOR WOMENS 20KM RACE WALKERS

QIAO, H., YAN, C., TINGGANG, Y.

CHINA INSTITUTE OF SPORT SCIENCE

INTRODUCTION: The results of competitive sports are the comprehensive performance of athletes technical and tactical level, physical fitness and psychology. Race walking can be interpreted as a continuous single-person sport, and the choice of the optimal rest period in the process of continuous exercise will affect the fatigue degree and fatigue relief of athletes and the speed distribution of athletes during the race walking.As a long-distance periodic endurance event, how to effectively control the athletes efforts and reasonably allocate their time to make the race walking performance reach the best under the limit of physical skills is an urgent scientific problem, which can also be equated with the problem of minimizing the time required for athletes to seek to cover a fixed distance in time trial.

METHODS: Based on the fatigue negative utility characteristics of athletes effort distribution, an optimization model of speed distribution strategy during race walking is constructed.The model parameters are fitted by using the collected data of international womens 20km race walking events, and the most effective time effort distribution mode and optimal pace strategy of athletes are verified.

RESULTS: Based on the fatigue negative utility characteristics of athletes effort distribution, the optimization model of speed distribution strategy during race walking is established and solved by establishing the problems of minimizing time, maximizing athletes "output" and minimizing sports cost under the constraints of athletes effort and physical fitness level. On this basis, the model is fitted with the competition data of the worlds outstanding female race walkers, and the "high-low-high" pace strategy is obtained. According to the characteristics of long distance, competition rules and technical requirements, this study establishes three models of the transformation relationship between speed and effort rate.

CONCLUSION: By solving the model, it can be known that the longer the total score time, the shorter the time required for full sprint, because the poor total score does not need to maintain a long full sprint state; At the same time, it is found that for long-distance competitions, athletes should not stay too long in the fatigue growth stage, but should save their physical strength to complete the long-distance race. It is suggested to strengthen the targeted training of pace strategy in the sprint stage of preparing for large-scale events, and pay attention to the choice of coping strategy and pace strategy for the large fluctuation of precipitation probability.

PREDICTING HEART RATE AT LACTATE THRESHOLDS USING MACHINE LEARNING

OUTWIN, J.R.1, CHANG, J.1, DAVIS, F.1, MELVIN, A.C.1, STUMP, O.1, REED, S.1, DEJONG LEMPKE, A.F.1, KOZLOFF, K.M.1,2, LEPLEY, A.S.1

UNIVERSITY OF MICHIGAN

INTRODUCTION: Wearable technology gives users a myriad of training information. Predicted maximum heart rate (HR) is often used to delineate "training zones," but prescribing exercise intensity in this way elicits heterogeneous stimuli [1]. Lactate thresholds have been proposed as a more informative means of prescription [2], but current methods require specialized equipment and training. Utilizing demographic information and HR metrics in machine-learning (ML) models could allow for a more individualized approach to predict HR at these submaximal anchor points.

METHODS: 218 runners of varying experience levels volunteered as part of a larger study, with 188 included in this analysis. A 12-lead ECG collected HR during a graded treadmill exercise test to maximal effort with blood lactate recorded at the end of each 3 min stage. First and second lactate thresholds (LT1, LT2) were identified at 0.5 and 1.5 mmol above baseline. A 30 s average centered around the time point corresponding to each threshold was recorded as threshold HR, and maximum heart rate during the test was recorded as HRmax. HR/workload slope (HRWS) was recorded as the slope of the best-fit line for the HR vs speed plot. A random subset of 125 participants was used to train various linear and ML regression models using gender, age, BMI, HR max, and HRWS. The remaining 63 participants were used to test for model accuracy. Models were compared against current HR guidelines for the lower bound of vigorous and near-maximal exercise intensity domains from the American College of Sports Medicine (ACSM), roughly corresponding to LT1 and LT2.

RESULTS: ACSM guidelines were the least correlated in the training subset (adj. R^2=0.21, 0.25; $p<0.01$) and least predictive in the test subset with mean absolute error (MAE) of 13.8 bpm at LT1 and 15.4 at LT2. Linear regression showed significant, moderate correlations for both LT1 and LT2 in the training subset (adj. R^2=0.53, 0.50; $p<0.01$) as well as reduced prediction MAE at 10.1 and 7.9 bpm. ML models demonstrated lesser fit to the training data with similar predictive accuracy to linear modeling, also outperforming ACSM guidelines (Multi-Layer Perceptron: R^2=0.46, 0.36, MAE=10.3, 7.6 bpm; Support Vector: R^2=0.39, 0.36, MAE=10.1, 7.6 bpm).

CONCLUSION: Regression modeling with demographics and HR metrics demonstrated improved accuracy over current ACSM guidelines in predicting HR at lactate thresholds in a population of runners. This technique could allow for a novel means of providing athletes with easily accessible, individualized, and accurate exercise intensity information through wearable technology. While ML appears capable of identifying useful trends in the data, future research is needed to refine its prediction capabilities.

TOWARD AN INDIVIDUALIZED APPROACH TO COMPARE 1D TIME SERIES

RAO, G.1, AYAD, E.1, JANIN-POTIRON, P.1, DELATTRE, N.2, GUÉGUEN, N.2, PATAKY, T.3

1AIX MARSEILLE UNIV, CNRS, ISM, MARSEILLE, FRANCE; 2MOVEMENT SCIENCES DEPARTMENT, DECATHLON SPORTSLAB RESEARCH AND DEVELOPMENT, VILLENEUVE D'ASCQ, FRANCE; 3DEPARTMENT OF HUMAN HEALTH SCIENCES, KYOTO U

INTRODUCTION: Group-based analysis have long been known to provide valuable information regarding the general behavior of a population but lack the ability to provide reliable and specific conclusions for each individual of the considered population. Several single subject analysis methods have been proposed to better consider the individual level and provide the most appropriate intervention to everyone [1-2]. These existing methods are restricted to 0-dimensional variables, while recently, one-dimensional time series analyses have been proposed at the group-level and proven a very powerful way to assess the influence of various factors (expertise, equipment, pathology…) on behavior [3]. A major limitation of a single-subject experimental procedure is randomization weakness due to a limited number of condition order permutations. The aim of this study was to propose a new statistical procedure, based on the SPM1d framework, to provide 1d single-subject statistical comparisons while taking into account the limitations of randomization.

METHODS: Ten participants ran on a treadmill at a controlled speed for 5 minutes while wearing 4 different pairs of shoes in a randomized order. 3D lower limb joint kinematics were obtained from motion capture data acquired at 300Hz. 150 consecutive cycles were then selected, and kinematics data time-normalized to 101 points for each cycle. From the time stamps of the different experimental conditions and of each cycle, a time-based linear detrending was included in a general linear model based on the spm1d framework. The results from ANOVA procedure testing for the influence of the shoes factor on the joint kinematics with and without the detrending process were compared.

RESULTS: The results of the ANOVA comparisons revealed the individual nature of the adaptations to the experimental conditions. Indeed, some participants exhibited similar ANOVA results with or without the detrending while others revealed dramatically different outputs. For the participants revealing a strong influence of the detrending, the conclusions would have been different (and sometimes opposite) if no detrending was taken into account. This point suggests that detrending should be an important consideration for single-subject analyses.

CONCLUSION: The proposed procedure is a first step in attempting to allow for the statistical comparison of 1d continua in a single-subject experimental design. This new procedure encompasses both a suggestion for a single-subject experi-

mental design and an updated version of the spm1d framework better suited for such sport science oriented experimental designs.

PHYSICAL FITNESS COMPARISON ANALYSIS IN ADOLESCENT ATHLETES USING MACHINE LEARNING : TRACK AND FIELD, FOOTBALL AND SWIMMING

LEE, Y.1, CHANG, J.1, LEE, D.2, LEE, H.1

1. DANKOOK UNIVERSITY, 2. CHUNGNAM NATIONAL UNIVERSITY

INTRODUCTION: Physical fitness (PF) is an important factor in determining the physical condition of an athlete and their athletic performance. The main PF factors such as body composition, strength, flexibility, endurance, and agility can contribute to the differences between various sports . The previous approaches to analyzing PF in athletes have mainly focused on using statistical and machine learning algorithms to predict the injury or performance. However, by focusing on the application of machine learning to PF analysis, it is possible to identify the relative importance of different aspects of PF for different types of athletes and sports.

METHODS: The subjects of this study were 1,267 male adolescent athletes (track & field: 402, football: 537, swimming: 105), and the data of physical fitness measured from September 2018 to October 2019 at the Korea Sports Science Center was used. In total, 15 elements of physical fitness (body fat, body weight, BMI, grip strength (L, R, avg), back muscle strength, push-up, sit-up, standing long jump, sargent jump, side-step, backward flexion, sit & reach, eye-hand coordination) were recorded. Different machine learning algorithms (linear regression, support vector machine, random forest, XGBoost) were evaluated by accuracy, area under the curve, and f1-score, and calculated main PF factors from the SHAP value.

RESULTS: As a result, XGBoost showed the highest performance. Based on XGBoost, accuracy, area under the curve, and F1-score were 0.87 0.84, 0.86 in track & field and football, 0.92, 0.86, 0.87 in track & field and swimming, and 0.91, 0.92, 0.86 in football and swimming, respectively. Furthermore, SHAP value showed that standing long jump in track & field and football, sit & reach in track & field and swimming, and sit-up in football and swimming were the main PF factors.

CONCLUSION: The proposed method will be able to identify the PF characteristics of general adolescent who start exercising and recommend suitable sports type, and it will be possible to develop and present training methods that consider PF factor customized for the sports type in adolescent elite athletes.

FOUR-YEAR LONGITUDINAL ASSESSMENT OF MODIFIABLE AND NON-MODIFIABLE RISK FACTORS FOR BONE STRESS INJURIES IN INTERCOLLEGIATE DISTANCE RUNNERS

KOZLOFF, K., BOWN, M., FANNING, C., DAVIS, F., ROGERS, K., MARTIN, J., PFLUEGER, C., CAREY, G., RIFAT, S., ZERNICKE, R.

UNIVERSITY OF MICHIGAN

INTRODUCTION: Bone stress injuries (BSI: stress fracture/reaction) are the clinical endpoint of mechanical and metabolic events that are prevalent in sports emphasizing leanness, endurance, and skeletal loading. Despite identifying contributions of individual BSI risk factors, translating data into predictive and actionable models of BSI prevention remains elusive. The Female Athlete Triad Risk Assessment Tool [1] was adapted to prospectively identify female [2] and male [3] athletes at high risk for BSI, but doesn't account for modifiable factors such as sleep, which has been associated with BSI in military personnel [4]. The purpose of this study was to evaluate BSI risk in distance runners using the modified Triad assessment tool and to compare risks to those derived from sleep surveys as an independent predictor of BSI.

METHODS: Male and female distance runners from an NCAA D1 Cross Country program were recruited over four years. Prospective BSI risk scores were evaluated using a modification of the Female Athlete Triad Risk Tool [2,3] using preseason surveys and DEXA-derived bone mineral density (BMD) of the hip and spine. Individual scores on a 0-2 pt scale were summed as follows: Prior BSI (none:0 pt; 1 low risk site:1 pt; >1 high risk site or >2 low risk site:2pt); dietary restriction (none:0pt; some/past DE history:1pt; current DE:2pt); body mass index (BMI>18.5: 0pt; BMI 17.5-18.5: 1pt; BMI<17.5: 2pt); and low BMD Z-score (>-1: 0pt; -1 to -2: 1 pt; <-2: 2 pt). Female surveys included age at menarche (<15 yrs: 0pt; 15-16: 1pt; >16: 2pt) and cycles over past year (>9 menses: 0pt; 6 to 9:1 pt; <6: 2pt). Sleep hygiene was assessed by validated sleep instrument [5] pre- and mid-season. Annual BSI incidence was monitored. Surveys were updated annually and subjects were treated independently for each year of enrollment. Relative risk (RR) scores for BSI for any year was compared to BSI incidence for subjects scoring 0-1pts on the modified Triad tool and to subjects registering a change of -1 to +1 points on sleep hygiene.

RESULTS: 41 men and 49 women enrolled with participation ranging between 1-4 yrs. A total of 38 (women) and 14 (men) BSI were observed. Of 194 athlete-seasons of data, 160 included complete assessments. Women scoring 6-7 out of 12 maximal points on the modified Triad tool increased RR of BSI 2.7 fold (95% CI 1.2-5.9, p=0.016). Men scoring 4-5 (out of 8) increased BSI RR 8.2 fold (95% CI 1.4=48, p=0.012). Within-season worsening of sleep hygiene by 4-5 points (17 max) independently increased BSI RR 3.4 fold (95% CI 1.9-6.0, p<0.0001) in women, but not men.

CONCLUSION: Predictive tools that incorporate sleep as a modifiable behavior may be combined with other personalized metrics to help identify athletes at greatest risk for BSI.

OP-AP33 Long Distance Running

THE TRAINING INTENSITY DISTRIBUTION OF 119,747 MARATHON RUNNERS.

MUNIZ-PUMARES, D., HUNTER, B., MEYLER, S., MAUNDER, B., SMYTH, S.
UNIVERSITY OF HERTFORDSHIRE

INTRODUCTION: There is an ongoing debate about the effectiveness of the various training intensity distribution (TID) approaches on endurance performance (1,2). This is, in part, due to the relatively small sample used in studies reporting TID, primarily elite and well-trained athletes, and the lack of consensus surrounding how different training zones are established. Here, we investigated TID strategies prior to a marathon in a large sample of recreational runners, using three training intensity zones demarcated by physiological thresholds.

METHODS: A dataset of 119,747 unique runners who completed 152,160 marathons between 2014 and 2017 was analysed. The dataset contained running activities recorded onto a running platform (Strava®) in the 14 weeks prior to a marathon, excluding the taper phase (herein defined as 3 weeks prior to the marathon). A 3-zone (Z1 to Z3) training model was created for each runner. First, Z3 was defined as intensities above critical speed (CS), which was calculated from the best performance recorded in discrete segments, as described elsewhere (3). Then, Z1 and Z2 were determined as intensities below the lactate threshold (LT), and intensities above the LT but below CS, respectively. The LT was estimated to be 85% of CS, following a meta-analysis of 22 studies reporting both LT and CS. TID was characterised as polarised when time spent in Z1>Z2 and Z3>Z2; pyramidal TID as Z1>Z2 and Z2>Z3; threshold TID as Z2>Z1 and Z2>Z3; and high-intensity interval (HIT) TID as Z3>Z1 and Z3>Z2. Runners were grouped for TID analysis based on their marathon finishing time, in 30-min intervals.

RESULTS: The pyramidal TID was the most common approach for all subgroups. In the fastest runners (marathon time 120-150 min), 82.4% of runners adopted this approach, higher than polarised (8.1%), threshold (5.8%), and HIT (1.8%). Runners in this group completed 66% of their training in Z1, 22% in Z2, and 12% in Z3. As marathon performance decreased, the pyramidal TID remained the most popular approach, but runners adopted more varied TID strategies. A pyramidal TID was adopted by 36.9% of runners with finishing times of 240-270 min, followed by threshold (33.8%), HIT (18.3%), and polarised (11.0%). These runners performed 40% of their training in Z1, 34% in Z2, and 26% in Z3.

CONCLUSION: A pyramidal TID, whereby runners spend most time in Z1 (below the LT) and progressively less time in Z2 (between LT and CS) and Z3 (above CS), was the most common TID approach. This finding was consistent irrespective of marathon performance, but the percentage of runners following a pyramidal TID approach was highest in the fastest runners, and decreased in popularity as marathon performance decreases.

TRAINING FOR OLYMPIC GOLD IN ENDURANCE SPORTS: VIEWS FROM SUCCESSFUL COACHES

SANDBAKK, Ø., BUCHER SANDBAKK, S., TØNNESSEN, E., LOSNEGARD, T., SEILER, S., HAUGEN, T.
NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY

INTRODUCTION: Performance development in endurance sports is determined by a multifaceted interaction of manifold variables, such as training volume, frequency, and intensity distribution. While training practices among world-leading athletes in long-distance running, road cycling and cross-country skiing are extensively explored, best practice training information is limited for many other endurance disciplines such as swimming, biathlon, speed skating, rowing and triathlon. In addition, comparisons of training variables across studies and sports are challenging due to lack of a common methodological framework (e.g., intensity zones) and terminology.

Norway has been one of the world-leading sport nations in the last 2-3 decades, with the majority of Olympic and World Championships medals won in endurance sports. One of the advantages of the Norwegian system is that all endurance sports use the same framework for defining training content, allowing valid comparisons across athletes and sports. Acknowledging that the very best coaches are often ahead of sport science in employing the fundamental features of training, the aim of this study was to explore successful Norwegian endurance coaches' views on training practices required for winning international medals in endurance sports.

METHODS: Twelve male Norwegian coaches with a track record of coaching endurance world-class athletes (total of >320 Olympic, World and European Championship medals; mainly Norwegian athletes) in cross-country skiing, biathlon, speed skating, rowing, road cycling, swimming, long-distance running and triathlon participated. Initially, we performed training diary analyses of their best-performing athletes followed by interviews with each of the coaches about their views on training practices required to win future international medals in their sports.

RESULTS: Our preliminary analyses shows that all coaches employ a high-volume approach, ranging from 600 annual training hours in running up to 1400 hours in triathlon. In all cases, around 90% the training time is aerobic endurance, in which 80-90% of this contains low-intensity endurance training interspersed by 2-3 days (i.e. 2-5 key sessions) weekly at

higher intensities. All coaches utilize a tradidional periodization model where key sessions becomes gradually more competition-specific towards the competition period. The sport-specific differences in training content are mainly caused by variations in mechanical and muscular loading. Detailed training data in terms of volume, intensity distributions and use of exercise modes periodized throughout the year will be presented and discussed during the presentation.

CONCLUSION: This study illustrates how successful endurance coaches describe "state-of-the-art" endurance training, including quantitative and qualitative insights in common features and sport-specific variations in best practice training organization and characteristics in endurance sports.

SYSTEMATIC REVIEW OF 92 MARATHON TRAINING PLANS

APPELHANS, D., KNOPP, M., SCHÖNFELDER, M., WACKERHAGE, H.

TECHNICAL UNIVERSITY OF MUNICH

INTRODUCTION: A typical training plan is a mix of many interventions, such as runs of different lengths and intensities. It is virtually impossible to measure the effectiveness of such a complex, months-long intervention in high quality intervention trials such as a randomised control trial [1]. To start addressing this evidence problem, Haugen et al. have summarised training plans of elite athletes that have achieved world-class performance despite or because of the training plan [2]. They termed this approach results-based practice. The aim of this study was to use a novel systematic review strategy to quantitatively analyse subjective sub-elite marathon training plans in order to determine a typical marathon training recommendation and report recommended training strategies.

METHODS: We obtained training plans from non-scientific sources using the search term "marathon training". We found 92 training plans and transcribed them into a uniform format with the goal to split each session into a kilometre distance in each of the five intensity zones [3]. To do this, two researchers independently agreed upon the classification for each session. Subsequently, each training plan was grouped based on the total mileage in the peak week, defined as highest volume week, into low (< 65 km/week), middle (65-90 km/week), and high (> 90 km/week) training volume.

RESULTS: Low mileage training plans had an average weekly volume of 43.5 ± 15.5 km that was split into 9.9 ± 3.6% in zone 1, 68.6 ± 5.7% in zone 2, 16.5 ± 5.9% in zone 3, 2.8 ± 1.0% in zone 4, and 2.2 ± 0.5% in zone 5. Low mileage training plans recommend the shortest weekly long runs of 20.5 ± 8.3 km ($p < .001$). Next, the middle mileage training plans recommended an average weekly volume of 58.1 ± 19.4 km with 15.4 ± 1.8% in zone 1, 61.3 ± 4.5% in zone 2, 17.6 ± 5.1% in zone 3, 2.3 ± 0.6% in zone 4, and 3.3 ± 0.5% in zone 5, and recommended an average weekly long run session of 23.0 ± 8.3 km. Lastly, high mileage training plans recommended an average weekly volume of 104.9 ± 39.2 km that was split into 15.0 ± 4.5% in zone 1, 68.1 ± 4.8% in zone 2, 8.7 ± 3.7% in zone 3, 5.2 ± 2.9% in zone 4, and 3.0 ± 1.2% in zone 5, and had the longest weekly long runs of 26.9 ± 7.9 km ($p < .001$). Especially, the high mileage training plans recommended a polarized training intensity distribution with around 85% in zone 1+2 and 8% in zone 4+5.

CONCLUSION: There is a lack of experimental high-quality evidence for the effectiveness of complex training plans over several months. By performing a systematic, quantitative analysis of 92 marathon training plans, we determined typical recommendations for varying performances. Whilst this approach has obvious limitations such as no measurement of the resulting marathon performance, it is arguably a useful strategy to address the evidence problem in training practice.

THE RELATIONSHIP BETWEEN THE MODERATE-HEAVY BOUNDARY AND CRITICAL SPEED IN RUNNING

HUNTER, B.1, MEYLER, S.2, MAUNDER, E.3, MUNIZ-PUMARES, D.2

1. LONDON METROPOLITAN UNIVERSITY, 2. UNIVERSITY OF HERTFORDSHIRE, 3. AUCKLAND UNIVERSITY OF TECHNOLOGY

INTRODUCTION: Training characteristics including duration, frequency, and intensity can be manipulated to maximise endurance performance (1). There is a growing interest in the role of training intensity distribution (TID) to augment training adaptations (2). Typically, TID is determined from the percentage of time spent exercising in the moderate (below gas exchange (GET) or lactate threshold (LT)), heavy (above GET/LT but below critical speed (CS)), and severe (above CS) intensity domains. Estimates of the heavy-severe intensity boundary can be determined from habitual training (3). However, the determination of GET or LT (T1) necessitates testing which can be costly and time-consuming. Thus, determination of the percentage at which T1 occurs relative to CS may permit easier prescription or remote monitoring of TID. A further aim was to examine whether this differs between fitness levels.

METHODS: A literature search was conducted on two databases (PubMed and Scopus). After analysing 1,198 resultant articles, studies were included if they met the following inclusion criteria: 1) CS was reported, 2) either GET or LT was reported, and 3) participants were 18+. Twenty-two studies were included in the final analysis with 458 participants. Studies were grouped into three groups based on the mean CS: low, medium, and high. A sample size-weighted mean and SD, and confidence intervals were calculated for the percentage of CS at which T1 occurred in each group. Hedge's g was used to calculate effect sizes between the three groups of mean CS.

RESULTS: The CS across the included studies was 13.56±2.55 km·h−1 (95% CI [13.33,13.79]). The CS of the low, medium, and high CS subgroups was 11.09±1.85 km·h−1 (95% CI [10.78,11.40]), 13.40±1.45 km·h−1 (95% CI [13.18,13.61]), and 15.93 km·h−1 (95% CI [15.65,16.21]), respectively. Across all studies, T1 occurred at 82.6±14.0% CS (95% CI [81.4,83.9]). In the low,

medium, and high CS groups, T1 occurred at 80.1±18.2% CS (95% CI [77.9,84.0]), 83.2 ± 11.9% CS (95% [81.4,85.0]), and 83.5±11.4% CS (95% CI [81.7,85.3]), respectively. Hedge's g revealed a tendency for the percentage of T1 to be greater in the medium (g=.205); and high (g=.229) CS group compared to the low CS group. A trivial effect size was noted between the medium and high groups (g=.025).

CONCLUSION: It was demonstrated that T1 occurs at approximately 83% of CS. However, this may differ due to different fitness levels. The 95% CI in each tertile demonstrates uncertainty in where T1 occurs relative to CS. This may be due to inconsistent approaches used to determine T1 and CS. Still, the findings provide a basis on which remote analysis and prescription of TID can be performed. Further work could explore the potential to model the relationship between T1 and CS based on fitness levels, sex, and anthropometry.

VALIDATION OF END OF SESSION DISTANCE LIMIT BALANCE FOR DIFFERENTIATING EXHAUSTIVE AND NON-EXHAUSTIVE INTERMITTENT TRAINING SESSIONS IN RUNNERS

BELLENGER, C.

UNIVERSITY OF SOUTH AUSTRALIA

INTRODUCTION: The accurate modelling of intermittent running sessions by the Distance limit (D') balance would aid in the prescription of such sessions, and enhanced understanding of their demands. During cycling, Work limit (W') balance can be quantified using the model described by Skiba et al. [1] which allows W' depletion to be tracked while work rate is above critical power (CP), and determines exponential recovery of W' while work rate is below CP. While the Skiba model can validly quantify W' balance in recreational athletes during cycling [1], the model has not been validated in intermittent running sessions, which is this project's aim.

METHODS: The study is a retrospective analysis of a typical period of racing and training completed between December 2021 and March 2022 by national level endurance runners (n=6). Critical speed (m/s) and D' (m) were calculated from the linear relationship between distance (Y axis) and time (X axis) over 1500, 3000 and 5000m race distances. Intermittent training sessions (n=30) were classified as exhaustive (n=15) vs non-exhaustive (n=15) by the athletes' coach. Timestamped GPS data (i.e. speed) from the training files were exported from TrainingPeaks to CSV files. Within session D' balance was calculated at each timepoint using the D' depletion and recovery models proposed by Skiba et al. [1], allowing an end of session D' balance to be found. End of session D' balance for exhaustive vs non-exhaustive intermittent sessions was compared using independent samples t-test.

RESULTS: There was a large difference (effect size±95% CI=1.20±0.72; p=0.003) between end of session D' balance in exhaustive (mean±95% CI=173±19m; 63±6%) vs non-exhaustive (212±14m; 74±6%) sessions, indicating that end of session D' balance calculated using the Skiba model did differentiate between exhaustive vs non-exhaustive intermittent sessions. However, the 95% CI of end of session D' balance in exhaustive intermittent sessions did not include "0", indicating that end of session D' balance calculated using the Skiba model did not accurately quantify these sessions as exhaustive.

CONCLUSION: Since the D'/W' depletion model is accepted [2], the inaccurate quantification of end of session D' balance during exhaustive intermittent running sessions may be related to the exponential recovery of D' that is reliant on an accurately quantified recovery time constant. In cycling, this recovery time constant is scaled in relation to the absolute watts below CP that the individual is cycling at during recovery, and validated in recreational athletes [1]. Since one watt in cycling is not equal to one m/s in running, and the runners in the current study were highly trained [3], the Skiba recovery model may not be valid for accurate calculation of end of session D' balance during the intermittent running sessions performed by athletes in the present study.

OP-PN03 Physiology and Ageing

A POTENTIAL MECHANISM FOR THE PROTECTIVE EFFECTS OF EXERCISE ON NEUROMUSCULAR FUNCTION WITH AGEING

SOENDENBROE, C.1,2, SCHJERLING, P.1,2, KJAER, M.1,2, HANNIBAL, J.3, JACQUIER, A.4, SCHAEFFER, L.4, MACKEY, A.L.1,2

1> INSTITUTE OF SPORTS MEDICINE COPENHAGEN, BISPEBJERG HOSPITAL . 2> CENTRE FOR HEALTHY AGING, UCPH. 3> DEPARTMENT OF CLINICAL BIOCHEMISTRY, BBH. 4> INSTITUTE NEUROMYOGENE, UNIVERSITÉ LYON

INTRODUCTION: The number of limb motoneurons declines with age (1), leading to an irreversible loss of muscle fibres and ultimately a loss of muscle function. Exercise has neuroprotective effects that facilitate reinnervation of denervated

muscle fibres (2) and potentially also limit motoneuron decay. While there is limited understanding of what drives these neuroprotective effects, muscle-derived factors are likely contenders. The aim of this study was to investigate the neuroprotective properties of muscle cells derived from lifelong exercisers, compared with inactive counterparts.

METHODS: Primary muscle stem cells (MuSC) and fibroblasts (FB) were isolated from biopsy tissue collected from the vastus lateralis muscle of 7 elderly lifelong exercising males (LLEX, age: mean 72 ± SD 3 y, BMI: 25±3 kg/m^2), 6 elderly sedentary males (SED, age: 73±4 y, BMI: 27±3 kg/m^2) and 8 young sedentary males (Young, age: 25±5 y, BMI: 25±3 kg/m^2) (3). Isokinetic concentric leg extensions were performed to assess maximal voluntary contraction (MVC) and muscle performance index during repeated contractions (MPI, % of MVC). Motoneurons from rat embryos were cultured with MuSCs or FBs from each of the 3 groups for 24 hours. Motoneuron survival and neurite growth were analysed by immunofluorescence and RT-qPCR. In vivo data were compared by t-test, and cell culture data by 2-way ANOVA (group x cell).

RESULTS: Compared to SED, LLEX had 15% higher MPI ($p<0.05$) but similar MVC ($p<0.132$), while Young, compared to old groups combined, had 34% higher MVC ($p<0.01$) but similar MPI ($p=0.43$). Motoneurons incubated with muscle cells from LLEX, compared to SED, were characterised by a 63% higher survival ($p<0.001$), and a 55% higher number of neurites per area ($p<0.05$). There were no differences between young and old in vitro. mRNA levels of three "neurite growth" genes revealed cell type specific responses, with two out of three favouring FBs (Fth1, Ppp1r1a) over MuSCs (Rack1).

CONCLUSION: Exercise confers protective effects on neuromuscular health, but how these effects are mediated is largely unresolved. Our data provide a potential explanation, clearly showing that, when compared to inactive older individuals, muscle cells from lifelong exercisers exert a strong stimulatory effect on motoneurons, both in terms of survival and growth. Preservation of motoneurons through exercise could protect against the loss of muscle fibres and associated decline in physical function in old age. In relation to exercise recommendations therefore, it is possible that, while it is never too late to take up regular physical activity, optimal preservation of muscle function can only be achieved by maintaining a physically activity lifestyle throughout life.

LOWER LIMB HYPERTHERMIA SIMILARLY AUGMENTS FUNCTIONAL HYPERAEMIA DURING KNEE-EXTENSOR EXERCISE IN TRAINED ELDERLY AND YOUNG HUMANS

KOCH ESTEVES, N., GONZÁLEZ-ALONSO, J.

BRUNEL UNIVERSITY LONDON

INTRODUCTION: Exercise and heat therapies are commonly recommended to improve vascular function and health in young and elderly people (1, 2). Ageing is associated with reduced limb tissue and systemic perfusion during passive and exertional whole-body hyperthermia (3) and large-muscle groups exercise (4); however, evidence in isolated limb hyperthermia, small-muscle group exercise and its combination is conflicting (5). Here, we tested the hypothesis that the combination of single-leg hyperthermia and knee-extensor exercise would have an additive effect on limb haemodynamics, albeit lower in the elderly group.

METHODS: Nine trained, healthy elderly (69±5 years) and ten young (26±7 years) adults underwent 90 min of single-leg heating followed by 10 min of low-intensity single-leg knee-extensor exercise at 6 W and 12 W work rate (5 min each), with both the heated and control legs. Temperature and tissue oxygenation profiles, and leg haemodynamics at the femoral and popliteal arteries were measured.

RESULTS: In both groups, passive leg heating increased whole-leg skin temperature, blood flow and tissue oxygenation by 9.3±1.6 ºC, 0.7±0.2 L/min (>3-fold), and 18±6 % units ($p<0.0001$), respectively. Larger increases in leg blood flow were seen in the heated leg in comparison to the control leg during exercise (3.1±0.6 vs 2.3±0.4 L/min, $p<0.0001$) as leg blood flow was tightly coupled to leg temperature ($R2=0.77$, $k=0.27$ [0.05, 0.70]). Shear rate increased 3-fold during leg heating, 8-fold during control exercise, and 10-fold during heated exercise ($p<0.0001$). There were no differences in limb haemodynamics between cohorts, other than the elderly group exhibiting a 16±6 % larger arterial diameter, a 51±6 % lower blood velocity, and a 73±7 % lower shear rate following heating ($p<0.0001$).

CONCLUSION: Local hyperthermia increased leg blood flow over 3-fold and had an additive effect during knee-extensor exercise with no differences in leg perfusion between the healthy, exercise-trained elderly and the young groups. Hence, against our hypothesis, age per se does not compromise local hyperthermia-induced or small-muscle group functional hyperaemia despite evident aged-related structural and functional differences in the leg conduit arteries. The novel finding that leg hyperthermia induced a 2–3-fold higher shear rate—an important stimulus for vascular adaptation (2)—during rest and exercise may have important implications for elderly, sedentary populations who are not able to participate in sustained exercise. The combination of lower limb heating with low-intensity exercise may be a suitable intervention to enhance the stimulus for vascular adaptation without inducing systemic thermal discomfort and physiological strain.

ENDURANCE TRAINING COUNTERACTS AGE-RELATED FUNCTIONAL AND STRUCTURAL ALTERATIONS OF NEUROMUSCULAR JUNCTION IN MICE

YAMAGUCHI, T.1, KOZAKI, K.2, NAKAZATO, K.2, SASAKI, K.1

1. THE UNIVERSITY OF TOKYO, 2. NIPPON SPORT SCIENCE UNIVERSITY

INTRODUCTION: The deterioration of neuromuscular junction (NMJ) is considered one of the factors of muscle weakness in old age. The structural alteration of NMJ can not only impair the signal transmission from motor neurons to muscle fibers, but also lead to the alterations in muscle fiber type through repeated cycles of denervation and reinnervation. Several studies have found that endurance training influences the structure of NMJ in aged mice (1), but its effects on the functions of NMJ remain unclear. The purpose of this study was to clarify the effect of endurance training on the function and structure of NMJ in aged mice.

METHODS: Young (3 months old) and aged (22 months old) male C57BL/6J mice were divided into three groups: Y (young, n = 10), AC (aged control, n = 8) and AT (aged trained, n = 8). AT was subjected to low intensity treadmill running (5–15 m/min, 15–60 min) five times a week for eight weeks, while Y and AC remained untreated. After the intervention period, we examined voluntary grip strength, neuromuscular transmission index (the ratio of evoked plantar flexion torques between supramaximal nerve and muscle stimulations), muscle fiber composition and the structure of NMJ (axon width, nerve terminal area, acetylcholine receptors area, pre- to post-synaptic overlap) in the plantaris and soleus muscles. A one-way ANOVA followed by Tukey's post hoc test and a two-way ANOVA followed by Holm-Bonferroni post hoc test were performed to detect differences. The difference was considered statistically significant at $p < 0.05$.

RESULTS: AC had a significantly lower grip strength than Y and AT. The wet weight of the plantaris and the soleus muscles was significantly smaller in AC than in Y, but was similar between AC and AT. The neuromuscular transmission index of AC was significantly lower than that of Y and AT. The size of the nerve terminal area and the synaptic overlap in the plantaris and fast-twitch fibers in the soleus were significantly lower in AC than in Y. The overlap was significantly correlated to the transmission index. AC showed a significantly higher proportion of type I fibers and a significantly lower proportion of type IIb/IIx fibers in the soleus than Y. The proportions of the denervated NMJ in the plantaris and the soleus were significantly higher in AC than in Y and AT. In AC, the proportion of the denervated NMJ in the soleus was significantly higher in fast-twitch fibers than in slow-twitch fibers.

CONCLUSION: These results suggest that the age-related decline in the pre- to post-synaptic overlap of NMJ is associated with the impairment of neuromuscular transmission. The age-related denervation is pronounced in fast-twitch fibers, resulting in the reduced proportion of fast-twitch fibers. Endurance training can counteract these alterations, thus contributing to the maintenance of voluntary muscle strength.

AGE-DEPENDENT CEREBRAL BLOOD FLOW RESPONSES TO ACUTE CONCURRENT PHYSICAL AND COGNITIVE ACTIVITY

MCCARTHY, V., RATTRAY, B., NORTHEY, J.

UNIVERSITY OF CANBERRA

INTRODUCTION: Concurrent physical and cognitive training may be a viable intervention to support cognitive function throughout the lifecycle, by combining the benefits of each into an efficient protocol. Transient increases in cerebral blood velocity have been proposed as a potential mechanism responsible for the observed cognitive benefit. However, little is known about the acute cerebral haemodynamic response to concurrent training, and how this may be influenced by age. This study compared the cerebral blood velocity response to physical only and concurrent training and assessed the potential age-related differences in this response.

METHODS: Fourteen younger (25±2 years, 7 female) and fourteen older (64±3 years, 8 female) adults completed two exercise protocols in a randomised order. Participants cycled for 30-minutes at 60% of their maximal aerobic power output, with the addition of an incongruent Stroop Task (Exercise-Stroop) and without (Exercise-Only). Transcranial doppler ultrasound was used to simultaneously record cerebral blood velocity within the right middle (MCA) and left anterior (ACA) cerebral arteries, with average values recorded at 7-minute intervals during each protocol. A general linear mixed model was used to determine the effects of time, condition (Exercise-Stroop vs. Exercise-Only), and age (younger vs. older adults) on the recorded velocities within each vessel.

RESULTS: No three-way interaction effects (time*condition*age) were observed for the MCA ($p=0.95$) or ACA ($p=0.76$), and no significant two-way interactions with condition were identified for either vessel. A time*age interaction was noted for both MCA ($b= 5.4$ to 7.5 cm/s, $p<0.05$) and ACA ($b= 4.9$ to 7.9 cm/s, $p<0.05$) velocities, with the older group steadily declining towards baseline values across the duration of each protocol.

CONCLUSION: Regardless of age, concurrent engagement in physical and cognitive activity did not modify cerebral blood velocities beyond those observed during exercise. However, the capacity to sustain the elevations in velocity appears to be influenced by age, potentially the result of age-related changes in cerebrovascular function. Future research should

assess the influence of these age-related cerebrovascular changes, and the effect that different cognitive tasks may have on the observed cerebral haemodynamic response to concurrent training.

OP-AP02 Training and Testing: Team sports

SUBMAXIMAL FITNESS TEST IN TEAM SPORTS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF EXERCISE HEART RATE MEASUREMENT PROPERTIES

SHUSHAN, T., LOVELL, R., BUCHHEIT, M., SCOTT, T.J., BARRET, S., NORRIS, D., MCLAREN, S.J.

WESTERN SYDNEY UNIVERSITY

INTRODUCTION: Submaximal Fitness Tests (SMFT) are a pragmatic approach for evaluating athlete's physiological state, due to their time-efficient nature, low physiological burden and relative ease of administration in team-sports settings. Whilst a variety of outcome measures can be collected during SMFT, exercise heart rate (HRex) is the most popular. Understanding the measurement properties of HRex can support the interpretation of data and assist in decision-making regarding athlete's current physiological state and training effects. The aims of our systematic review and meta-analysis were to: 1) establish meta-analytic estimates of SMFT HRex reliability and convergent validity; and 2) examine the moderating influence of athlete and protocol characteristics on the magnitude of these measurement properties.

METHODS: We conducted a systematic literature search with MEDLINE, Scopus and Web of Science databases for studies published up until January 2022 since records began. Studies were considered for inclusion when included team-sports athletes and the reliability and/or convergent validity of SMFT HRex was investigated. Reliability statistics included the group mean difference (MD), typical error of measurement (TE) and intraclass correlation coefficient (ICC) derived from test-retest(s) designs. Pearson's correlation coefficient (r) describing the relationship between SMFT HRex and a criterion measure of endurance performance was used as the statistic for convergent validity. Mixed-effects, multilevel hierarchical models, combined with robust variance estimate tests were performed to obtain pooled measurement property estimates, effect heterogeneity, and meta- regression of modifying effects.

RESULTS: The electronic search yielded 21 reliability (29 samples) and 20 convergent validity (29 samples) studies that met the inclusion criteria. Reliability meta-analysis indicated good absolute (MD = 0.5 [95% CI: 0.1 to 0.9] and TE = 1.6 [1.4 to 1.9] % points), and high relative (ICC = 0.88 [0.84 to 0.91]) reliability. Convergent validity meta-analysis indicated an inverse, large relationship (r = –0.58 [–0.62 to –0.54]) between SMFT HRex and endurance tests performance. Meta-regression analyses suggested no meaningful influence of SMFT protocol or athlete characteristics on reliability or convergent validity estimates.

CONCLUSION: Submaximal Fitness Test HRex is a reliable and valid proxy indicator of endurance performance in team-sport athletes. Athlete and SMFT protocol characteristics do not appear to have a meaningful effect on these measurement properties. Practitioners may implement SMFT HRex for monitoring athlete's physiological state by using our applied implications to guide the interpretation of data in practice. Future research should examine the utility of SMFT HRex to track within-athlete changes in aerobic capacity, as well as any further possible effects of SMFT protocols design elements or HRex analytical methods on measurement properties.

MAXIMIZING PHYSICAL PERFORMANCE IN FEMALE HANDBALL PLAYERS DURING THE COMPETITIVE SEASON: THE IMPACT OF HIGH-LOAD STRENGTH TRAINING VERSUS POWER-PLYOMETRIC TRAINING

VÅRVIK, F.T.1, BJØRNSEN, T.1, TORSTVEIT, M.K.1, PEDERSEN, S.M.1, GRANLI, A.1, AUNE, S.S.1, MARTINOVIC, E.1, RAASTAD, T.1,2

1. UNIVERSITY OF AGDER, 2. NORWEGIAN SCHOOL OF SPORT SCIENCES

INTRODUCTION: Handball players practice various types of resistance training to enhance physical performance. Whether it is beneficial to prioritize high-load or high-velocity resistance training for preserving strength and power capacities throughout the in-season period remains to be determined. As such, the aim of this study was to compare the effects of in-season power and plyometric training versus high-load strength training on body composition and strength- and power performance.

METHODS: Thirty-one female handball players from two senior sub-elite teams were randomized into high-load strength training (high-load; n=16, 20±3yrs, 170±6cm, 70±14kg) or power and plyometric training (power-plyo; n=15, 20±3yrs, 170±6cm, 66±7kg). Biweekly training sessions were conducted for 12 weeks and supervised once a week. The high-load group performed 2-6 sets per muscle group at 80-85% 1RM, while power-plyo completed 75-90 bodyweight jumps in addition to 2-4 sets of 3-6 power exercises at ≤50% 1RM. Before and after the training period, 1RM in squat and bench press, theoretical maximal force (Fmax) and -power (Pmax) from pneumatic leg press, and bench press power by a linear encoder were assessed. Countermovement jump (CMJ) height was measured on a force plate, and vertical reach with single-leg jump-and-reach. Sprint (10-, 20-, and 30m) and change of direction (CoD) times (4x180° turns) were measured with timing gates, and body composition was assessed using Dual-X-Ray-Absorptiometry. All data were analyzed with t-tests and are reported as mean change with 95% confidence intervals or standard deviations.

RESULTS: Training attendance was 90±8% in the high-load group and 90±9% in the power-plyo group. Further, 1RM increased more in high-load compared to power-plyo, squat by 8.6% (1.4, 15.7, p=0.02) and bench press by 6.6% (0.7, 12.6, p=0.03). No between-group differences were observed in other parameters (p=0.17-0.95). Compared to baseline, both groups improved (all p<0.05); Fmax (high-load: 8.5±9.8%, power-plyo: 4.9±8.2%), Pmax (high-load: 10.5±7.6%, power-plyo: 8.5±7.3%), bench press power (high-load: 8.1±9.8%, power-plyo: 5.5±10.2 (tendency p=0.06), CMJ (high-load: 6.6±6.9%, power-plyo: 7.2±5.4%) and jump-and-reach (high-load: 5.6±8.0%, power-plyo: 6.1±9.5%). Sprint was unchanged, but high-load improved CoD (2.0±2.5% vs. 1.0±2.6%). No changes were observed in body mass or fat mass, but both groups increased fat-free mass (FFM, high-load: 2.0±2.0%, power-plyo: 1.7±2.3%) and legs FFM (high-load: 2.5±2.9%, power-plyo: 2.9±2.3%).

CONCLUSION: Our findings suggest that if maximal strength is prioritized, handball players should choose high-loads over power-plyo training during the in-season; otherwise, they may use either approach to maintain or increase FFM, power, jump, and sprint performance. However, more research is needed to elucidate specific neuromuscular adaptations of high-loads versus high-velocity training to better understand and prescribe in-season training programs for handball players.

AN EVALUATION OF THE FACTORS PREDICTING TOTAL ATHLETIC ABILITY VIA ENERGETIC MODELLING OF A SINGLE-VISIT, OVERGROUND ASSESSMENT OF THE SPEED- AND POWER-DURATION RELATIONSHIP IN TEAM SPORTS PLAYERS

VASSALLO, C., GRAY, A., KILDUFF, L.P., JENKINS, D., WALDRON, M.

SWANSEA UNIVERSITY

INTRODUCTION: The 3-minute all-out test (3MT) provides a single-visit, field-based method to characterise parameters of the overground speed-duration relationship. Data from this test can be used to determine whole-body power output using a novel energetics modelling approach. When all speed and mechanical outputs captured during the single-visit assessment of the overground speed- and power-duration relationship are considered, it is possible that they could explain variance in athletes' overall physical ability. This could help to determine team sport athletes' total score of athleticism (TSA), which relies on a battery of separate physical performance tests. This can be logistically impractical and poorly adopted by coaches. However, it is unclear whether data extracted from the 3MT can explain variance in TSA and which variables have the greatest relative contributions. This study aimed to evaluate the variance explained in a composite battery of physical performance tests to overground running mechanical parameters derived from a 3MT.

METHODS: Following ethical approval, 94 competitive team sport players consented to take part in three separate testing visits. Across days, this included assessment of: countermovement jumping (CMJ) on a force plate; 0-to-30-m overground sprinting, measured using electronic timing gates and a Yo-Yo intermittent recovery level 1 (Yo-Yo IR1) test. The TSA was calculated using a summated z-score from: jump height, CMJ peak power, Yo-Yo IR1 score, 10-m and 30-m speed. Additionally, an overground 3MT was conducted using a 10-Hz global positioning system (GPS), from which critical speed and Distance-prime (D') were determined. Energetic modelling was used to determine over-ground mechanical work, from which critical power (CP) and Work-prime (W') were calculated. Partial least squares regression (PLSR) was used to explain variance in the TSA using 8 variables derived from the 3MT. The number of components explaining the greatest variance (R2) in TSA were selected in the final model. The contribution of each variable to the overall model was calculated via the jack-knife function.

RESULTS: The final model comprised one component, which explained 47.2% of the variance in TSA. The strongest variables contributing to the overall model were: CP (beta=4.22, P<0.001) W' (beta=4.49, P<0.001), maximal mechanical power (beta=5.06, P< 0.001), total mechanical work per metre-squared of body surface area (beta=6.14, P <0.001), maximal force production (beta=3.23, P=0.002) and peak speed (beta=4.75, P<0.001). Critical speed (beta=2.02, P=0.01) and D' (beta=1.81, P=0.04) were the weakest contributors.

CONCLUSION: Mechanical parameters derived from the 3MT provided the strongest contributions in the model, which overall explained 47.2% of variance in TSA. These preliminary data demonstrate the potential utility of overground power-duration parameters for athlete profiling but question its capacity, in its current form, to capture all aspects of athletic ability.

THE RELATIONSHIP BETWEEN SPECIFIC GAME-BASED AND GENERAL PERFORMANCE IN YOUNG ADULT ELITE MALE TEAM HANDBALL PLAYERS

WAGNER, H., HINZ, M.

UNIVERSITY OF SALZBURG

INTRODUCTION: In young adult elite team handball players, physical performance is an essential factor for becoming a top-elite player and should be measured adequately. However, in elite team handball academies, general, unspecific tests are often used to determine this physical performance. It is unknown if these unspecific physical performance tests have an influence on the specific team handball performance, although this knowledge is essential for the selection process during adolescence or for young adults before transitioning to professional elite team handball. Additionally, reducing the overall testing time and the test equipment is also important for an economical testing. Consequently, the aim of the study was (1) to analyze the relationship between specific game-based and general physical performance in young elite male team handball players, and (2) to reduce the number of tests for a more practical implementation of physical performance diagnostics in team handball.

METHODS: Twenty young adult elite male team handball field players (18.6 ± 2.1 years) performed the team handball game-based performance test (GBPT) and general tests including a 20 m sprinting test, a repeated sprint ability test (RSA), a modified T-test, countermovement (CMJ), squat (SJ) and drop jump test (DJ), a standing long jump test, a single-leg lateral three jumps test, a standing throw test, and the determination of the one repetition maximum (1RM) in the bench press, bench pull, front squat, and deadlift. The relationship between general physical performance tests (the GBPT) and anthropometric variables (body height and weight) was determined by calculating Pearson Product-Moment correlation coefficients. Additionally, a principal component factor analysis was conducted to determine a few components that define multiple variables.

RESULTS: Significant correlations (> 0.60 or < -0.60) were mostly found between different sprinting and jumping tests (20 m sprinting test, RSA, modified T-test, defense time in the GBPT, CMJ, SJ and DJ test, standing long jump test, and the single-leg lateral three jumps test) as well as between different strength tests (1RM in the bench press, bench pull, front squat, and deadlift) and body weight. The principal component factor analysis revealed four components (power and speed, strength, jump shot performance, and endurance) including 21 variables of high loads (> 0.60 or < -0.60).

CONCLUSION: To reduce the number of tests and optimize the testing process in elite team handball, we suggest five physical performance tests (20 m sprinting test, GBPT, CMJ test, 1RM in the bench press and front squat) that enable testing several times in one season. However, due to the high financial costs of the GBPT (for equipment and manpower), we would suggest a different testing procedure in youth and non-elite team handball, including six physical performance tests (20 m sprinting test, T-test, CMJ test, 1RM bench press and front squat, as well as the YoYo intermittent recovery test).

CONSTRUCT VALIDITY OF A NEW DECREASING RECOVERY INTERMITTENT RUNNING TEST IN SOCCER

BENEDETTI, L.1,3, NIGRO, F.1, MANARI, D.2, MANARI, G.2, FARACI, G.2, CECI, G.2,3, AIELLO, P.3, PRANDELLI, N.3, NANNI, G.3,4, SISCA, G.3,4, BINI, L.3,4, ROSSI, G.3,4, ANDREINI, G.3, MARCORA, S.M.1

1. UNIVERSITY OF BOLOGNA, 2. THE OXYGEN UPTAKE PROFESSIONAL TEAM, REGGIO EMILIA, 3. BOLOGNA F.C. 1909, 4. ISOKINETIC MEDICAL GROUP CENTER, BOLOGNA;

INTRODUCTION: In recent years a new protocol of an intermittent running test with decreasing recovery called MAP (MAnari Protocol from the surname of his inventor) has been used to assess professional soccer players. However its validity is yet to be established. The main aim of the study was to explore MAP construct validity by examining the correlation between the peak of oxygen consumption (VO2peak) and other variables measured by MAP and various parameters of match physical performance. A secondary aim was to validate the Mognoni Test (MT) (1).

METHODS: Ten Serie A players were tested with MAP and MT. The selected parameters of match physical performance (raw and normalized by min played) were: metabolic power, very high power, high power distance, high and very high speed running distance, maximum acceleration and maximum deceleration distance, total distance (2). After warm-up, players performed to volitional exhaustion sets of 3 to 7 50m intermittent runs at 18 km/h with recovery between each run decreasing after each set (from 17s in the first set to 2s in the final set). VO2peak, ventilatory parameters like the respiratory compensation point (RCP), lactate, and MAP distances were recorded. 48 hours later players were also tested with MT to estimate the speed at the onset of blood lactate accumulation (OBLA). Parameters of match physical performance were obtained from the average of two video-tracked matches played for at least 45 min within 2 weeks from the date of the MAP and MT.

RESULTS: VO2peak was positively correlated with power variables, high speed distances, distance maximum accelerations and decelerations per min, total distance per min during the match. MAP distance was positively correlated with power variables (metabolic power, high distance power) and match-related distance variables (total distance, total distance per min). Lactate at the end of MAP was positively correlated only with average metabolic power per min. The difference between the MAP distance and distance at RCP, was positively correlated with power variables (metabolic power, very high distance power) high speed distance, distance maximum acceleration and decelerations per min, total distance per min and maximum speed. Speed at OBLA estimated with the MT was negatively correlated with distance run at very high speed and with distance run at very high power, and their respective values per min.

CONCLUSION: This study provides empirical support to the construct validity of both the MAP and the MT as indicators of between-subject differences in match physical performance in professional soccer players. With the exception of distance at OBLA, all MAP variables correlate significantly with various parameters of match physical performance. MAP variables requiring the use of a portable metabolimeter do not show superior construct validity compared to MAP distance.

SHORT-TERM LOW ENERGY AVAILABILITY DOWN-REGULATES CIRCULATING TRIIODOTHYRONINE AND BONE FORMATION MARKERS IN MALES, WHILST SKELETAL MUSCLE PROTEIN SYNTHESIS IS PRESERVED.

TAYLOR, H.L., BURNISTON, J., NISHIMURA, Y., FOO, W.L., STRAUSS, J., COCKS, M., SHEPHERD, S., LANGAN-EVANS, C., MORTON, J.P., ARETA, J.L.

LIVERPOOL JOHN MOORES UNIVERSITY

INTRODUCTION: Low energy availability (LEA) is thought to downregulate the hypothalamic-pituitary-axes and impair bone health and physical capacity in exercising individuals. However, the effect of LEA on skeletal muscle is unclear. This study aimed to assess the effect of five days of LEA on endocrine, metabolic, physiological, and skeletal muscle phenotype responses in males.

METHODS: In a quasi-experimental design, 10 healthy males (25 ± 5 yrs, body mass: 78.8 ± 8.2 kg, VO2peak: 52 ± 8 ml/kg/min) completed three consecutive 5-day periods of 1) free-living, 2) energy balance (EB: energy availability (EA) = 45 kcal/kg Fat Free Mass [FFM]/day), and 3) LEA (EA = 10 kcal/kg FFM/day). EB and LEA diets provided 60% carbohydrate, 20% fat, 20% protein, and participants performed standardised cycling exercise to expend 15 kcal/kg FFM on days 1, 3 and 5 of EB and LEA. Skeletal muscle phenotype shift was determined via proteomics. To determine dynamic proteomic profiling, participants consumed D2O daily and muscle biopsies were collected from the vastus lateralis at the start and end of each period. Body composition and resting metabolic rate (RMR) were also collected at these timepoints. Fasting venous blood was collected throughout and assessed for plasma total triiodothyronine (T3) and markers of bone resorption (ß-CTX) and formation (P1NP). Data were explored via one-way ANOVA and linear mixed models.

RESULTS: Body mass, FFM, and fat mass were stable during EB but reduced by 2.9 ± 0.7 kg ($P < 0.001$), 2.1 ± 0.7 kg ($P < 0.001$), and 0.8 ± 0.6 kg ($P = 0.003$), respectively after LEA. RMR was unchanged following LEA ($P = 0.151$). Compared to baseline concentrations (131 ± 22 ng/dL), T3 was reduced following LEA (108 ± 23 ng/dL; $P = 0.009$). Plasma ß-CTX was higher after four days of LEA (0.90 ± 0.23 µg/L) compared to four days of EB (0.80 ± 0.29 µg/L; $P = 0.020$), whilst P1NP concentrations reduced from 79.3 ± 22.7 µg/L to 67.3 ± 17.8 µg/L ($P < 0.001$) after LEA. Proteomic analysis determined the abundance of 1550 proteins and turnover of 565 proteins. Between EB and LEA, there were no differences in global fractional synthetic rates of the myofibrillar, soluble, and mitochondrial protein fractions. After LEA, the abundance of 131 proteins and turnover of 20 proteins were significantly different ($P < 0.05$) compared to EB. KEGG pathway analysis revealed alterations in protein abundance associated with metabolic pathways, including mitochondrial function, fatty acid, and branched-chain amino acid metabolism.

CONCLUSION: In conclusion, five days of LEA reduced markers typically associated with LEA, including plasma T3 and P1NP concentrations in males. Global protein synthetic rates for myofibrillar, soluble and mitochondrial fractions were preserved following LEA and skeletal muscle phenotype shifted towards fatty-acid metabolism. These data suggest that despite down-regulated endocrine responses to LEA, skeletal muscle protein turnover is preserved with concomitant alterations in skeletal muscle phenotype.

INGESTION OF MYCOPROTEIN, PEA PROTEIN OR THEIR BLEND SUPPORT COMPARABLE POST-EXERCISE MYOFIBRILLAR PROTEIN SYNTHESIS RATES IN RESISTANCE TRAINED INDIVIDUALS.

WEST, S.

UNIVERSITY OF EXETER

INTRODUCTION: Pea protein is commercially advanced, digestible and leucine rich (>5.9% total protein), making it an attractive non-animal derived protein source for supporting post-exercise myofibrillar protein synthesis (MyoPS). However, a low methionine content (<1.6% total protein – WHO criteria) has been suggested to limit its anabolic potential. Mycoprotein has a more balanced amino acid profile which, at least in part, explains its ability to robustly stimulate MyoPS rates. We hypothesised that an inferior post-exercise MyoPS response would be seen following ingestion of pea protein compared with mycoprotein, which would be (partially) rescued by blending the two sources.

METHODS: Thirty-three healthy, young (age; 21±1 y, BMI; 24±1 kg.m-2) and resistance trained volunteers participated in a randomised, double-blind parallel group trial. Participants received primed, continuous infusions of L-[ring-2H5]phenylalanine and completed a bout of whole-body resistance exercise before ingesting 25 g protein from mycoprotein (MYC; 1.7 g leucine, 0.4 g methionine, n=11), pea protein (PEA; 1.9 g leucine, 0.2 g methionine, n=11) or a blend (39% MYC, 61% PEA) of the two (BLEND; 1.7 g leucine, 0.3 g methionine, n=11). Blood and muscle (vastus lateralis) samples were taken pre-, 2 h and 4 h post- exercise/protein ingestion to assess postabsorptive and temporal postprandial postexercise myofibrillar protein fractional synthetic rates (FSRs). Two-way ANOVAs were used to detect differences in plasma amino acid kinetics (group × time) and myofibrillar FSRs (group × time), with Sidak tests applied post-hoc.

RESULTS: Protein ingestion increased plasma essential amino acid and leucine concentrations (time effect; $P<0.0001$), but more rapidly in BLEND and PEA compared with MYC (time x condition interaction; $P<0.0001$). Postprandial plasma methionine availability (4 h iAUC) was greater in MYC (576 µmol·L-1 x 240 min) compared with BLEND (-188 µmol·L-1 x 240 min) and PEA (-567 µmol·L-1 x 240 min). From similar postabsorptive values (MYC, 0.026±0.008%·h-1; PEA, 0.028±0.007%·h-1;

BLEND, 0.026±0.006%·h-1), resistance exercise and protein ingestion increased myofibrillar FSRs (time effect; P<0.0001) over a 2 h (MYC, 0.077±0.015%·h-1; PEA, 0.089±0.014%·h-1; BLEND, 0.091±0.013%·h-1) and 4 h (MYC, 0.076±0.004%·h-1; PEA, 0.087±0.01%·h-1; BLEND, 0.085±0.01%·h-1) period, with no differences between groups (all; P>0.05).

CONCLUSION: Ingestion of isonitrogenous boluses of mycoprotein, pea protein and their blend results in equivalent rates of MyoPS following whole-body resistance exercise. These data suggest that all three non-animal derived protein sources are effective in supporting post-exercise muscle reconditioning.

NUTRITIONAL AND PHYSIOLOGICAL DETERMINANTS OF PEAK FAT OXIDATION IN MODERATELY TRAINED MEN

TARRY, E.K.1,4, PETERSEN, E.A.1, VESTERGAARD, S.G.1, OLSEN, M.C.1, HANSEN, M.1, DELA, F.1,2, PILEGAARD, H.3, SHAW, C.S.4, HELGE, J.W.1

1 UNIVERSITY OF COPENHAGEN, DENMARK; 2 BISPEBJERG UNIVERSITY HOSPITAL, DENMARK; 3 UNIVERSITY OF COPENHAGEN, DENMARK; 4 DEAKIN UNIVERSITY, VICTORIA, AUSTRALIA

INTRODUCTION: Peak fat oxidation (PFO) is strongly linked to metabolism-regulating proteins (1,2),but the extent to which these can be altered using a short-term dietary intervention remains unexamined. Furthermore, the impact of endogenous and exogenous store alteration on PFO has not been fully elucidated. Assessment of muscle characteristics may prove to further explain the variability in PFO largely unaccounted for (3). This study assessed the determinants of PFO using a short-term fat-rich or carbohydrate-rich diet, hypothesising that a fat-rich diet would lead to alterations in substrate availability, and thus elevations in PFO.

METHODS: Moderately trained men [n = 40, VO2peak 56.2 ± 5.1 ml/kg/min, BMI 24.1 ± 1.9 (mean ± SD)] were allocated to either a 3-day isocaloric high-fat (HIFAT: 65% fat, 20% carbohydrate and 15% protein) (n = 20) or high-carbohydrate diet (HICHO: 70% carbohydrate, 15% fat and 15% protein) (n = 20). Participants completed an incremental exercise test to determine PFO and maximal oxygen uptake. Fasting blood samples and a muscle biopsy from the vastus lateralis were collected before and after the diet intervention. Two-way RANOVA were used to assess differences between diet groups over time.

RESULTS: At baseline, simple bivariate analyses revealed VO2 peak (r2 = 0.12, p = 0.03) and FFA (r2 = 0.10 p = 0.0484) were positively associated with PFO. No significant association was found between PFO at baseline and resting muscle glycogen or IMTG. The HIFAT group displayed elevated PFO (0.59 ± 0.18 vs 0.27 ± 0.10 g/min, p = 0.02) compared to HICHO. Muscle glycogen was significantly increased following the carbohydrate-rich diet and reduced by the fat-rich diet, respectively (delta 91.09 ± 142.3 vs -81.66 ± 89.30 nmol/mg dry weight, p < 0.0001). IMTG stores remained unchanged after dietary intervention. Expression of mRNA for key regulatory proteins GLUT4, ANT1, CPT-1 and ß-HAD were not significantly altered by diet, however UCP3 mRNA expression was significantly elevated after HIFAT by 1.7 fold (p = 0.046). Plasma triglyceride and ketone levels were significantly increased following HIFAT (p < 0.05).

CONCLUSION: PFO was significantly elevated after HIFAT and reduced following HICHO. Nutritional interventions of only 3 days provide sufficient duration to elicit metabolic changes facilitating fat oxidation during exercise.

THE EFFECT OF COMBINED JUMP TRAINING AND COLLAGEN SUPPLEMENTATION ON BONE MINERAL DENSITY IN MALE AND FEMALE ELITE CYCLISTS

HILKENS, L.1,3, VAN SCHIJNDEL, N.1, WEIJER, C.1,3, DECROIX, L.2, BONS, J.3, VAN LOON, L.3, VAN DIJK, J.W.1

1 HAN UNIVERSITY OF APPLIED SCIENCES 2 TEAM JUMBO-VISMA 3 MAASTRICHT UNIVERSITY MEDICAL CENTRE+

INTRODUCTION: Accumulating evidence indicates that most elite cyclists have low bone mineral density (BMD). Jumping exercise has been shown to improve BMD, although this has never been investigated in elite-level road-race cyclists. Collagen supplementation may augment the effect of jumping exercise on BMD, as collagen is a key component of bone tissue. The present study aimed to evaluate the effect of combined jump training and collagen supplementation on BMD in elite road-race cyclists.

METHODS: In this open-label, randomized controlled study with two parallel groups, 36 young male (n=8) and female (n=28) elite cyclists (21±3 y, BMI 21±1 kg/m2) were allocated to either an intervention (INT: n=18) or a no treatment control (CON: n=18) group. The 18-wk intervention period, conducted during the off-season, consisted of 5-min jumping exercise bouts performed five times per week, with each exercise bout preceded by the ingestion of 15 g hydrolyzed collagen. Body composition, trabecular bone score (TBS), and BMD of the total hip, femoral neck, lumbar spine and whole body were assessed before and after the intervention period by dual-energy x-ray absorptiometry, along with serum bone turnover markers P1NP and CTX-I. The effect of the intervention on the dependent variables was assessed by using mixed model ANOVA, with time (pre- and post-intervention) as within-subject factor and treatment (CON vs INT) as between-subject factor.

RESULTS: Compliance with the intervention was 3.5±0.9 sessions with collagen supplements per week (77% of planned sessions completed). Lean body mass increased to a similar extent (~2.6%; time-effect: P<0.001) in CON (from 46.3±7.8 to 47.5±7.5 kg) and INT (from 47.9±4.8 to 49.0±5.1 kg; time x treatment: P=0.78). In contrast, fat mass remained unchanged

in CON (11.3±2.6 to 11.3±2.8 kg), while a decrease was noted in INT (12.0±3.9 to 10.5±3.7 kg; time x treatment: P<0.01). BMD of the femoral neck decreased in CON (from 0.789±0.104 to 0.774±0.095 g/cm2), while being preserved in INT (from 0.803±0.058 to 0.809±0.066 g/cm2; time x treatment, P<0.01). No differences between treatments were observed for changes in BMD at the total hip, lumbar spine and whole body (time x treatment, P>0.05 for all). TBS increased from 1.38±0.08 to 1.40±0.09 in CON and from 1.46±0.08 to 1.47±0.08 in INT, respectively (time effect: P<0.01), with no differences between treatments (time x treatment: P=0.33). Serum P1NP concentrations decreased to a similar extent in CON (83.6±24.8 to 71.4±23.1 ng/mL) and INT (82.8±30.7 to 66.3±30.6 ng/mL; time-effect, P<0.001; time x treatment, P=0.22). Serum CTX-I concentrations did not change over time, with no differences between treatments (time-effect, P=0.08; time x treatment, P=0.58).

CONCLUSION: Frequent short bouts of jumping exercise combined with collagen supplementation beneficially affect femoral neck BMD in elite cyclists. As such, this intervention appears a promising strategy for mitigating the adverse effects of professional cycling on bone health.

PERI-EXERCISE L-CITRULLINE SUPPLEMENTATION REDUCED EXOGENOUS GLUCOSE UTILISATION, WITHOUT ALTERING ENDURANCE PERFORMANCE OR GASTROINTESTINAL DAMAGE IN MALE CYCLISTS

REYNOLDS, K.M., MACRAE, H.Z., FUNNELL, M.P., MEARS, S.A., BAILEY, S.J., JAMES, L.J.

LOUGHBOROUGH UNIVERSITY, UK

INTRODUCTION: Carbohydrate intake during endurance exercise is a recognised strategy to improve performance. Pre-exercise supplementation of l-citrulline has been demonstrated to improve endurance performance, VO2 kinetics and to reduce gastrointestinal (GI) symptoms/damage [1]. Arginine co-ingestion with carbohydrate during exercise has been shown to increase exogenous carbohydrate oxidation [2], but the effect of l-citrulline (which increases circulating arginine concentrations) in this regard remains unknown. Therefore, we examined the effect of adding l-citrulline to a carbohydrate supplement during prolonged cycling on exogenous carbohydrate oxidation, performance, and GI responses.

METHODS: Eleven trained male cyclists/triathletes (26 ± 6 y; 58 ± 5 ml/kg/min; 11 ± 5 h/week training) completed VO2peak and familiarisation trials, followed by two experimental trials involving 140 min cycling at ~55% Wpeak (preload) and a ~15 min time trial (TT). The study utilised a double-blind design and participants ingested glucose (60 g/h enriched with 0.2% [U-13C]-glucose) every 20 min either with (CHO+CIT) or without (CHO) the addition of l-citrulline (6 g/h). Expired breath samples were collected every 20 min to determine exogenous oxidation and venous blood samples/GI scales were collected at 0, 60, 140 min and post-TT.

RESULTS: TT performance was not different between trials (CHO 946 ± 90 s; CHO+CIT 923 ± 70 s; P=0.279), but there was a significant negative relationship between VO2peak and performance improvement in CHO+CIT (R=0.659; P=0.027). Mean 40-140 min (CHO+CIT 0.55 ± 0.09 g; CHO 0.62 ± 0.11 g; P=0.006) and peak (CHO+CIT 0.74 ± 0.12 g; CHO 0.82 ± 0.13 g; P=0.017) exogenous carbohydrate oxidation were reduced in CHO+CIT. Heart rate (P=0.347), RPE (P=0.948), overall GI comfort (P=0.804), plasma glucose (P=0.925) and plasma insulin (P=0.429) were not different between trials. Plasma lactate was higher in CHO+CIT post-TT (CHO+CIT 9.17 ± 3.74 mmol/L; CHO 7.36 ± 4.02 mmol/L; P=0.008). Sweat rate, dehydration accrued, plasma osmolality and plasma volume change were also not different between trials (P≥0.142), and neither were CD14 or IFABP-1 (blood markers of GI permeability/damage; P≥0.239).

CONCLUSION: The addition of l-citrulline to glucose consumed during prolonged cycling did not influence TT performance, but may be ergogenic in individuals with lower VO2peak scores. Additionally, these data suggest that the ability to use glucose provided in drinks during exercise is reduced when glucose is co-ingested with l-citrulline, although the mechanisms explaining these data are not clear. Finally, l-citrulline co-ingestion did not benefit GI symptoms (although these were low in both trials) or markers of GI damage (CD14 or IFABP-1), possibly due to the protective effect of carbohydrate intake on GI damage.

MOTOR UNIT MODULATION PARTLY EXPLAINS THE REPEATED BOUT PHENOMENON

HAYMAN, O., ANSDELL, P., ANGIUS, L., THOMAS, K., ŠKARABOT, J., HORSBROUGH, L., HOWATSON, G., GOODALL, S.

NORTHUMBRIA UNIVERSITY

INTRODUCTION: Unaccustomed eccentric exercise (EE) causes symptoms of exercise-induced muscle damage that are accompanied by changes in contractile properties and nervous system function, which persist for several days post-exercise[1]. Following a repeated bout of EE, the damage response is attenuated, however, it is unknown whether there is an alteration in motor unit (MU) behaviour during the performance of a repeated bout, which might contribute to the re-

peated bout phenomenon[2]. Accordingly, this study aimed to examine single MU properties during an initial and repeated bout of EE.

METHODS: Twenty-eight participants performed 2 bouts of 10 × 10 maximal lengthening dorsiflexion contractions four weeks apart. Maximal isometric voluntary toque (MVT) was measured pre- and post-EE. High-density surface electromyography (EMG) signals were recorded during trapezoidal contractions at 50% MVT. These were performed pre-EE, after set 5 (during) and post-EE. EMG signals were decomposed into individual MU discharge timings and were tracked across each time point. Mean MU discharge rate during the plateau of the trapezoidal contractions, along with recruitment and derecruitment thresholds were computed. Changes in outcomes variables within and between bouts were assessed with repeated measures analysis of variance.

RESULTS: Work done (1303 ± 404 vs 1401 ± 474 J; p=0.263) and the decrease in MVT immediately post EE (73 ± 11 vs 79 ± 12%; p=0.702) were similar in both bouts. MU data are reported for a preliminary cohort of 7 participants with a similar population of identified MUs (269 ± 9 vs 257 ± 11; p>0.05) and those tracked per participant in each bout (5 ± 2 vs 5 ± 4; p>0.05). For tracked MUs, the mean discharge rate at plateau increased during, and post the initial bout of EE (16.62 ± 3.60 and 17.32 ± 3.36 pps; p=0.022). The increase in discharge rate was attenuated following the repeated bout (15.09 ± 2.9 and 15.55 ± 3.5 pps; p=0.014). Furthermore, recruitment threshold (%Δ from baseline) was reduced during and post the first bout (–19.45 ± 10.26 and –28.4 ± 10.3%; p=0.011), but no differences were detected between bouts (–6.9 ± 4.83 and –7.7 ± 14.83%; p=0.286). A similar pattern was evident for de-recruitment thresholds, which decreased in the initial bout (–16.5 ± 9.1 and –24 ± 12%; p=0.003). Nevertheless, no difference was demonstrated between bouts (–12.3 ± 10% and –16.6 ± 12%; p=0.386).

CONCLUSION: During an initial bout of EE, increases in firing rate and reductions in recruitment and derecruitment thresholds were demonstrated. However, in a repeated bout, the changes in MU properties are attenuated. Such an adaptive response demonstrates preliminary evidence of a neural strategy to protect damage to skeletal muscle during a repeated bout of EE.

THE REDUCTION IN H-REFLEX AFTER SHORT MAXIMAL ISOMETRIC CONTRACTIONS IS MEDIATED BY PRESYNAPTIC INHIBITION MECHANISMS

KALC, M.

SCIENCE AND RESEARCH CENTRE KOPER

INTRODUCTION: Short maximal isometric contractions lead to an enhancement of motor performance, better known as Post activation potentiation (PAP). PAP muscle force enhancement can be attributed to different contractile and neural mechanisms. While the contribution of contractile mechanisms to PAP is well described in the literature, the neural mechanisms contributing to PAP are less well-studied. In particular, spinal mechanisms assessed using the H reflex are equivocal. Thus, the study aimed to investigate the effects of short maximal isometric contractions of plantar flexors on spinal mechanisms underpinning PAP.

METHODS: Fourteen males (age 21.9 ± 4.8 years) participated. They were instructed to contract their plantar flexors, exerting their maximal force for 10 s (PAP) or rest for 10 s (REST). Both exercise conditions (PAP and REST) were counterbalanced and conducted in a single visit with a 20 minutes rest between conditions. Soleus H-reflex, D1 presynaptic inhibition and Homonymous Ia facilitation (HF) were assessed in nine time points over 20 minutes after the maximal voluntary contraction. The soleus EMG signal was collected using a 64-channel matrix electrode (GR08MM1305, OT Bioelettronica, Italy). Peak-to-peak amplitudes were extracted from the electrically elicited responses. Data were analysed using repeated measures nested linear mixed effect models.

RESULTS: Immediately after the intervention, the H-reflex was significantly lower in the PAP condition compared to the REST condition ($P < 0.001$). Similarly, the D1 and FAC were, respectively, significantly lower ($P < 0.001$) and higher ($P < 0.001$) compared to the REST condition immediately after the intervention. The observed effects disappeared 2 minutes after the intervention.

CONCLUSION: The short maximal isometric contractions induced a significant drop in H-reflex amplitude, probably modulated by presynaptic inhibition mechanisms as assessed by D1 inhibition. Interestingly, the homonymous Ia facilitation HF was significantly increased. However, two minutes after the contraction, the observed spinal modulation in the PAP condition was not significantly different compared to the REST condition, suggesting that the effects of PAP on spinal modulation are short-lasting. Further analysis of the data from the multichannel electrodes is required to gain more insight into the effects of PAP on the modulation of motor unit firing rates after short maximal isometric contractions.

TRANSCUTANEOUS SPINAL CORD STIMULATION: PHYSIOLOGICAL SIMILARITIES WITH NERVE STIMULATION CONCERNING THE HPAD PHENOMENON

SORDET, J., VITRY, F., MARTIN, A., PAPAIORDANIDOU, M.

INSERM U1093

INTRODUCTION: Transcutaneous spinal cord stimulation (tSCS) elicits reflex responses in all muscles of the lower limb by stimulating the lower thoracic level. These posterior root muscle (PRM) reflexes are thought to share some physiological similarities with the H-reflex [1;2]. For example, they are sensitive to the homosynaptic post activation depression (HPAD) phenomenon when the inter-stimulus interval is very short (50ms) [2;3]. The HPAD results from the repeated solicitation of Ia afferences inducing a decrease in the amount of neurotransmitters available at the synapse and a subsequent decrease in the second reflex amplitude [4]. However, it is still unknown whether the amount of this inhibition is equivalent for the two types of reflexes. The aim of the study was to test whether these responses share the same physiological mechanism related to HPAD phenomenon.

METHODS: Sixteen subjects volunteered to take part in one experimental session consisting of stimulations of the lower thoracic level (to elicit PRM reflexes in the lower limb) and tibial nerve stimulation (to elicit H-reflexes and M-waves in the triceps surae muscles). EMG activity was recorded from the soleus muscle (SOL). Recruitment curves were built at rest for tSCS and tibial nerve stimulation. From these recruitment curves, the intensities permitting to elicit a SOL H-reflex and a SOL PRM reflex of the same amplitude (at the same % of Mmax) were determined. Paired-pulse stimulations were delivered with a 50-ms or 1-s inter-stimulus interval. H-reflexes were conditioned either with an H-reflex or with a PRM reflex of the same amplitude. In the same way, PRM reflexes were conditioned either with a PRM reflex or with an H-reflex of the same amplitude. For all the paired-pulse stimulations, conditioned responses were normalized with respect to the test responses, allowing to determine the degree of depression of the second reflex.

RESULTS: HCOND/HTEST (50ms: 0.05; 1s: 0.45) and PRMCOND/PRMTEST (50ms: 0.05; 1s: 0.51) were significantly lower when they were delivered at 50ms inter stimulus interval compared to 1s ($P<0.01$) but they were not significantly different between them when they were delivered at the same interval ($P>0.05$). For the series of stimulations evoked at 1s interval, the ratios HCOND/HTEST (0.45), PRMTEST/HTEST (0.48), PRMCOND/PRMTEST (0.51) and HTEST/PRMTEST (0.50) were not significantly different ($P>0.05$).

CONCLUSION: PRM reflexes are sensitive to the HPAD phenomenon like H-reflexes. The inhibition is more pronounced at intervals of 50ms than at 1s. For the different ratios at 1s, results show that the amount of inhibition due to HPAD is similar for the two types of responses. These first results corroborate previous findings reporting that tSCS effectively activates Ia afferences, at least for low reflex amplitudes.

OP-PN22 HIT – Interval Training

TWELVE WEEKS OF SPRINT INTERVAL TRAINING INCREASES PEAK OXYGEN UPTAKE BUT NOT PEAK CARDIAC OUTPUT IN MALES AND FEMALES

BOSTAD, W., WILLIAMS, J.S., VAN BERKEL, E., RICHARDS, D.L., MACDONALD, M.J., GIBALA, M.J.

MCMASTER UNIVERSITY

INTRODUCTION: Sprint interval training (SIT) improves peak oxygen uptake (VO2peak) but the mechanistic basis for this response is unclear. We recently reported that the improvement in VO2peak after 12 weeks of SIT was associated with an increase in peak cardiac output (Qpeak) in a group of young, untrained adults (n=15) (doi:10.1007/s00421-021-04714-4). An exploratory analysis suggested that mean Qpeak increased in the male but not female participants; however, that study was not powered to detect sex-based differences and did not incorporate other controls that are recommended for comparing responses between males and females (doi:10.1007/s40279-021-01435-8). The purpose of the present study was to explicitly compare the response of Qpeak between males and females to 12 weeks of SIT while employing best practice procedures for making sex-based comparisons.

METHODS: An a-priori sample size calculation (G*Power) based on data from our previous study estimated that a total of 14 participants were required to detect a partial eta-squared ($\eta 2p$) of 0.46 with 80% power at $\alpha=0.05$ for a 2x2 (time x group) mixed analysis of variance. A total of 20 participants with similar characteristics as in our previous study were recruited [10 males and 10 females (6 naturally cycling, 4 using a 2nd generation contraceptive)]. Males and females did not differ in baseline VO2peak expressed relative to fat-free mass (FFM; 55.1±9 vs. 49.1±8 ml/kg FFM/min, respectively, $p=0.13$). The two groups performed a similar number of training sessions (33±2) over 12 wk. Each 10-min session involved 3x20-s 'all-out' sprints interspersed with 2 min of unloaded cycling on an ergometer in addition to a brief warm-up and

cool-down. Before and after the intervention, a ramp cycling test to exhaustion was performed to measure VO2peak, followed ~10-min later by a short constant-load cycling bout at 90% peak work rate to determine Qpeak using inert gas rebreathing as in our previous study. Female participants were always tested in the low hormone phase of their cycle.

RESULTS: VO2peak increased after SIT (3.16±1.0 vs 2.89±1.0 L/min, p<0.001) with no sex x time interaction (η2p=0.014, p=0.61). Qpeak was not different after SIT (15.2±3.3 vs 15.1±3.0 L/min, p=0.85), and there was no sex x time interaction (η2p=0.007, p=0.72). Mean heart rate during training sessions was higher in female compared to male participants (83±5 vs 78±4% of peak heart rate elicited during the baseline VO2peak test, p=0.02).

CONCLUSION: In contrast to our previous study, Qpeak was unchanged after 12 weeks of SIT despite an increased VO2peak. The mechanistic basis for these responses warrants further research, but our data suggest that SIT may be associated with an enhanced capacity for oxygen extraction or muscle oxygen diffusion (doi:10.1152/ajpcell.00143.2022).

HIGH-INTENSITY INTERVAL TRAINING IMPROVES MITOCHONDRIAL FUNCTION SIMILARLY TO MODERATE-INTENSITY CONTINUOUS TRAINING BUT WITH BETTER ENHANCEMENTS IN VO2PEAK AND INSULIN SENSITIVITY IN TYPE 2 DIABETES

CORRAL-PÉREZ, J.1, ORTEGA-GÓMEZ, S.1, MARÍN-GALINDO, A.1, MONTES-DE-OCA-GARCÍA, A.1, CASALS, C.1, LARSEN, S.2, PONCE-GONZÁLEZ, J.G.1

1 UNIVERSITY OF CADIZ AND BIOMEDICAL RESEARCH AND INNOVATION INSTITUTE OF CADIZ 2 UNIVERSITY OF COPENHAGEN

INTRODUCTION: Type 2 diabetes mellitus (T2D) pathophysiology is characterised by skeletal muscle mitochondria dysfunction and insulin resistance (1). Even though different exercise models have been used in patients with T2D, like high-intensity interval training (HIIT) or moderate-intensity continuous training (MICT), which methodology is more effective on health-related outcomes is still unknown. The present study aimed to compare the effects of two different exercise training on skeletal muscle mitochondrial function, fat oxidation, cardiorespiratory fitness, insulin sensitivity, and body composition in patients with T2D.

METHODS: This study includes preliminary analyses from the EDUGUTION/APETEX/LIPIDOX randomized controlled studies. Twenty participants (55.26±8.92 years) were randomly allocated into HIIT (consisted of 10×1 intervals pedalling at 90% of peak power output, n=10, 4 females) or MICT (consisted of continuous pedalling at 10% above the first ventilatory threshold for 50 minutes, n=10, 4 females) training groups during 12 weeks, 3 times per week. Pre- and post-intervention testing included skeletal muscle mitochondrial leak respiration, state 3 respiration (CI), maximal state 3 respiration (CI+II) (high-resolution respirometry), basal fat oxidation, fat oxidation during exercise, and peak oxygen consumption (indirect calorimetry), insulin sensitivity (oral glucose tolerance test, OGTT), and body composition (bioelectrical bioimpedance). Results were analysed with a mixed factorial ANOVA with Bonferroni post hoc comparisons, significance was set at p<0.05.

RESULTS: All outcomes presented similar values at baseline between groups. The HIIT group significantly improved CI (+16.17±2.27 pmol s−1 [mg w.w.]−1, p<0.001) and CI+II (+34.28±2.64 pmol s−1 [mg w.w.]−1, p<0.001) respiratory states, absolute (+168.10±107.59 ml, p=0.048) and relative (+2.74±1.71 ml*kg-1*min-1, p=0.022) peak oxygen consumption, glucose levels at 180 min of OGTT (-34.50±4.68 1 mg/dl, p=0.027), body mass (-3.57±0.98, LA P), and fat mass (-2.33±0.36 kg, p=0.014; -1.29±0.11 %, p=0.049). The MICT group enhanced CI (+19.85±5.5 pmol s−1 [mg w.w.]−1, p=0.004) and CI+II (+38.54±12.23 pmol s−1 [mg w.w.]−1, p=0.016) respiratory states and fat mass (-2.48±0.82 kg, p=0.049; -1.46±0.28 %, p=0.009) but decreased basal fat oxidation (-12±1.2 mg/min, p=0.014). No time-by-group interactions were found for any of the variables.

CONCLUSION: The HIIT is a time-efficient strategy compared to MICT showing a similar improvement in mitochondrial oxidative phosphorylation and fat mass. Additionally, the 12-week HIIT intervention seems to achieve greater health gains than MICT on cardiorespiratory fitness and insulin sensitivity of adults with T2D.

ACUTE PHYSIOLOGICAL RESPONSES TO EFFORT-MATCHED HIGH INTENSITY INTERVAL TRAINING WITH AND WITHOUT BLOOD-FLOW RESTRICTION IN WELL-TRAINED CYCLISTS

SAUVÉ, B.A.J.M., VIKMOEN, O., RAASTAD, T.

NORWEGIAN SCHOOL OF SPORT SCIENCES

INTRODUCTION: Blood flow restriction (BFR) during endurance-type training has been shown to improve cardiopulmonary and muscular parameters [1, 2]. However, most studies have been performed using untrained participants and compared BFR versus a free-flow control condition based on the same absolute exercise intensity. The latter leads to an unrealistically low exercise intensity in the non-BFR condition which does not represent the intensity used during traditional training. Therefore, the aim of this study was to compare the acute metabolic and cardiovascular responses to interval training with BFR to effort-matched interval training without BFR in well-trained cyclists.

METHODS: In a randomized cross-over design, 10 well-trained cyclists (8 men, 2 women, VO2max: 66.1±5.8 and 56.4±7.7 mL/kg/min respectively) performed a session consisting of 6 intervals of 5 min cycling with 2.5 min of rest between each interval, both with BFR and without BFR (TRAD). An individualized occlusion pressure of 60% of full arterial occlusion pres-

sure was applied to the BFR cuffs during the intervals. Participants were free to adjust the power output during the intervals and were instructed to finish with the highest possible average power output across all 6 intervals. Metabolic and cardiovascular parameters were measured during all intervals. After each interval, the blood lactate concentration was measured, and participants were asked to rate the perceived exertion both in the cardiopulmonary system and in the legs. Paired Student's t-tests were performed to test for the differences between conditions. A statistical result of $p<0.05$ was considered significant. All data are presented as mean ± standard deviation.

RESULTS: Cycling power output was 48±4% lower during BFR compared to TRAD (148±31 vs 287±62 W respectively, $p<0.001$). BFR showed a 34±9% lower oxygen consumption compared to TRAD (2752±432 vs 4167±656 mL/min respectively, $p<0.001$) and a lower blood lactate concentration (3.5±0.7 vs 7.1±1.2 mmol/L respectively, $p<0.001$). Perceived exertion in the legs was higher following BFR compared to TRAD (Borg CR10: 8±1 vs 7±0 respectively, $p=0.004$) and overall cardiopulmonary exertion was lower (Borg RPE: 14±1 vs 17±1 respectively, $p<0.001$). The heart rate was 17±7% lower in BFR compared to TRAD (148±31 vs 167±40 bpm respectively, $p<0.001$) and the stroke volume was 10±13% lower (140±13 vs 169±6 mL respectively, $p=0.032$), resulting in a 26±11% lower cardiac output (20.5±3.2 vs 28.3±7.1 L/min respectively, $p<0.001$).

CONCLUSION: Effort-matched interval training with BFR reduced power output by almost 50% which in turn provided an attenuated metabolic and cardiovascular response compared to non-BFR conditions in well-trained cyclists. However, the stimuli for local muscular adaptations might be larger with BFR and further research should be conducted to elucidate this.

EFFECT OF EIGHT-WEEK SPRINT INTERVAL TRAINING ON THE LOCAL MUSCLE OXYGEN METABOLISM AND AEROBIC CAPACITY OF ELITE FEMALE BADMINTON PLAYERS

LI, Q.1, LIU, H.C.1, LENG, B.1, LIU, Y.1, BAO, D.1, LIU, H.Y.1, HO, I.2,3

1 BEIJING SPORT UNIVERSITY, BEIJING, CHINA 2 HONG KONG METROPOLITAN UNIVERSITY, HONG KONG, CHINA 3 ASIAN ACADEMY FOR SPORTS AND FITNESS PROFESSIONALS, HONG KONG, CHINA

INTRODUCTION: Elite badminton players are highly demanded on performing numerous high-intensity multi-shuttles sprints and jumps for saving and attacking. Sprint interval training (SIT) by alternating the interval duration, intensity, and sprinting formats, the specific interval patterns can mimic the intermittent stop-start nature and closely replicate the structure of a typical team and racquet sports game.

One of the critical determinants of aerobic performance is the oxygen utilization ability of skeletal muscles. Whenever an exercise condition creates an imbalance between oxygen supply and consumption (i.e. the use of an aerobic energy system), there are diverse changes in muscle oxygen content. Near-infrared spectroscopy (NIRS) can provide information regarding muscle oxygenation levels, oxygen depletion, and oxygen recovery rates during exercise.

Currently, the study of chronic physiological adaptations to SIT in elite badminton players is lacking. This study aimed to compare the effect of an 8-week SIT and continuous aerobic-based Fartlek endurance training on the aerobic capacity and muscle oxygen contents of elite female badminton players. The empirical findings of this study can inform the coaches and athletes if SIT can be an alternative format to continuous endurance training for aerobic enhancement. Furthermore, the mechanism of improvement is further explained by measuring physiological parameters related to oxygen intake, utilization, and recovery.

METHODS: Sixteen female badminton players volunteered to participate and were randomly assigned to the SIT group (n = 8) and the control (CON) group (n = 8). The SIT group performed SIT three times a week for eight weeks, while the CON group undertook fartlek running three times a week during the same period. All participants finished the incremental exercise test and arterial occlusion test to assess aerobic capacity and muscle oxygen conditions before and after the intervention. The non-clinical magnitude-based decision (MBD) and the precision of estimation were adopted to compare between and within the groups.

RESULTS: The results revealed that both SIT (3.7% and d = 0.49) and CON (1.6% and d = 0.43) enhanced VO2max. SIT induced a moderate decrease in oxyhemoglobin difference (△O2Hb: -8.2% and d = -0.76) and muscle oxygen consumption (mVO2: -8.2% and d = 0.77), and a moderate increase in super-compensation volume (△O2HbS: 8.6% and d = 0.69) as well as a small decrease in recovery time (TR: -4.9% and d = -0.29). CON only showed small decrease in △O2Hb (-2.0% and d = -0.31) and mVO2 (-1.9% and d = -0.29).

CONCLUSION: This study indicates that SIT potentially yields superior performance in local muscle utilization and recovery capabilities, and also the aerobic performance of elite badminton players than continuous Fartlek training. Bike-based SIT might be an alternative to provide trained athletes with an efficient and safe option for aerobic training.

EFFECT OF DYNAMIC ONSET THRESHOLD ON THE RATE OF FORCE DEVELOPMENT. A NEW PARADIGM.

STAFILDIS, S.1, BISCHOF, K.2, KÖNIG, D.2, BACA, A.1

UNIVERSITY OF VIENNA, AUSTRIA, CENTRE FOR SPORT SCIENCE AND UNIVERSITY SPORTS, 1DEPARTMENT OF BIOMECHANICS, KINESIOLOGY AND APPLIED COMPUTER SCIENCE 2DEPARTMENT FOR NUTRITION, EXERCISE AND HEALTH

INTRODUCTION: The determination of the force onset (FO) can affect the assessment of the rate of force development (RTD) in isometric explosive contractions [1,2]. Typically, a fixed FO either as absolute, relative or arbitrary value is used [1]. As "gold standard" stands the set of FOs manually, with low initial force value, in a non-filtered signal, with a custom-made dynamometer [1,3]. However, many laboratories are using commercial dynamometers with noisy force signal that need to be filtered [4]. Additionally, if numerous trials exist, the manual FO setting is labor intensive, time consuming [5] and could demonstrate poor reproducibility [6]. Furthermore, all fixed FOs, although objective, do not consider the contraction dynamics (velocity, acceleration), hence they do not assure identical dynamic starting condition. Therefore, this study aimed at investigating the effect of different dynamic onsets on maxRTD, time to reach maxRTD (TR) and the variability (coefficient of variation (CV)).

METHODS: Moment-time traces from knee extension contractions were used (trials=120, n=10). Data were filtered and seven dynamic FOs (100:50:400Nm/s) were applied to calculate the RTD from onset, every 1ms, until 250ms (250 intervals). We calculated mean, standard deviation and CV. Friedmans test and Wilcoxon posthoc with a Bonferroni correction was used for TR and maxRTD. Statistical Non-Parametric Mapping (SnPM{F}) with Bonferroni post hoc correction (a=0.0024) was used for the CVs for the different FOs and intervals.

RESULTS: Dynamic onset affected significant the maxRTD and TR (both x^2(6)=716.7, p<.001). Post hoc analysis showed significant increase in maxRTD and decrease in TR in all but for FOs 350vs400Nm/s (p=0.59) (maxRTD: 1633.3±22.9, 1703.4±21.9, 1760.7±21.2, 1804.7±20.9, 1843.5±21.1, 1877.7±21.3, 1905.4±21.2Nm/s and TR: 62.1±17.7, 57.7±15.7, 54.7±15.1, 52.5±14.7, 50.6±14.6, 48.9±14.4, 47.5±14.2 ms for 100:50:400Nm/s respectively). The SnPM{F} CVs comparison showed significant reduction clusters between 0-50, 120-199 and 220-250ms (p=.01). Post hoc comparison SnPM{F} only at 1-100ms area, showed significant lower CV clusters (~1-45ms) between FOs 100:50:400, 150:50:400, 200:300 Nm/s and non-beyond 250Nm/s.

CONCLUSION: The CV did not show any difference after 250Nm/s indicating that any further increase of the FO will not further reduce the CV. As expected, the dynamic FO affects the maxRTD and TR. Additionally, the respective force levels (0.2±1.6, 0.2±1.7, 0.6±1.6, 1.0±1.6, 1.4±1.6, 1.7±1.6, 2.1±1.7 Nm for 100:50:400Nm/s) remained low, indicating that the method can reliably assess RTD. This study provides the first evidence of a dynamic FO that considers also the dynamic status of the contraction.

AUTOMATED ANALYSIS OF MUSCLE ARCHITECTURE FROM B-MODE ULTRASONOGRAPHY IMAGES USING THE DL_TRACK SOFTWARE

RITSCHE, P., FRANCHI, M., FAUDE, O., FINNI, T., SEYNNES, O., CRONIN, N.

UNIVERSITY OF BASEL

INTRODUCTION: Apart from acquiring high quality images, a major difficulty in musculoskeletal ultrasonography is image data analysis. To assess muscle thickness, pennation angle and fascicle length in muscle ultrasonography images, often manual analysis is used. Yet, manual analysis is laborious, requires thorough experience and is somewhat subjective. We provide an openly available python package (DL_Track) to automatically analyze muscle architectural parameters in ultrasonography images or videos of human lower limb muscles.

METHODS: We trained two neural networks, one using the classic U-net architecture and the other using a U-net with a VGG16 pre-trained encoder, to detect muscle fascicles and aponeuroses using labeled musculoskeletal ultrasonography images. The images used in the training were collected from four different ultrasonography devices and included the vastus lateralis, gastrocnemius medialis, tibialis anterior, and soleus muscles. In total, 310 images were used for the fascicle model and 570 images for the aponeuroses model, which were augmented to around 1700 images per set. The datasets were randomly split into training and test sets using an 80/20 ratio. The best performing model was determined based on intersection-over-union and binary cross-entropy loss metrics calculated during training. We also compared the

neural networks predictions on an unseen test set of 35 images to manual analysis and two existing semi/automated analysis methods (SMA and Ultratrack).

RESULTS: The mean differences between DL_Track and manual analysis were -2.4 mm for fascicle length (95% compatibility interval = -3.7 to -1.2), 0.6° for pennation angle (-0.2 to 1.4), and -0.6 mm for muscle thickness (-1.2 to 0.002). The corresponding values comparing DL_Track with SMA were 5.2 mm for fascicle length (1.3 to 9.0), -1.4° for pennation angle (-2.6 to -0.4) and -0.9 mm for muscle thickness (-1.5 to -0.3) respectively. ICC values between DL_Track and Ultratrack were 0.19 (0.00 to 0.35) for medial gastrocnemius passive contraction, 0.79 (0.77 to 0.81) for medial gastrocnemius maximal voluntary contraction, 0.88 (0.87 to 0.89) for calf raise, 0.67 (0.07 to 0.86) for medial gastrocnemius during walking, 0.80 (0.79 to 0.82) for tibialis passive plantar and dorsiflexion, and 0.85 (0.83 to 0.86) for tibialis anterior maximum voluntary contraction.

CONCLUSION: The DL_Track python package is an open source, fully automated deep learning-based algorithm able to estimate fascicle length, pennation angle, and muscle thickness from single images or videos of multiple superficial muscles. The results obtained from DL_Track were in agreement with those produced by SMA or manual analysis for single images. Similarly, for videos, there was an overlap between the results produced by Ultratrack and DL_Track. DL_Track analyzes each frame independently of the previous frames, which might explain the observed variability in comparison to Ultratrack.

RELIABILITY OF A NOVEL SIMPLE METHOD FOR ULTRASOUND EXTENDED-FIELD-OF-VIEW IMAGES

BUNDSCHUH, L., FEICHTER, A., STAFILDIS, A.

UNIVERITY OF VIENNA

INTRODUCTION: To understand the architecture of a whole muscle, diagnostic imaging is of great importance. The gold standard for muscle visualization is magnetic resonance imaging or computed tomography (1). Both methods are costly and not universally available. Ultrasound (US) could be an alternative, but the probes are usually few centimetres long and therefore visualization of large muscles is difficult (2). Nonetheless, some commercial USs devices offer the extended-field-of-view (EV) option (2,3). AutoStitch is a free software solution to generate EV from multiple images of biological structures (4), but until now not in muscles. Therefore, the aim of this study is to assess the reliability of a new, simple and cost-effective method to generate EV images of human's muscles.

METHODS: We scanned (2x, scanning time ~5s) the vastus lateralis (VL) of 10 individuals from trochanter major to epicondylus lateralis with an US device (Artus ~60 Hz) at rest, in 3 different joint angles (70-90-110°). We placed 4 tape strips orthogonal to the VL line of action and measured the distances (1-2,1-3,1-4) with a measuring tape. We extracted video images, cropped (Irfanview) and stitched them together (AutoStitch) as EV. EVs were digitised (Tracker) and distances were estimated with the build in tool. The measured distance "1-4" was used to calibrate the EVs. We assessed with OneWay Anova the effect of joint rotation on measurement distance, with intraclass correlation coefficient (ICC) the Intrarater reliability and calculated the standard error of measurement (SEM) and the minimal detectable change (MDC95%). With parametric and non-parametric paired test, we assessed differences between measured and digitised distances.

RESULTS: There was no significant effect of joint rotation on the measured distances $F(2,27)=.01$ $p=.99$ $F(2,27)=.06$ $p= .99$ $F(2,27)=.83$ $p=.92$ (1-2,1-3,1-4 respectively). ICC was significant ($p<.001$) high (range .98-.99) for all distances and joint angles. SEM and MDC95% ranged from 0.05-0.16 and 0.13-0.44mm. Paired T-test showed no significant difference between measured and digitised distances (mean: 70°=9.6vs9.9, 18.8vs19, 27.2vs27.2; 90°=9.8vs9.8, 19vs19.1, 27.3vs27.3; 110°=9.7vs9.8, 19vs19.1, 27vs27mm; 1-2, 1-3, 1-4 resp.).

CONCLUSION: The novel EV method showed excellent intrarater reliability, low SEM, high sensitivity (MDC) and it was not affected by the joint rotation. The lack of differences in the distances 1-2, 1-3 indicates absence of image distortion due to image stitching. This method could allow researchers with common US devices to visualise and further understand the function of the whole muscles not only in rest but also under tension. Limitations of this method is the absence of 3D tracking position and the implementation with smaller US probes; however, this could be considered for further research.

ESTIMATING FASCICLE LENGTH FROM B-MODE ULTRASOUND IMAGES NEEDS RECONSIDERATION BEFORE COMMITTING TO AUTOMATED TRACKING ALGORITHMS

BISSAS, A., WALKER, J.

UNIVERSITY OF GLOUCESTERSHIRE; LEEDS BECKETT UNIVERSITY

INTRODUCTION: Static ultrasound (US) imaging is a popular tool when monitoring muscle architectural changes. A common limitation of static imaging is restricted field-of-view (FOV), which can be counteracted by methods which increase both image acquisition and analysis time (e.g., panoramic imaging). With a shift towards automated analysis using computer vision (e.g., deep learning), there is a need to identify the most optimal way of training algorithms to optimise fascicle length (FL) estimations from single static US images.

METHODS: B-mode US images of gastrocnemius medialis were obtained using a 50 mm linear array probe (Acuson P300, Siemens AG, Germany) from the muscle belly, with the probe aligned with the direction of muscle fibres. Twenty-five (from a subset of 301) images were analysed with ImageJ 1.52i (National Institute of Health, USA) to provide FL estimations using five methods: manual linear extrapolation (MLE), the methods of Kawakami (KAWA) et al. [1], Blazevich (BLAZ) et al. [2], and Finni (FIN) et al. [3], and a new approach which uses muscle thickness in the proximal region of the image divided by the sine of the pennation angle obtained from the distal region of the image (the "proximal-distal method" [PD]).

RESULTS: Mean ± Standard Deviation FL values for each method for the subset were: 64.61 ± 8.86 mm (MLE), 59.18 ± 9.81 mm (KAWA), 72.51 ± 14.44 mm (BLAZ), 69.46 ± 15.23 mm (FIN), and 65.20 ± 9.22 mm (PD). When comparing MLE with each of the other methods the PD returned a Bias ± Random Error of –0.59 ± 8.44 mm (ICC 3,1: 0.89), followed by KAWA with 5.43 ± 6.44 mm (ICC: 0.81), FIN with –4.85 ± 15.17 mm (ICC: 0.76), and BLAZ with –7.91 ± 15.03 (ICC: 0.66).

CONCLUSION: The use of two-dimensional US with restricted FOV for FL measurements still poses challenges with accuracy and reliability. The origin of the imprecision arises from the fact that there is not always a true value within the examined image to obtain. Even when a full fascicle is visible, its curvature alongside possible image distortion can affect the measurement. All aforementioned techniques are based on sound logic and geometric principles. Yet, they may provide for the same fascicle differences exceeding at times 20 mm whereas for a series of measurements their level of agreement may range from almost identical to highly dissimilar. The PD method showed overall strongest agreement and lowest systematic bias versus MLE which included several full fascicles in view. There could be a range of technical and anatomical of reasons for this, for example we scanned the gastrocnemius medialis whereas past studies established their estimation techniques on different muscles. As we are moving into the markerless era, more robust and streamlined ways of training tracking algorithms are needed.

RELIABILITY AND MEASUREMENT ERROR OF A MAXIMAL VOLUNTARY TOE PLANTARFLEXION MEASUREMENT PROCESS

ROMA, E., MICHEL, A., TOURILLON, R., MILLET, Y.G., MORIN, J.B.

UNIVERSITÉ JEAN MONNET SAINT-ETIENNE

INTRODUCTION: There has been a growing interest in the role of toe plantar flexor muscles in different contexts and populations such as sport performance (1) and older adults (2). However, directly measuring the force of the intrinsic muscles is impossible due to the extrinsic muscles' contribution in metatarsophalangeal toe flexion. Thus, measuring both is the best compromise according to the literature. This work aimed to investigate the test-retest reliability and measurement error of maximal voluntary isometric toe plantarflexion force (MVIF) and rate of force development (RFD) in healthy adults.

METHODS: A total of 26 (19 males) healthy adults participated in four sessions separated by 5 to 7 days. MVIF and RFD were measured at each session with a custom-built dynamometer. Using manual onset, RFD was quantified by both the impulse and the slope over 0-50ms, 0-100ms, 0-150ms, 0-200ms and 0-250ms time windows. For each outcome, we estimated the intraclass correlation coefficient (ICC) and standard error of measurement (SEM) from the agreement and consistency models. The bootstrap technique was used to provide the confidence interval for the standard error of the measurement and when the normality assumption was not met.

RESULTS: The ICC and the SEM agreement for MVIF along the perpendicular axis (Fz) were respectively 0.87 (95%CI: 0.76, 0.93) and 27 N (95%CI: 22, 32), while along the resultant of the perpendicular and anterior posterior axis they were 0.85 (0.73, 0.92) and 29 N (23, 35). We had some concerns about the normality assumption in the agreement models for Fz, hence we calculated the bias corrected accelerated confidence interval (BCACI) for ICCa, resulting in (0.65,0.93). The results of the consistency model were almost identical as the estimated variance for session was closer to zero. In addition, we found systematic bias on the mean between session 1 and 3, indicating a learning effect.

CONCLUSION: The measurement process was found reliable to assess MVIF but not RFD. In comparison to the relevant literature, the lower ICC agreement could be explained by the fact that the present study lasted longer. In fact, previous experiments used two sessions within one day [3], 1-5 days [4] and two weeks [5]. Considering the violation of the normality assumption, the uncertainty behind the ICCa estimate increased substantially, in fact the BCACI were sensibly wider. Finally, should the MVIFTOE method be used, a familiarization session is recommended to avoid bias induced by the learning effect and to reproduce the reliability of the present investigation. We emphasize that the results are population specific, e.g. they need to be confirmed in less coordinated (e.g. aging population) individuals.

LOW-LOAD BLOOD FLOW RESTRICTION TRAINING AND HEAVY SLOW RESISTANCE TRAINING IMPROVE CLINICAL OUTCOMES EQUALLY IN MALES WITH UNILATERAL PATELLAR TENDINOPATHY – A RANDOMIZED CONTROLLED TRIAL

HJORTSHØJ, M.H., JUNEJA, H., SVENSSON, R.B., LARSEN, F.K., LUNDGAARD-NIELSEN, M., HERZOG, R.B., PETERSEN, J., KJÆR, M., AAGAARD, P., MAGNUSSON, S.P., COUPPÉ, C.

BISPEBJERG-FREDERIKSBERG HOSPITAL, UNIVERSITY COLLEGE ABSALON, UNIVERSITY OF COPENHAGEN & UNIVERSITY OF SOUTHERN DENMARK

INTRODUCTION: Patellar tendinopathy (PT) is a debilitating overuse injury that is particularly prevalent in 'jumping sports' such as e.g., volleyball and basketball. PT is also one of the primary causes of reduced physical activity, which may contribute to reduced quality of life and lifestyle diseases. The current best treatment is heavy slow resistance training (HSRT); however, not all patients can cope with heavy exercise loads. Even with HSRT, the time to improve clinically from tendinopathy might be as long as 3-12 months. The use of low-load resistance training in combination with blood flow restriction (LL-BFRT) has been advocated as a clinically relevant rehabilitation tool since it does not require the large joint and tissue forces and because it might accelerate recovery. In this RCT, we investigated the rehabilitative effect of LL-BFRT compared with HSRT at 3, 6, 12 (primary endpoint) and 52 weeks (data still being collected) in males with chronic (> 3 months) unilateral patellar tendinopathy.

METHODS: Adult males were randomized to a 12-week rehabilitation program based on either LL-BFRT (n=16) or HSRT (n=20). Participants performed 3 weekly training sessions of which one was supervised by experienced sports physiotherapists. LL-BFRT exercised at 30% 1-RM but increased their arterial occlusion pressure (AOP) from 50% AOP at baseline to 80% AOP at 9 weeks. HSRT exercised at 55% of 1-RM with loads increasing to 80% of 1-RM at 9 weeks. Primary outcome was pain (numerical rating scale NRS, 1-10) during single-leg decline squatting (SLDS). Secondary outcome variables were Victorian Institute of Sports Assessment-Patella questionnaire (VISA-P) on function and symptoms and pain pressure threshold (PPT) measured by pressure algometry at 3, 6, and 12 (primary endpoint) weeks. A linear mixed effects model was used to analyze longitudinal changes in all outcome variables.

RESULTS: LL-BFRT and HSRT both improved based on the NRS SLDS. Values are reported as change from baseline [95% CI] to 3 weeks (LL-BFRT -0.8 [95% CI -1.6 – -0.1] vs. HSRT -1.1 [95% CI -1.6 – -0.7], 6 weeks (LL-BFRT -1.6 [95% CI -2.5 – -0.7] vs. HSRT -1.7 [95% CI -2.3 – -1.1]) and 12 weeks (LL-BFRT -1.9 [95% CI -2.7 – -1.0] vs. HSRT -2.0 [95% CI -2.7 – -1.2]) with no between-group differences. Similarly, VISA-P score improved with no between-group differences at 3, 6 and 12 weeks. PPT (symptomatic tendon) showed a non-significant decrease from baseline to 3 weeks but showed a significant increase from 3 to 6 weeks and 6 to 12 weeks with no group interaction at any timepoint.

CONCLUSION: LL-BFRT was not superior to HSRT but achieved comparable clinical improvements in the short- to mid-term. These results are comparable with other studies investigating exercise (HSRT) in the rehabilitation of chronic patellar tendinopathy. LL-BFRT is therefore a viable rehabilitation tool in the treatment of chronic patellar tendinopathy, and as an alternative to reduce peak loads.

ULTRASOUND CHARACTERISTICS OF THE SOFT TISSUES AROUND SACROILIAC JOINTS AND LUMBAR REGION IN PATIENTS WITH ANKYLOSING SPONDYLITIS

WANG, Y.G., LIN, H.C., WANG, H.K.

NATIONAL TAIWAN UNIVERSITY

INTRODUCTION: Ankylosing spondylitis (AS) is a type of axial spondyloarthropathy involves immune-mediated inflammation in the sacroiliac, vertebral, peripheral joints and entheses. Patients with AS typically present limited movement in the lumbar spine and thoracic cage, which may cause decreased physical activity. Masi proposed a pathogenesis that suggests the potential for maladaptation in response to mechanical stress in the soft tissues after the overactivation of immune response [1]. Previous ultrasonographic studies indicate that the maladaptation may be reflected in changes in morphological or mechanical profiles of the Achilles tendon at the enthesis, and the changes can serve as a powerful index for distinguishing spondyloarthropathy [2]. The morphomechanical properties of the ligaments and muscles in the lumbopelvic region may, therefore, potentially contribute to AS early diagnoses as these soft tissues are located near the sacroiliac joint where patients with AS first experience symptoms and are responsible for transmitting or producing mechanical forces that act on the posterior kinetic chain [3]. Therefore, the aims of this study were to investigate the musculoskeletal morphomechanical properties (i.e., the thickness and elastic modulus) and the total count of power Doppler signals near the sacroiliac joints in patients with AS and non-AS individuals.

METHODS: Twenty participants with AS [median age (interquartile range): 31.7 (11.04) years] and 19 controls [36.3 (10.5) years] with no AS history were recruited. Bilateral ultrasound image acquisition was performed, including the short posterior sacroiliac ligament, interosseous sacroiliac ligament, long posterior sacroiliac ligament, iliolumbar ligament, proximal piriformis muscle, and sacrotuberous ligament. The intraclass correlation coefficients (ICC) of ultrasound parameters, laboratory test results of human leukocyte antigen B27, C-reactive protein, and erythrocyte sedimentation rate, and self-reported physical and disease activity scores were also obtained.

RESULTS: The ligaments and piriformis muscle were thicker and stiffer (greater elastic modulus) in participants with AS than in non-AS participants (all p<0.01). The measurements showed good or excellent reliability (all ICC(3,1)>0.85). The numbers of power Doppler signals detected in the iliolumbar ligament, proximal piriformis muscle, and sacrotuberous ligament were higher in participants with AS than in non-AS participants (all p<0.001). A correlation was identified between disease duration and the elastic modulus of the piriformis muscle (r=0.640, p=0.003).

CONCLUSION: We conclude that the ligaments and proximal piriformis muscle of AS participants have increased thickness, elastic modulus, and power Doppler signal than those of non-AS individuals. These reliable findings may serve as potential markers for the early diagnosis of AS and for assessing medication effects.

SYSTEMATIC ULTRASOUND EVALUATION OF TENDON RECOVERY IN PATIENTS AFTER FINGER FLEXOR TENDON REPAIR

WANG, M.W.1, LEE, W.N.3,4, WANG, H.K.1,2

<1> NATIONAL TAIWAN UNIVERSITY COLLEGE OF MEDICINE; <2> NATIONAL TAIWAN UNIVERSITY HOSPITAL; <3, 4> THE UNIVERSITY OF HONG KONG

INTRODUCTION: Ruptures of the finger flexor tendon (FFT) are commonly known to cause hand disability, and postoperative tendon recovery is critical for restoring hand functions [1]. However, few studies have reported the physiological characteristics of the repaired FFT during its healing processes, such as gross morphology, mechanical property, mobility, and vascular status, which are considered important in the systematic ultrasound evaluation of Achilles tendon recovery [2] and may be related to functional outcomes. We hypothesized that the repaired FFT would show a larger size, weaker mechanical properties, poor mobility, and a more frequent blood flow signal than the healthy side under systematic ultrasound evaluation. We also hypothesized that the pinch strength and total range of motion (TROM) of the finger joints of the repaired FFT would be less than those of the healthy side, which would be correlated to the ultrasound parameters.

METHODS: This cross-sectional study recruited 10 adults (age: 37±14 years) who underwent unilateral single FFT repair within the past 6 to 22 months. B-mode images, shear wave elastography, radiofrequency data, and power Doppler images were collected from the bilateral FFTs for analyzing tendon thickness (millimeter), Youngs modulus (kilopascal), tendon gliding (millimeter), and the presence of blood flow signal. Functional outcomes, including pinch strength (kilogram) and TROM (degree), were also measured on both sides. The Wilcoxon sign-rank test was used to test the difference in all parameters (median [interquartile range]) between the sides, except for the blood flow signal (Fisher test). The Spearman correlation was used to determine the association between the ultrasound parameters and functional outcomes.

RESULTS: The affected side showed greater tendon thickness (4.3 [2.2] vs. 2.9 [1.0] mm, p=0.007), less tendon gliding (5.5 [3.3] vs. 9.7 [5.9] mm, p=0.009), more frequent blood flow signal (p=0.003), lesser pinch strength (7.0 [4.4] vs. 8.1 [5.4] kg, p=0.028), and lesser TROM (237.5 [43.8] vs. 287.5 [80] °, p=0.024) than did the healthy side. A strong correlation between the TROM and tendon gliding was found on the healthy side (ρ=0.742, p=0.014) but not on the affected side (ρ=0.195, p=0.590).

CONCLUSION: Except for the mechanical properties, the repaired tendons showed different physiological characteristics and poor functional outcomes from the healthy side, which is consistent with our hypothesis. The lack of correlation between tendon gliding and the TROM on the affected side may be attributed to postoperative adhesion, which interrupts the force transmission through the tendon. A longitudinal study with more participants is necessary to compare the physiological characteristics among different healing statuses.

ACHILLES TENDINOPATHY ALTERS THE LINK BETWEEN MUSCLE FORCE-SHARING AND SUBTENDON NON-UNIFORMITY

MYLLE, I., DEROOST, F., PETRELLA, D., BOGAERTS, S., CROUZIER, M., VANWANSEELE, B.

KU LEUVEN

INTRODUCTION: The Achilles tendon is the strongest and largest tendon in the human body and is connected and mechanically loaded through the force production of two individual muscles: the soleus (SOL) and the gastrocnemius (GAS). These muscles have shown independent actions on each subtendon with differential muscle force-sharing strategies [1] . Additionally, at the level of the Achilles tendon non-uniform displacement between tendon layers has been identified with the use of ultrasound speckle tracking [2]. The aim of this study was to investigate the influence of Achilles tendinopathy (AT) on the muscle-tendon interaction.

METHODS: Eight participants (4 AT: 1F & 3M, 4 healthy: 4M) performed a submaximal contraction (30%) of their maximal torque generating capacity with the foot fixated in 5 degrees of plantar flexion in neutral, abduction and adduction positions, while collecting intratendinous displacement by ultrasound speckle tracking. To gain insights into the muscle force distributions, dynamic bilateral heel raises -neutral, abduction and adduction positions- were performed. Triceps surae muscle forces were analyzed at 5 degrees of plantar flexion through experimentally measured kinematics and kinetics, and a dynamic optimization method (musculoskeletal modelling). The muscle-tendon interaction was estimated by the ratio between muscle force-sharing (SOL-to-GAS contribution) and the relative subtendon displacement (deep-to-

superficial). A value of 1 means that the imbalance of force produced by the SOL compared to the GAS generated a similar imbalance of intratendinous displacement. Shifting away from 1 represent a larger (<1) or smaller (>1) non-uniformity within the tendon compared to the muscle force imbalances.

RESULTS: An altered muscle-tendon interaction was found between the AT group and the healthy group. Patients with AT show more Achilles tendon non-uniformity than muscle force-sharing imbalances in the neutral (0.76 ± 0.36 [AT]; 0.86 ± 0.10 [healthy]), abduction (0.46 ± 0.21 [AT]; 0.81 ± 0.17 [healthy]) and adduction (0.97 ± 0.44 [AT]; 1.34 ± 0.42 [healthy]) positions. At the tendon level, less relative subtendon displacement was present in the AT group for all positions: neutral: 1.01 ± 0.23 mm [AT] vs 1.98 ± 1.28 mm [healthy], abduction: 1.31 ± 0.57 mm [AT] vs 1.50 ± 1.24 mm [healthy], and adduction: 1.60 ± 0.56 mm [AT] vs 1.99 ± 1.21 mm [healthy]. Additionally, a lower SOL-to-GAS contribution was found in AT (1.34 ± 0.92) compared to the healthy group (1.66 ± 0.58).

CONCLUSION: Patients with AT have less intratendinous shearing leading to an altered interaction of the muscle force-sharing and the pathological Achilles subtendons, which are known to function independently and individually. The influence of other factors on Achilles tendon functioning, such as the subtendon twist or the subtendons' mechanical properties remain unknown.

EFFECTS OF DIFFERENT HIP FLEXION ANGLES ON THE EXCURSION AND GLIDING OF THE PATELLAR TENDON LAYERS: PRELIMINARY RESULTS

SHIH, P.C., WANG, H.K.

NATIONAL TAIWAN UNIVERSITY

INTRODUCTION: Patellar tendinopathy (PTe) has high incidence and recurrence rates in jumping athletes and is often accompanied by pain and functional limitations. It is associated with excessive relative excursion and gliding between the layers of the patellar tendon (PT) [1]. The superficial layer of the PT is the extension of the rectus femoris coursing across the hip and knee joints. We hypothesized that controlling the hip flexion angle would affect the kinetics of the knee joint [2] and the excursion and gliding of the PT layers. Ultrasound speckle tracking (UST) can provide non-invasive and real-time soft-tissue images during dynamic motion [3]. Thus, we utilized UST to measure tendon motion in different hip joint flexion angles during knee flexion eccentric contraction. The results could provide insights into the etiology of PTe and help in the development of future clinical evaluation and treatment.

METHODS: Ten healthy men (age: 22.8±1.7 years) were enrolled. All of them were asked to perform knee flexion eccentric contraction in sitting and lying positions individually on an isokinetic dynamometer, with an ultrasound probe's upper edge placed against the patellar apex and parallel to the PT . The following parameters were compared: (1)excursion and gliding of the proximal superficial and deep layers of the PT (millimeter), (2) knee extension moment (newton meter), and (3) PT force (newton). Two-way repeated-measure ANOVA was utilized to compare the excursion and gliding values in the different layers and hip joint positions. A paired t-test was used to compare the biomechanical values between the two hip joint positions.

RESULTS: There was no significant difference in the excursion and gliding between the superficial and deep layers of the PT in the sitting position (p=0.54). In the lying position, there were significantly more distal excursion and gliding of the superficial layers than of the deep layers (p=0.015). In the kinetics analysis, there was no significant difference in the knee extension moment (p=0.155) and PT force (p= 0.165) between the two hip joint positions.

CONCLUSION: Changes in the hip flexion angle affected not only the kinetics but also the relative excursion and gliding of the PT. There were more relative excursion and gliding between the PT layers in the lying position during knee flexion eccentric contraction. Considering relative excursion as a mechanism of PTe, patients with PTe should avoid hip extension positions during rehabilitation programs.

DETERIORATING EQUIVALENCE IN PHYSICAL EDUCATION IN SWEDEN? USING SIBLING CORRELATION TO ESTIMATE THE EFFECT OF FAMILY BACKGROUND ON GRADES IN PHYSICAL EDUCATION BETWEEN 2000 – 2017

JANSSON, A.1, BJÄRSHOLM, D.2

1 MALMÖ UNIVERSITY, 2 LINNAEUS UNIVERSITY

Introduction

In physical education (PE), equivalence is a central goal in welfare states around the world. In Sweden, this means that the subject of PE should be equal and that schools are to compensate for students' different backgrounds, such as family background, socioeconomic and migration background. However, even if equivalence is a central goal, little is known about how equivalence in PE in Sweden has changed both during the last decades and in comparison to the students' average grade from all school subjects (so-called merit value). One well-established approach to examine equivalence in educational research is to analyze the correlation between full siblings' grades. Although this is a valuable approach to examine equivalence, no studies have used it in PE (Jansson et al., 2022). Using this approach, the aim of this study is to analyze how equivalence in PE in Sweden has changed, both over the last two decades and in relation to the students' merit value.

Methods

This study includes the total population of students (N=6,961,173) that were enrolled in Swedish schools between 2000-2017 in school year 6 and 9. The method is based on analyzing the correlation between full siblings that are born within a three-year period and their annually standardized grades in PE and merit value, using variance decomposition. One main advantage with this measure is that it considers all the aspects that full siblings share (e.g., socioeconomic, upbringing, living conditions and parenting). The analysis provides information about the extent of the total variation in PE grades and merit value that are explained by the family background of the students.

Results

In relation to the total variation in students' grades in PE and merit value, the proportion explained by variation between full siblings has increased between the years 2000-2017. Consequently, the results indicate that the importance of students' family background, over the past two decades, has become more important for both students' grades in PE and their merit value. However, the importance of family background has increased considerably more for students grades in PE, compared to their merit value. Furthermore, the largest increase in sibling correlation is found within the group of students born abroad.

Discussion

Preliminary findings indicate that equivalence in PE in Sweden has deteriorated between 2000 and 2017. Possible explanations are that: 1) schools, and in particular PE, has become worse at compensating for students with different backgrounds (e.g., socioeconomic); and 2) the students have become more heterogeneous, and as such making it more difficult to compensate for students' different backgrounds.

Jansson, A., Sundblad, G., Lundvall, S., Bjärsholm, D., & Norberg, J. (2022). Students' perceived learning in physical education: variations across students' gender and migration background in Sweden. Sport, Education and Society, 27(4), 421-433.Doi.org/10.1080/13573322.2021.1878129

THE PERCEIVED FUNCTION OF PHYSICAL ACTIVITY DURING THE SCHOOL DAY AMONG SWEDISH PRIMARY SCHOOL CHILDREN

HÖGMAN, J.

FACULTY OF ARTS AND SOCIAL SCIENCES

Introduction

Alarming reports of decreasing levels of physical activity (PA) among children has led to more interventions targeting children, not least in school. Such intrusions into children's lives are considered justified based on adults' knowledge about future risks that accompany lack of PA. However, children are not only future adults; they are also individuals with rights. There are studies highlighting children's perspectives, but these have mainly focused on children's experiences of PA. Much less explored are the functions children attribute to PA. The purpose of the study was therefore to investigate how a group of primary school children in Sweden characterise their use of PA during the school day.

Methods

The study builds on qualitative data from 15 focus groups with a total of 63 participating children aged 8-13 years. Participants were recruited from schools in four different locations in central Sweden. The analysis, which was carried out using reflexive thematic analysis, was based on the phenomenological idea of corporeality as a spectrum between corporeal objectivity and subjectivity.

Results

Three overarching themes were constructed to illustrate how children characterise their use of PA in the school context: PA for a healthy body (the body as object), the body calling for attention (the body as subject) and the moving body and the healthy mind (between subject and object). When the body was presented as an object, the children's statements about the use of PA reflected discourses about the importance of movement for their health, in the short and long term. When the body was discussed as a subject, the children stressed how movement became their response to bodily sensations such as "ants in their pants" that arose during extended periods of sitting still. In the children's descriptions of needing to move in order to, for instance, "clear their thoughts" or "not go crazy", the body was located in the space between object and subject.

Discussion

Results show that children perceive that PA can be used both to satisfy their direct bodily desires and to promote their health, cognition and well-being. The children in the study are in a period of life where one foot is clearly planted in a child's physicality, where they are reminded through their bodies of the need for movement in order to develop. The second foot, meanwhile, is stepping through a socialization process in which the body is increasingly regarded as needing care and discipline. A consequence of interventions focusing too heavily on the body as an object is that children risk being alienated from their bodies, thus preventing them from learning to use their bodies to interact with the environment. In light of the increased need for efforts to promote children's PA, it is important to create conditions for PA that affirm children's bodily subjectivity.

PUPILS' PERSPECTIVES ON RACISM AND ANTI-RACISM IN PHYSICAL EDUCATION: FINDINGS AND RECOMMENDATIONS FROM A SYSTEMATIC LITERATURE REVIEW

ABEL, L., VOGT, T.

GERMAN SPORTS UNIVERSITY COLOGNE

Introduction

Sport in all social forms is characterized by racist structures and incidents, also experienced by children and youth. Physical education (PE) can be an area to fight racism but can also be an environment where racism is (re)produced. The perspective of pupils is crucial in teaching research as they are the primary individuals experiencing teaching and learning. As a result, they can offer valuable insight into both successes and challenges encountered. The objective of this study was to conduct a systematic review to find out the extent and quality of national (German) and international publications on racism and anti-racism in PE, considering pupils' perspectives.

Methodology

The procedure of the systematic review, following the PRISMA standard, had a four-step approach: (1) Searching for publications in 11 electronic databases with 12 keyword combinations, in German and English. (2) Selecting studies based on five inclusion criteria a) peer-reviewed journals b) English or German full texts; c) participants were pupils, teachers, or researchers; d) publications involved racism or anti-racism in PE e) considering a pupils' perspective. (3) Quality assessment using Critical Appraisal Skills Programme (CASP) and Mixed Methods Appraisal Tool (MMAT) and, thus, (4) descriptive analysis and thematic analysis (i.e., template analysis and elements of reflexive thematic analysis).

Results

A total of 5213 publications was found of which 16 qualified for inclusion. Two of them had a theoretical approach, 13 used qualitative methods, and one source had a mixed-method approach. All publications came from English-speaking countries and different approaches on how to define racism were found. Every publication could be attached to the top two out of three quality categories using CASP and MMAT. During the thematic analysis, five themes could be constructed, of which the 2 most prominent are now presented here: (1) "Racism in PE: What pupils experience". Pupils report their (racist) experiences of discrimination in PE, sport, and everyday life. These are often classified by the researchers as racial stereotypes and prejudices, everyday racism. (2) „What PE teachers can/should do?" The articles contain ideas and demands on how teachers can meet the challenge of racism in PE. These range from concrete recommendations for teachers to demands for nationwide teacher training and curriculum reforms.

Discussion

Enlightening international literature was found, but despite Germanys historical responsibility in this matter, no national (German) publication was found. Since the global phenomenon of racism differs locally, it seems necessary to conduct a survey with pupils in Germany as well, to identify their racist experiences, racist knowledge, and anti-racist potential, too. This would allow to formulate demands on teacher training and politics in Germany.

EXPLORING ADOPTION OF GAMES-BASED PHYSICAL LITERACY CONCEPTS IN PRACTITIONERS ACROSS THE UK

WING, K., DE STE CROIX, M., ROBERTS, W.M., BAKER, C.

UNIVERSITY OF GLOUCESTERSHIRE

INTRODUCTION: It is widely proposed that practitioner education could mitigate declining Physical Literacy (PL) and Physical Activity (PA) levels [1]. Boing is a workshop-based intervention that aims to help practitioners develop children's PL through active play. Preliminary studies indicated improvements following the workshop in key attributes: perceived knowledge and confidence [2]. It is unknown if these improvements were retained longitudinally and led to adoption of the intervention's concepts in various organisations. Therefore, the aim of this study was to complete a post workshop

follow-up to explore the perceived knowledge of and confidence to deliver PL and if these variables related to adoption in different organisations.

METHODS: 926 practitioners from 45 organisations were recruited. Two sequential validated questionnaires that explored perceived knowledge and confidence were previously completed prior to and immediately post a 90-minute interactive online workshop. A follow up questionnaire 6-months post intervention was implemented to explore improvements longitudinally. Variables were scored on a Likert scale (1-very poor, 5-very good). Potential changes elicited were assessed using Wilcoxon signed-rank tests for non-parametric data. Rank-biserial correlation [r] was utilised to calculate the effect size based on existing criteria [3]. Chi-square tests explored differences between organisations post/follow-up and pre/follow-up. The alpha level was set at 0.05 a priori.

RESULTS: 738 participants completed pre/post questionnaires, 185 participants (25%) completed all questionnaires (organisations: community focused n=26, sport n=17, education providers n=124, wider facilitators n=18). Statistically significant decreases in post/follow-up perceived knowledge (r= 0.87 [95% CI = 0.80 – 0.92]) and confidence (r= 0.55 [95% CI = 0.36– 0.70]) were evident. However, perceived knowledge and confidence 6-months post remained higher than pre-workshop levels with statistically significant increases ($p<0.001$) and large positive effect sizes evident: perceived knowledge (r= 0.86 [95% CI = 0.80 – 0.91]) and confidence (r= 0.81 [95% CI = 0.72 – 0.90]). Overall, 90% of participants intended to adopt post workshop with 65% stating adoption had occurred by 6 months. Significant differences in adoption were reported between organisational groups ($p=0.01$) where sports organisations reported the highest adoption rate (90%).

CONCLUSION: Perceived knowledge and confidence was retained 6-months after the intervention however decreases were evident. Post intervention support may be required to address this decline. Importantly the workshop resulted in adoption of PL concepts, particularly in sports organisations. However, 35% of participants who intended to adopt did not. Further investigation is needed explore reasons for the decrease in perceived knowledge/confidence longitudinally and the differences between organisations in adoption if the intervention is to be implemented and maintained.

ITALIAN VALIDATION AND STANDARDIZATION OF TGMD-3: A TOOL FOR ASSESSING AND PLANNING TEACHING

DANNA, C.1, CARLEVARO, F.2, MAGNO, F.3, MAGISTRO, D.4

1 PEGASO UNIVERSITY 2 POLO UNIVERSITARIO ASTI STUDI SUPERIORI 3 UNIVERSITY OF TORINO 4 NOTTINGHAM TRENT UNIVERSITY, UK

INTRODUCTION: Gross motor skills play a crucial role in the growth and development of children. These skills refer to goal-directed movement patterns involving locomotion, large whole-body movements and stretches. By evaluating a childs gross motor skills, it is possible to detect any potential delays and implement effective programs. The purpose of this research was to validate and standardise the Test of Gross Motor Development-3 (TGMD-3) in a large sample of Italian pre-school and primary school students.

METHODS: The study included 8,500 children (250 males and 250 females in each group) aged 3-11 years in 17 age groups (6-month intervals except last group with 9-month interval). The study included children over the age of 11 years to encompass the entire primary school cycle and provide a benchmark of gross motor skills for the incoming assessment in secondary school. The TGMD-3 assesses gross motor skills across two domains: locomotor skills and ball skills. Participants completed one practice trial and two formal trials, observed by two testers (agreement rate over 95%). The study evaluated the validity and reliability of the TGMD-3 and investigated gender differences through ANOVA analysis ($p<.05$).

RESULTS: The results of both exploratory and confirmatory factor analyses confirmed the two-factor structure of the TGMD-3, with all factor loadings being significant at $p < .001$. Additionally, the study found strong positive correlations between the test and retest of the TGMD-3s sub-scale, with ICC values ranging from .979 to .997 for each age groups. The one-way ANOVA analysis revealed significant differences for most of the age groups. As a result, the table converting raw scores into percentile ranks, scalar scores, and confidence intervals was divided by gender for both subtests, in contrast to only the "Ball skills" subtest in the American version.

This study was published by Erickson (2023) in an academic book that includes a digital platform (TEO-Test Erickson Online) that provides support in the notation and scoring process through a "Wizard" feature. The platform generates a final report for each child evaluated, including descriptive terms for standard scores. The manual offers guidance for interpreting evaluation data, to identify strengths and weaknesses to design effective learning environments.

CONCLUSION: The TGMD-3 has strong validity and reliability for measuring gross motor skills in children across age groups. It assesses childrens competence in specific skills, sub-scales, and overall, and can aid in creating personalized educational programs and informed curricular decisions.

OP-AP09 New Olympic Sports

SPORT CLIMBING DETERMINANTS AND FUNCTIONAL TESTING METHODS: A SYSTEMATIC REVIEW-BASED PROPOSAL FOR STANDARDISED FUNCTIONAL PERFORMANCE ASSESSMENT

FAGGIAN, S., BORASIO, N., VECCHIATO, M., BATTISTA, F., QUINTO, G., DUREGON, F., ERMOLAO, A., NEUNHAEUSERER, D.
UNIVERSITY OF PADOVA

INTRODUCTION: Lead climbing, bouldering and speed climbing are becoming incredibly popular both in the general population and among athletes. Indeed, sport climbing made its debut in the 2021 Olympics Games in Tokyo. However, no consensus exists regarding evidence-based sport-specific performance evaluation; therefore, the present systematic review aims to provide an overview of climbing performance determinants and evaluation methods by analysing climbers of different ability levels.

METHODS: A systematic search of PubMed, Scopus, and Web of Science was performed. Studies providing the self-reported climbing ability associated with different functional outcomes in groups of climbers of contiguous performance levels were included. Functional components of interest were cardiorespiratory endurance, muscular strength, muscular endurance, muscular power, flexibility, balance, and anthropometric characteristics assessed by general or climbing-specific functional tests. Concurrent and construct validity as well as reliability have been evaluated for qualitative test assessment.

RESULTS: A total of 1789 articles was retrieved and 70 studies were finally included. Various methods have been proposed to evaluate determinants of sport climbing. While test validity evaluations were available, reliability measures have been rarely provided. Climbing-specific assessments were able to discriminate better climbers of different levels when compared to general functional tests. Validity resulted high for climbing-specific cardiorespiratory endurance, muscular -strength, -endurance and -power, although the reliability analysis of the former was insufficient. Climbing-specific assessment of flexibility resulted in high reliability, but moderate validity, whereas balance showed low validity. Regarding anthropometric characteristics, huge conflicting evidence is depicted since many studies found results not supporting a significant impact of these parameters on climbing performance.

CONCLUSION: While some conclusive evidence can be drawn for cardiorespiratory endurance, muscular -strength, -endurance, and -power assessment, by contrast flexibility, balance, and anthropometric characteristics are still far to be topic on fire in sport climbing and need further specific scientific evaluations. This review also provides a proposal for an evidence-based functional performance assessment protocol for sport climbers, which considers (i) the available test validity and (ii) reliability for the broadest range of climbing performance levels, (iii) the simplicity of standardisation of testing procedures, and (iv) the minimum financial and equipment constraints. While athletes and coaches may engage in evidence-based and standardised evaluation methods, researchers should design specific large-scale trials as a resource in providing additional, homogenous, and comparable data in order to improve scientific evidence and professionalism in this popular sport discipline.

SMART TRUCK: CLASSIFYING SKATEBOARD TRICKS WITH A CONVOLUTIONAL NEURAL NETWORK BASED ON MOTION DATA

WESTENBERGER, E., HOLLAUS, B., FREITAS, G., FRESEN, L.
MCI

INTRODUCTION: In the fitness community, quantifying activities with apps and wearables rose in popularity throughout the last decade. In sports like running or cycling, these digital technologies are ubiquitous while fun sports are not yet as present. The Smart Truck project aims to change that for skateboarding by enabling the classification of tricks. Studies on motivation behind fitness app usage show that achievement oriented members of the running community benefit most from the tracking features of such apps [1]. Skaters could use this technology to keep track of their skill progression or to compete in challenges.

METHODS: In an experiment, motion data of the rear axis of a skateboard was recorded with an IMU at a sample rate of 120Hz while skaters were performing the following tricks: "Ollie", "180 Front-side", "180 Back-side", "360-flip", and "Kick-flip". While performing the tricks, orientation, angular velocity and magnetic flux density were recorded. In the post-processing phase, the relevant data around the pop was extracted to an array with the dimensions of 9x120 elements. The 9 rows represent orientation, acceleration and magnetic flux density for all axis. The 20 data-points prior and the 100 data-points after the pop are saved to a .csv file. The dataset was split into parts containing 80% and 20% of the samples for training and testing respectively. To classify each trick, the neural network was designed with a combination of linear, max pooling, and one dimensional convolution layers. For optimization, the Adam optimizer was used [2].

RESULTS: The accuracy score of the model created for this project amounts to 96.84%. With a batch size of 10 samples per step and 80 steps per epoch, 5 subsequent loss values of lower than 0.2 were achieved after 6 epochs. The tricks with the lowest and highest mean confidence scores respectively are the "360-flip" with 77% and the "Kick-flip" with 95%. The tricks "180 front-side" and "180 back-side" ranked lowest in precision both with a score of 94% compared to the tricks "Ollie" and "Kick-flip", both with a score of 100%.

CONCLUSION: The results show that it is possible to create a model that is capable of classifying skateboarding tricks based on motion data. Although the model performs classification with sufficient accuracy, the results have limitations. The major limitation is the dataset, as it was unbalanced and of limited variety. In the future the dataset could be improved by including more recordings from a broader demography of skaters. As the project was intended as a proof of concept, the results achieved with the current dataset were able to demonstrate the feasibility of a digital gamification platform for skateboarding. This outcome could inspire similar products, leading to a stronger representation of funsports in the digital market.

COMPETITIVE SKATEBOARDING– INTERDISCIPLINARY PERSPECTIVES ON THE DISCIPLINE PARK

BÜSCHER, B., CHARLY, M., SIMBAÑA ESCOBAR, D.

1 TU DORTMUND, 2 UNIVERSITÉ DE ROUEN, 3 FRENCH ROLLER & SKATEBOARD FÉDÉRATION

Theory

As a theoretical figure, Skateboarding stands as an informal subculture building around the movement patterns of a roll sport in connection to the attribution of urban spaces, where the mostly adolescent participants reproduce an associated lifestyle (Borden, 2019). However, the integration into the Olympic Summer Games 2020 (2021) in Tokyo has triggered ongoing tendencies around the subculture's "sportisation" (Kilberth & Schwier, p. 11) resulting in the incorporation of existing sports associations as well as the establishment of training facilities and programmes. Ongoing debates not only cover the partial transformation of the informal practice into more standardised and competitive log-ic of sport, but furthermore focus on the particularities of the newly evolved differentia-tions (Atencio et al., 2018).

Method

Focusing on the olympic discipline Park, research focuses on the terrain's structure con-cerning the form and arrangement of ramps, obstacles and intersections, as well as the adaptive movement patterns in 45-second runs during which the athletes aim to perform a condensed presentation of a variety of tricks.

The WST Park World Championship 2022 (executed in February 2023) was analysed, data was collected from the public results (rawmotion.com/WSTWC22S).

Mean values of age and number of nationality participant was calculated for each phase (qualifiers, quarter, semi-final, final). R Studio was used to performed the statistical anal-ysis. Kruskall Wallis test was chosen to compare the mean values because data was non parametric.

Results

183 Athletes (65 F and 126 M) participated at the WST with four pressed athletes directly qualified directly to quarter final. Female athletes were younger that male athletes (16.6 □□3.62 vs. 21.1□□6.89, p<0.001□□□Nationality have an influence in the final score for male (F=73.2, p<0.01,□2= 0.40) and female (F=37.5, p<0.05,□2= 0.37). Only 3 nations were rep-resented at the final (M: USA, AUS and BRA, F: GBR, JPN and USA).

Discussion

Skateboarding is growing around the world, especially among young female athletes whose total number is lower than of male athletes. There were more nationalities repre-sented (39 vs. 22) despite the nations obtaining the best score were the nations where the skateboard culture was largely represented. Countries need funding for new skate-parks matching Olympic norms to help athletes to improve training programmes and pre-pare for the competition. Stakeholders in each country need to continue to develop train-ing programs and promote the young talents in skateboarding competition.

DOES THE SUCCESS RATE OF OFFENSIVE PLAYS IN 3X3 BASKETBALL VARY WITH THE TYPE OF OFFENSE AND AGE/SEX CATEGORIES?

MADARAME, H.

SHIGAKKAN UNIVERSITY

INTRODUCTION: 3x3 is a new basketball discipline that has become one of the Olympic sports since the Tokyo 2020 Olympic Games. While the number of studies on 3x3 basketball has been growing in recent years [1-4], research in this field is still in its infancy. More in-depth studies will help to develop this relatively new sport. The purpose of this study was to compare the success rate of offensive plays in 3x3 basketball by the type of offense and age/sex categories.

METHODS: This study analyzed the FIBA 3x3 World Cup 2019 and the FIBA 3x3 Under-18 World Cup 2019. Each play was coded by the researcher from game footage using a notational analysis method. All offensive plays were classified as a transition offensive play (TOP), a check-ball offensive play (CBOP), or an offensive rebound offensive play (OROP). An offensive play that resulted in a successful field goal or earned a free throw was considered successful. A Pearson's chi-squared test was used to compare the success rates of the offensive plays. Multiplicity was adjusted by the Benjamini & Hochberg method to maintain a significance level of $P < 0.05$.

RESULTS: In all four categories (senior men, senior women, under-18 men, and under-18 women), TOP occurred with the highest frequency (55.1-57.5% of the totals), followed by CBOP (28.1-31.2%) and OROP (11.9-14.7%). The success rate of OROP (39.2-49.2%) was significantly higher ($P < 0.05$; effect size = 0.07-0.14) than that of the TOP (28.5-36.4%) and CBOP (32.1-35.0%) in all four categories. While the success rate of CBOP did not differ among the four categories, the success rate of TOP was significantly higher ($P < 0.05$; effect size = 0.04-0.09) in the men's tournament (34.6-36.4%) than in the women's tournament (28.5-31.1%). The success rate of OROP was significantly lower ($P < 0.05$; effect size = 0.08-0.10) in the under-18 women's tournament (39.2%) than in the other three categories' tournaments (47.3-49.2%).

CONCLUSION: Increasing the success rate of TOP is essential for winning a game because TOP accounts for more than half of the total offensive plays. The success rate of TOP was lower in the women's tournament than in the men's tournament; however, the lack of sex differences in the success rate of CBOP suggests that there is still room for women to increase the success rate of TOP.

EFFECTS OF PROTEIN SUPPLEMENTATION, COMBINED WITH HIGH-INTENSITY FUNCTIONAL TRAINING, ON THE PLASMA AMINO ACID PROFILE, BIOCHEMICAL AND HEMATOLOGICAL PARAMETERS IN TRAINED MEN AND WOMEN

KARPOUZI, C.1, KOSMIDIS, I.1, PETRIDOU, A.1, VIRGILIOU, C.2, GIKA, H.2, THEODORIDIS, G.2, BOGDANIS, G.C.3, MOUGIOS, V.1

1ARISTOTLE UNIVERSITY OF THESSALONIKI, 2ARISTOTLE UNIVERSITY OF THESSALONIKI, 3NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS

INTRODUCTION: High-intensity functional training (HIFT) is an effective form of training that includes multijoint aerobic and resistance exercises. Despite its popularity, few studies have examined adaptations to HIFT and even less is known regarding dietary guidelines to optimize HIFT. Protein supplementation has been extensively investigated in resistance training, but there is limited evidence regarding its effectiveness in HIFT. Additionally, few studies have examined egg white as a protein source. Hence, the aim of this study was to examine the effects of two forms of protein supplementation (egg white and whey), combined with HIFT, on the plasma amino acid profile, biochemical and hematological parameters of trained individuals.

METHODS: Thirty trained volunteers (20 men and 10 women), aged 23-55, underwent 6 weeks of HIFT while receiving 0.6 g/kg/day of egg white protein (E), whey protein (W), or maltodextrin (placebo, P) in a single-blinded, randomized, triple-crossover, and counterbalanced design, with 2 weeks of washout between supplements. Participants received isoenergetic dietary plans providing 1 g/kg/day of protein throughout the study. Before and after each intervention period, participants provided fasting venous blood samples at rest. Full blood count, serum glucose, triacylglycerols, total cholesterol (TC), HDL cholesterol, LDL cholesterol, urea, creatinine, creatine kinase, γ-glutamyltransferase, cortisol and testosterone were measured in automated analyzers. Plasma amino acids were measured with liquid chromatography – mass spectrometry. Data were analyzed by 3-way ANOVA (supplement x time x sex) with repeated measures on supplement and time. Statistical significance was set at $p < 0.05$.

RESULTS: Urea and TC differed between supplements, with urea being higher in E and W, compared to P, and TC being higher in P compared to W. Leukocyte and platelet counts increased, whereas erythrocyte count, hemoglobin, hematocrit and glucose decreased with training. There were also expected differences between sexes in hematologic and biochemical parameters. Regarding the plasma amino acid concentrations and percentage distribution, there were no differences between supplements. However, there were many effects of training (including increases in Leu, Pro and Trp, and decreases in Arg, Asn, Gln, Gly and Lys, in terms of both concentration and percentage) and differences between sexes, including a higher total plasma amino acid concentration in men compared to women (2.57 ± 0.50 vs 2.35 ± 0.46 mmol/L, mean ± SD).

CONCLUSION: Short-term HIFT caused several changes in hematologic and clinical-chemistry parameters of trained men and women (notably hemodilution), whereas protein supplementation affected only serum, urea and TC. Additionally, training, but not supplementation, had profound effects on the plasma amino acid profile. These novel findings show that training is a stronger modifier of blood biochemistry and, in particular, amino acid metabolism than nutrition.

EFFECTS OF A MULTI-INGREDIENT PROTEIN, Ω3 FATTY ACID, AND VITAMIN D SUPPLEMENT, COMBINED WITH HIGH-INTENSITY FUNCTIONAL TRAINING, ON EXERCISE PERFORMANCE AND THE BLOOD FATTY ACID PROFILE

KOSMIDIS, I.1, KARPOUZI, C.1, PETRIDOU, A.1, BOGDANIS, G.C.2, MOUGIOS, V.1

1. ARISTOTLE UNIVERSITY OF THESSALONIKI, 2 NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS

INTRODUCTION: High-intensity functional training (HIFT) is a relatively new training modality, based on the CrossFit training principle, which emphasizes functional movements via aerobic and resistance exercises. HIFT has been reported to improve muscle performance. Whether dietary supplements improve adaptations to HIFT has not been adequately researched. Protein supplementation is well documented as an ergogenic aid in resistance training. Additionally, there is some evidence that ω3 fatty acids and vitamin D, in addition to their beneficial effects on health, may increase performance. However, there is no evidence for their effectiveness in combination with HIFT. As part of a broader project, the aim of the present study was to investigate the effects of HIFT in combination with a multi-ingredient supplement containing protein, ω3 fatty acids, and vitamin D, on exercise performance and the blood fatty acid profile.

METHODS: Twenty-one trained adults (13 women and 8 men), aged 19-35, underwent 6 weeks of HIFT while receiving the experimental supplement (E; 0.6 g fish protein/kg body mass, 1.8 g ω3 fatty acids, and 20 μg vitamin D daily), whey protein (W; 0.6 g/kg/day), or maltodextrin as placebo (P; 0.6 g/kg/day) in a single-blinded, randomized, triple-crossover, and counterbalanced design, with 2 weeks of washout between supplements. Participants performed HIFT 3 times a week, while following a mixed, isoenergetic diet providing 1 g/kg/day protein throughout the entire study period. The internal load of training sessions was assessed during the first and last week of supplementation by heart rate (HR) telemetry. The blood fatty acid profile was determined pre- and post-supplementation using gas chromatography. Data were analyzed by repeated-measures 3-way ANOVA (supplement x time x sex). Statistical significance was set at $p < 0.05$.

RESULTS: Exercise time during each session increased from 37.3 ± 6.4 min at the beginning to 39.7 ± 7.6 min at the end of each intervention period ($p = 0.014$) due to more repetitions to exhaustion, with no significant change in any HR parameter (time in five intensity zones from 50 to 100% of maximal HR). The blood ω3 fatty acid percentage (specifically, 20:5ω3, 22:5ω3, 22:6ω3, and total ω3) was higher in E compared to W and P, whereas the ω6 fatty acids percentage (specifically, 20:3ω6, 20:4ω6, 22:4ω6, and 22:5ω6) was lower in E compared to W and P ($p < 0.05$). As a result, the ω6/ω3 ratio was lower ($p < 0.05$) with E (7.74 ± 2.74) compared to W (9.50 ± 2.92) and P (9.84 ± 3.06).

CONCLUSION: Short-term HIFT increased training-session time independent of supplementation. Supplementation with E had positive effects on the blood fatty acids profile by increasing ω3 content, which may be beneficial for health and other training adaptations.

THE COLLAGEN SYNTHESIS RESPONSE TO LEG PRESS EXERCISE IN RESISTANCE-TRAINED MIDDLE-AGED MEN IS AUGMENTED WITH 15-30 G HYDROLYSED COLLAGEN SUPPLEMENTATION

NULTY, C.D.P.1,2, TANG, J.C.Y.3, DUTTON, J.D.3, DUNN, R.3, FRASER, W.D.3, ENRIGHT, K.1, STEWART, C.E.1, ERSKINE, R.M.1,6

1. LIVERPOOL JOHN MOORES UNIVERSITY; 2. SOUTH EAST TECHNOLOGICAL UNIVERSITY 3. UNIVERSITY OF EAST ANGLIA

INTRODUCTION: Nutrition and exercise prescription to support muscle-tendon unit (MTU) health and function in middle-age are often overlooked. Resistance training has, however, long been established as a potent stimulus to improve MTU function and reduce injury risk [1], and resistance exercise (RE) stimulates collagen synthesis in human muscle and tendon [2]. Recent data suggest that collagen supplementation may support exercise-driven adaptations of the MTU in young adults but the acute effects of RE combined with dietary collagen during middle-age remain unknown. We therefore hypothesised that collagen synthesis would increase in response to RE, and this effect would be augmented in a dose-dependent manner with hydrolysed collagen supplementation in middle-aged men.

METHODS: Nine resistance-trained men (age, 49±8 years; height, 178±2 cm; body mass, 90±4 kg), completed three trials in a double-blind, repeated measures crossover design. Each trial was conducted after an overnight fast. Participants consumed either 0g, 15g, or 30g vitamin C-enriched hydrolysed collagen in a randomised order 1-h prior to high-intensity leg-press RE. Venous blood samples were collected for the duration of each trial and assessed for a serum marker of type 1 collagen synthesis (N-terminal propeptide of type 1 pro-collagen, PINP), and plasma β-isomerized C-terminal telopeptide of type 1 collagen (β-CTx, a marker of collagen breakdown). The concentration × time total area under the curve (AUC) for serum PINP and plasma β-CTx were compared between trials.

RESULTS: There was a main effect of dose ($P=0.0018$) and a dose×time interaction ($P=0.0421$) for serum PINP concentration, with concentration in the 0g trial remaining similar to baseline (9.4±6.8 ng/mL) throughout the trial but increasing in both the 15 and 30g trials. PINP concentration×time AUC for the 15 and 30g trials were 122±60 and 141±70 ng/mL×h, respectively, which did not differ from each other ($P=0.314$) but were both higher than the 0g trial (74±45 ng/mL×h, $P=0.012$, $P=0.010$). β-CTx decreased by 30% after RE in all three trials and remained lower for the duration of each trial ($P<0.0001$), with no effect of dose ($P=0.940$) and no interaction ($P=0.899$). β-CTx AUC did not differ between trials (2.4±0.5, 2.6±0.7, 2.5±0.6 μg/L×h for 0g, 15g and 30g, respectively, $P=0.306$).

CONCLUSION: Ingestion of 15-30g hydrolysed collagen appears to augment collagen synthesis following RE in middle-aged, resistance-trained men without affecting collagen breakdown. This could be a viable strategy to improve MTU health and function over the long term in middle-aged individuals.

THE COLLAGEN SYNTHESIS RESPONSE TO HIGH-INTENSITY BACK SQUAT EXERCISE IN RESISTANCE-TRAINED YOUNG MEN IS GREATER WHEN INGESTING 30 G VERSUS 15 G HYDROLYSED COLLAGEN

LEE, J.1, TANG, J.C.Y.2,3, DUTTON, J.2, DUNN, R.2,3, FRASER, W.D.2,3, ENRIGHT, K.1, CLARK, D.R.4, STEWART, C.E.1, ERSKINE, R.M.1,5

1LIVERPOOL JOHN MOORES UNIVERSITY, UK; 2UNIVERSITY OF EAST ANGLIA, UK; 3NORFOLK AND NORWICH UNIVERSITY HOSPITAL NHS FOUNDATION TRUST, UK; 4ROBERT GORDON UNIVERSITY, UK; 5UNIVERSITY COLLEGE LONDON, UK.

INTRODUCTION: Jump-rope exercise with gelatine supplementation increases collagen synthesis in a dose-response manner, with 15g gelatine stimulating a greater response than 5 and 0g [1]. However, it is unknown whether >15g hydrolysed collagen (HC) supplementation would further increase collagen synthesis following resistance exercise (RE), which is known to increase collagen synthesis in muscle and tendon [2].

METHODS: Using a double-blind, randomised cross-over design, 10 resistance-trained male participants (age:26±3years; height:1.77±0.04m; mass:79.7±7.0kg; 4.0±3.3years of RE experience) ingested 0g, 15g or 30g HC with 50mg vitamin C, in a random order, prior to performing four sets' barbell back-squat at 10-repetition maximum load, after which they rested for six hours. Six venous blood samples were collected throughout each trial (at rest prior to HC ingestion (-1h) and post RE at +0.5h, +1h, +2h, +4h, and +6h) to analyse serum procollagen type I N-terminal propeptide (P I NP) concentration, a marker of collagen synthesis, and the concentration of amino acids comprising collagen. Plasma β-isomerized C-terminal telopeptide of type I collagen (β-CTX) concentration, a marker of collagen breakdown, was analysed at -1h and +6h.

RESULTS: The serum P I NP concentration×time area-under-the-curve was greater for 30g (267±79 ng·mL-1×hour) HC than 15g (235±70 ng·mL-1×hour, P=0.039) and 0g (219±88 ng·mL-1×hour, P=0.005) but there was no difference between 0g and 15g HC (P=0.675). Serum concentration of glycine, proline and hydroxyproline each showed a dose×time interaction (P<0.05) and a main effect of dose (P<0.05), with glycine and proline concentration higher in 30g than 15g HC (P<0.05). Plasma β-CTX concentration decreased from -1h (0.8±0.3 µg·L-1) to +6h (0.6±0.1 µg·L-1, P=0.007), with no effect of HC dose (P=0.287) or dose×time interaction (P=0.754).

CONCLUSION: These data suggest that, in resistance-trained young men, 30g HC augments collagen synthesis more than 15g and 0g HC following a single bout of high-intensity RE, whereas HC did not affect collagen breakdown. This has implications for improving physical performance, as augmented collagen synthesis may increase tendon stiffness [3], which is related to the rate of force development [4].

THE EFFECTS OF ACTOVEGIN AND HIIT ON BODY WEIGHT, BLOOD GLUCOSE AND LIVER MITOCHONDRIAL FUNCTION IN HEALTHY MICE

LINDTOFTE, S.1, HASSØ, R.1, KOSIK, B.2, BERGDAHL, A.2, LARSEN, S.1

1XLAB, DEPARTMENT OF BIOMEDICAL SCIENCES, FACULTY OF HEALTH SCIENCES, UNIVERSITY OF COPENHAGEN, DENMARK, 2DEPARTMENT OF HEALTH, KINESEOLOGY & APPLIED PHYSIOLOGY, CONCORDIA UNIVERSITY, MONTREAL, CANADA

INTRODUCTION: Actovegin (Act) has previously been shown to increase mitochondrial respiration acutely in human skeletal muscle[1] and in rat liver[2]. Act has also demonstrated insulin-like effects on glucose metabolism[3]. Likewise, physical activity has been shown to improve glycemic control[4] and liver mitochondrial function[5]. The aim of this on-going study is to investigate the effects of Act and aerobic exercise training on body weight, blood glucose and liver mitochondrial function in mice.

METHODS: A total of 40 healthy adult male mice were included in this study. The mice were divided into 4 groups; Act (A), controls (C), trained Act (AT) and trained controls (CT). All mice were treated for 14 days, with injections of either 0.1 ml Act (10mg/ml) or saline every other day. The training intervention consisted of a HIIT protocol, performed every other day by the trained groups (5 bouts of 1 min at 85-95 % of maximal running speed with 2 min active recovery at 60-65 % of maximal running speed between intervals). Body weight was measured every other day and blood glucose was measured on day 1, 7 and 14 of the intervention period. High resolution respirometry (Oroboros, O2K) was used to assess liver mitochondrial respiration after the intervention. Both state 2 (LEAK respiration) and state 3 (Maximal ADP stimulated respiration)

was assessed with the following protocol: 1mM Malate + 10mM Glutamate – 5µM Cytochrome C – 5mM ADP – 10mM Succinate – FCCP titration with steps of 0.25µM. One and Two-way ANOVA was used for the statistical analysis, with Tukey's multiple comparisons test post hoc with an alpha-level of 0.05.

RESULTS: All groups showed a loss of body weight ($p < 0.01$ for all groups) and drop in blood glucose ($p < 0.05$ for all groups) as a result of the intervention. Mitochondrial complex I LEAK respiration (State 2) was significantly lower in the CT group compared to both the C ($p < 0.05$) and A group ($p < 0.01$). No effects were found on mitochondrial respiratory capacity (State 3) or efficiency measured as RCR (State 3/State 2).

CONCLUSION: To our knowledge, this is the first study investigating the combined effects of Act and exercise training on liver mitochondrial respiration. Body weight and blood glucose declined uniformly in all groups, likely due to intervention induced stress rather than as an effect of Act or training. HIIT resulted in decreased LEAK respiration in the CT group, but overall Act and HIIT displayed limited effects on liver mitochondrial function, possibly due to the mice being fit and healthy. Act has been shown to affect mitochondrial function in skeletal muscle in healthy mice, suggesting Act may induce selective effects on different tissues.

OP-SH22 Stress-recovery and anxiety

LINK BETWEEN THE STRESS-RECOVERY BALANCE AND MINDFULNESS IN YOUNG ELITE BMX RIDERS

SONDT, N., BERNIER, M., KERMARREC, G., VACHER, P.

UNIVERSITÉ BRETAGNE OCCIDENTALE

Introduction

The stress-recovery balance refers to the quality of adjustment of recovery strategies that one mobilizes according to his or her stress states (Kellmann, 2010). Maintaining this balance plays an important part for the athletes and the coaches to reach an optimal performance. Currently, the scientific literature tries to develop the knowledge about psychological strategies of recovery among which, mindfulness has captured in interest (Blevins et al., 2021). From a biopsychosocial perspective, the aim of the study was to explore the links between mindfulness and the stress-recovery balance.

Method

24 young elite BMX riders from a National Training Center were followed-up during two weeks of intensive precompetition training. First, they completed the Mindfulness Inventory for Sport (MIS) and the Five Facets Mindfulness Questionnaire (FFMQ) to assess their mindfulness dispositions. The follow-up of the stress-recovery balance was made by psycho-physio measures: (1) they had to complete every morning the Short Recovery and Stress Scale (SRSS) and the Recovery Stress Questionnaire for Athletes (RESTQ) twice a week, and (2) heart rate variability was measured twice a week. After every training, riders rated their mindfulness states during training. By using the R package labeled lme4, multilevel growth curve analyses were used to examine the linear and/or quadratic trajectories of athletes stress-recovery variables and the scores of dispositional mindfulness and mindfulness states.

Results

Concerning mindfulness dispositions, results showed no significant effect with stress-recovery states, while a significant positive linear interaction effects of time on RMSSD (ß =7.67, . P < .05) was found. Regarding mindfulness states, results showed a significant negative linear interaction effects of time on stress (ß =- .25, . P < .05) and a significant positive quadratic interaction effect of time on recovery (ß = .38, . P < .001). No significant interaction effect with RMSSD was found.

Discussion

These results offer a better understanding of the links between mindfulness, as a disposition or a state, and stress-recovery balance. The study brings new applied and research perspectives. In particular, mindfulness could be considered as a recovery strategy. Future interventional studies should confirm its effects.

THE RELATION BETWEEN ATHLETES' NEGATIVE PERFORMANCE STRESS AND VIGOUR: A MODERATED MEDIATION ANALYSIS INCLUDING RUMINATION AND PSYCHOLOGICAL CAPITAL

BALK, Y.A., EHREN, M.

UNIVERSITY OF AMSTERDAM

Mentally disconnecting from sport is an important psychological recovery experience for athletes to cope with the demands of training and competition. Yet, those same sport-related demands can potentially interfere with athletes' ability to disconnect. Specifically, negative feedback, substandard performances, or mistakes could evoke ruminative thoughts, which likely impairs psychological recovery and might lead to impaired well-being. However, athletes' psychological capital (PsyCap) might help them to effectively deal with negative performance stress, thereby limiting its impact on rumination and subsequent well-being (i.e., vigour). The first aim of this study was to therefore investigate whether sport-related rumination mediates the relation between negative performance stress and vigour. The second aim was to examine whether athletes' psychological capital moderates the relation between 1) negative performance stress and rumination and 2) negative performance stress and vigour.

A total sample of 169 amateur athletes (n = 77), semi-professional athletes (n = 42) and professional athletes (n = 50) filled in an online survey (mean age = 22.62, SD = 5.18, 50% male, 50% female). Analyses using PROCESS showed a positive relation between negative performance stress and vigour (B = -.15, SE = .06, t(166) = -2.56, p = .011, 95% CI [-.27, -.03]). Negative performance stress was positively related to rumination (B = .44, SE = .06, t(166) = 7.34, p < .001, 95% CI [.32, .56]). Furthermore, rumination was negatively related to vigour (B = -.16, SE = .08, t(166) = -2.12, p = .035, 95%CI [- .31, -.01]). Results also revealed a significant indirect effect of rumination between negative performance stress and vigour (B = -.07, 95% CI [- .150, -.002]). As the direct effect of negative performance stress on vigour became was not significant (B = -.08, p = .231, 95% CI [-.21, .05]), rumination fully mediated the relation between negative performance stress and vigour. Finally, psychological capital was negatively associated with rumination (B = -.28, SE = .13, t(166) = -2.24, p = .026, 95% CI [-.52, -.03]) and positively associated with vigour (B = .53, SE = .12, t(166) = 4.53, p < .001, 95% CI [.30, .77]). However, psychological capital did not moderate the relations between negative performance stress and rumination or vigour (p's > .17). Thus, the mediated moderation model was not supported.

Taken together, these findings show that negative performance stress experienced by athletes is negatively associated with vigour, through increased rumination about their sport. PsyCap did not attenuate these relations, although it appears to benefit athletes' general levels of rumination and well-being. Coaches and sport psychologists should be aware of how athletes cope with negative performance stress and assist them in reducing ruminative thoughts to optimize psychological recovery processes and well-being.

THE IMPACT OF COACHING ON ATHLETES' COPING AND AFFECTIVE STATES EXPERIENCED IN COMPETITIVE SETTINGS

GONZÁLEZ-GARCÍA, H., MARTINENT, G., NICOLAS, M.

*UNIVERSIDAD INTERNACIONAL DE LA RIOJA *; UNIVERSITÉ CLAUDE BERNARD LYON 1 **; UNIVERSITÉ BOURGOGNE FRANCHE-COMTÉ ****

Introduction

Coaching practices have revealed a salient impact on athletes coping and affective experience in sports. Consequently, there is an increasing necessity to examine how coaching practices may influence coping and the affective experience in the competition, especially due to the link of the mentioned variables with sports performance. As such, the present work will be divided into two distinct studies that address coaching from two different theoretical backgrounds. In study 1, the goal was to examine whether the coach athlete-relationship predicted: "coping" and "intensity and direction of positive affects and negative affects" experienced before and during competition. In study 2, it was aimed to examine whether coach leadership behaviours predicted: the intensity and direction of positive and negative affects experienced during competition, controlling for affects experienced within two hours before competition.

Methods

Two samples of 306 and 296 French athletes participated in two distinct studies and completed a series of self-report questionnaires. In both studies, a partial least square path modelling (PLS-PM) approach was used to examine the relationships between the variables.

Results

Study 1: The analysis revealed that coach-athlete commitment positively predicted task-oriented coping before the competition, disengagement-oriented coping before the competition, distraction oriented-coping before the competition, and negatively predicted the direction of negative affects during competition. Besides, the coach-athlete complementarity negatively predicted disengagement-oriented coping before the competition, positively predicted intensity of positive affects before the competition and marginally positively predicted intensity of negative affects during the competition.

Study 2: The results showed that coach social support significantly positively predicted the direction of negative affects during competition controlling for pre-competitive negative affect direction. Besides, results revealed that coach democratic behaviour marginally and negatively predicted Negative Affects direction during competition whereas coach autocratic behaviour marginally and negatively predicted Positive Affects intensity.

Conclusion

These outcomes should take the attention of practitioners to emphasize positive social support interrelation between coach and athlete as well as do not emphasize excessive commitment in coaches, especially in the precompetitive parts of the competition.

DO ATHLETES RESIST BETTER TO FAILURE WHEN THE "I" OR THE "WE" MATTERS MOST? THE IMPORTANCE OF THE FAILLURE TYPE

PELLET, J., LAURIN, R., CAMPO, M.

UNIVERSITY OF BURGUNDY

Introduction

Literature reported studies exploring individual collapsing through the scope of self-image threat (Mesagno & Beckmann, 2017). However, in team-based sports, individual collapsing may be conceptualized as an affective approach/avoidance response, and may be influenced by group identification, and the collective stakes associated with it (Haslam et al., 2020).

To our knowledge, no model investigated the influence of identity processes on players' withdrawal during competition. Accordingly, we propose to investigate this effect by considering a perception of an individual or collective failure context

Method

Student in sport sciences (N=149) were divided into a 2x2 design manipulating identity levels (social SI vs individual PI) and failure type (personal vs collective failure). Participants had to perform a speed-accuracy task of basket-ball throwing aiming at targets. Procedure involved (a) a training task, (b) a stake induction, (c) an identity manipulation, and (d) the main task with a failure manipulation. Participants did not have access to their performance, allowing us to always give them rigged feedbacks of faillure. Following each feedback, participants had to make the choice to continue or stop.

Results

The dependent variable is the number of repetitions performed. A factorial ANOVA revealed an interaction effect between the type of failure and the identity level. Post-hoc tests revealed a significant difference between PI and SI in the collective failure scenario. A tendential difference between PI and SI in the individual failure scenario was also revealed. This means a greater tendency for participants to withdraw when they considered themselves as group member in a collective faillure scenario, and when they considered themselves as individual in an individual faillure scenario.

Discussion

Failure seems to be threatening only when it concerns the athlete salient identity level, therefore triggering avoidance processes and behaviors. As failure is not something socially valued in an achievement context, these results are consistent with the self-esteem preservation hypothesis proposed by Tajfel and Turner, echoing current knowledge on perception of an identity threat provokes negative emotions that may lead to avoidance behaviours (Hunger et al., 2015).

IS-PN02 Exercise and nutrition to support healthy aging

SARCOPENIA: CAUSES, CONSEQUENCES, AND TREATMENT OPTIONS

VERDIJK, L.

MAASTRICHT UNIVERSITY MEDICAL CENTRE

Sarcopenia is defined as the progressive loss of muscle mass and function with increasing age. Whether a direct consequence of aging per se, or more indirectly associated with age-related disease, sarcopenia goes hand in hand with a number of physical and metabolic derangements, underscoring the need for effective countermeasures. Muscle mass maintenance is determined by the intricate balance between muscle protein synthesis and muscle protein breakdown rates. It has been well established that physical activity and food intake (primarily protein intake) represent the two main anabolic stimuli affecting this balance and, as such, play an essential role in muscle maintenance throughout life. Though the etiology of sarcopenia is likely multifactorial, recent work suggests that a diminished response to protein intake and

physical activity in elderly versus young individuals may be a key factor driving the loss of skeletal muscle tissue throughout the aging process. This phenomenon has been termed □anabolic resistance□. Such anabolic resistance is even more profound in certain disease conditions and during periods of physical inactivity such as during hospitalization, further accelerating the loss of muscle mass and function in those situations.

In this lecture, an overview will be given on the causes, consequences and treatment options for sarcopenia, with a focus on exercise and nutrition to improve muscle mass and function and support overall health in the aging population. Apart from presenting current knowledge, we will also identify challenges that should be addressed in future research.

SARCOPENIC OBESITY

BOIRIE, Y.

CLERMONT-FERRAND UNIVERSITY HOSPITAL

Apart from the age-related decline in muscle mass and function, many older individuals struggle to maintain body weight within healthy limits, resulting in a high prevalence of overweight and obesity. Importantly, the presence of excess body fat (along with e.g. associated insulin resistance and inflammation) has multiple negative effects on muscle tissue, and may further enhance the anabolic resistance already present in senescent muscle. As such, age-related functional and metabolic deteriorations are further enhanced with so-called 'sarcopenic obesity'. Sarcopenic obesity is a new clinical entity that also raises new clinical and scientific questions. It leads us to rethink the management of sarcopenia where excessive adiposity and muscle deficit can coexist. In particular, the role of ectopic muscle adiposity or more directly of lipotoxicity on muscle signaling pathways is a promising area of research, particularly in the context of chronic diseases in order to preserve the mobility and quality of life of patients. This lecture will describe the etiology of sarcopenic obesity, and the targeted approach needed to better preserve muscle mass and function in this chronic disease situation.

RESISTANCE TRAINING AND PROTEIN INTAKE IN OLDER PEOPLE: HOW TO BRING SCIENCE TO PRACTICE?

DE GROOT, L.

WAGENINGEN UNIVERSITY

Clinical studies show that sufficient protein intake combined with resistance exercise can maintain or improve muscle health and function in older adults. Based on this concept, an innovative and evidence-based lifestyle program for vulnerable older people was developed and daily implementation of the program was evaluated in terms of cost-effectiveness to improve independency as well as quality of life of the elderly. This lecture will describe the outcomes of this 'ProMuscle in Practice' project which consisted of three phases. In phase one, an effective clinical trial was adapted to fit the real-life practice setting using input from health care professionals, the target group (elderly people) and researchers. This resulted in protocols that can be used by physiotherapists and dieticians to implement this program. In the second phase, a pilot implementation project was performed in which community-dwelling elderly received progressive resistance exercise in small groups, guided by physiotherapists, as well as advice on how to increase their daily protein intake by dieticians. Finally, a large-scale multi-centre intervention study was conducted to investigate the implementation process and (cost-) effectiveness of 'ProMuscle in Practice' in 5 different care and community settings. As such, the project is exemplary for translation of science into practice, establishing whether the adapted program is effective in supporting healthy aging in the community.

OP-PN14 Oxygenation

ACUTE MUSCLE OXYGEN SATURATION AND PERCEPTUAL RESPONSES BETWEEN LUNGE AND RUNNING EXERCISES VARIATIONS

SANTARÉM, D.1, TEIXEIRA, A.1, AMARAL, A.1, SAMPAIO, J.1,2, MACHADO, I.1,2, ABRANTES, C.1,2

1. UNIVERSITY OF TRÁS-OS-MONTES E ALTO DOURO , VILA REAL, PORTUGAL; 2. RESEARCH CENTER IN SPORTS SCIENCES, HEALTH SCIENCES AND HUMAN DEVELOPMENT , UTAD, VILA REAL, PORTUGAL.

INTRODUCTION: Over the past decades there has been an exponential increase in the use of high-precision devices to monitor training, assuming itself as an unquestionable factor for the success of athletes (1). Near-infrared spectroscopy (NIRS) is considered a non-invasive viable way to analyse the kinetics of muscle oxygen saturation (SmO2), both at rest and during exercise (2), allowing a more specific observation of the physiological response to exercise. This study aimed to compare the effect of six variations of lunge (LUN) and running (RUN) exercises in SmO2, heart rate (HR), and perceived exertion (RPE).

METHODS: Were recruited 16 participants and divided into two exercise groups: the LUN (n=8; age=26.3±3.8 yrs) comprised isometric, jumping, walking, cross, bulgarian, and side terra-core lunge exercise variations, and the RUN (n=8; age=34.5±12.0 yrs) comprised high-knees, shoulder wide, tethered, treadmill (0%), slope treadmill (6%), and shoulder-wide coreboard run exercise variations. Each variation lasted 90s with a 5-min rest interval between each one. Average and minimum SmO2 (SmO2avg and SmO2min, respectively) of vastus lateralis (VL) and gastrocnemius medialis (GM)

muscles, and average HR (HRavg) were assessed through the session, and RPE immediately after each variation. A one-way ANOVA (or Kruskal-Wallis) and Tukey's post-hoc were used to find differences among the studied exercise variations.

RESULTS: Significant differences were found between exercises variations in HRavg, F(11,84)=2.86, p=0.003, n2=0.27, with higher values in jumping LUN vs coreboard RUN (145.8±18.8 vs 116.3±14.5 bpm, p=0.027), and in high-knees RUN (146.3±12.1 bpm) vs isometric lunge LUN (117.7±23.0 bpm, p=0.038). Significant differences in SmO2avg in GM muscle were identified, F(11,72)=17.71, p<0.001, n2=0.73, with almost all variations of LUN showing higher values vs RUN, except for coreboard RUN variation. The SmO2min in GM muscle showed significant differences, F(11,66)=15.38, p<0.001, n2=0.72, with RUN variations presenting lower values relative to LUN variations, except in coreboard RUN vs jumping lunge LUN (p=0.188). The overall and muscular RPE exhibited higher values in RUN compared to LUN variations.

CONCLUSION: The findings revealed that in general RUN exercises promoted higher HRavg and lower SmO2, except for coreboard RUN exercise when compared to jumping LUN. These two exercises were selected due to their applicability in the training context, making it possible to better understand both general and specific physiological responses combining HR with SmO2 and RPE.

A DIVE INTO THE PHYSIOLOGY OF O2 AND CO2 TABLES IN APNEA NOVICES

DECLERCQ, L.1, BOUTEN, J.1, HEYSE, B.2, BOONE, J.1, BOURGOIS, J.G.1,3

GHENT UNIVERSITY

INTRODUCTION: During apnea, bradycardia and peripheral vasoconstriction characterize the cardiovascular diving response aimed to protect the brain from oxygen deprivation. The diving response has already been studied intensively during maximal apneas, but information on training protocols of submaximal apneas is lacking. O2 and CO2 tables are timed repeated submaximal breath-holds used by free divers to improve apnea duration. The aim of this study was to describe the physiological responses during maximal apneas, O2 and CO2 tables in order to determine the most feasible training method to improve apnea duration in apnea novices.

METHODS: 28 physically active individuals (23 ± 3 years old; 175 ± 9 cm; 69.7 ± 7.9 kg) naïve to apnea performed 3 apnea protocols in random order: traditional based training session (maximal apneas), O2 table (increasing apneic time, long rest periods), CO2 table (short apneas, decreasing rest periods). Heart rate (HR), muscle and cerebral oxygenation (by NIRS) and arterial oxygen saturation (SaO2) were measured continuously during apnea. RM ANOVA's were used to compare acute changes between protocols throughout the final apnea for ΔHR, peripheral (ΔmTOI) and cerebral (ΔcTOI) tissue oxygenation index and ΔSaO2.

RESULTS: Decrease in ΔHR and ΔmTOI did not significantly differ between protocols (p=0.662; p=0.545). ΔcTOI remained close to baseline at the end of the final apnea in CO2 tables (-1 ± 9%), while a significant drop was seen in O2 tables (-6 ± 10%) and the maximal apnea protocol (-14 ± 15%) (p=0.012). ΔSaO2 decreased significantly more during maximal apneas (-15 ± 4%) compared to O2 tables (-5 ± 2%) and CO2 tables (-4 ± 2%) (p=0.004).

CONCLUSION: Despite a similar cardiovascular diving response in the three protocols, arterial oxygen saturation and brain oxygenation decreased to a greater extend during the maximal apnea protocol. Compared to the maximal apnea protocol, O2 and CO2 tables provide less physiological strain on the body. A combination of all three protocols seems most feasible to improve apnea duration in apnea novices.

POST-ISCHEMIA MICROVASCULAR REACTIVITY DURING ACUTE HYPOXIC EXPOSURE IN TRAINED AND UNTRAINED MALES AND FEMALES

MANFERDELLI, G.1, RABERIN, A.1, SCHORDERET, F.1, MILLET, G.P.1

1: UNIVERSITY OF LAUSANNE

INTRODUCTION: Sex-specific differences in vascular function have been widely investigated but contrasting findings have been reported. Recent evidence showed greater skeletal muscle resting oxidative metabolism in trained males and females compared to their untrained peers, as well as in males compared to females. Hypoxia is also known to affect skeletal muscle environment by inducing local vasodilation, but the combined influence of sex, fitness level and acute hypoxic exposure on microvascular reactivity remains unclear. Preliminary results suggest that, under hypoxic conditions, females have lower peripheral limitations during exercise compared to males. This study investigated sex and fitness level differences in acute microvascular responses to ischemia and compared endurance trained vs untrained, female vs male young adults in normoxia vs normobaric hypoxia.

METHODS: Fifty young healthy participants were divided in four groups according to their sex and aerobic fitness; trained females (TF, n=12, VO2peak=54.9±4.0 ml·min-1·kg-1), control females (CF, n=11, 46.3±3.8 ml·min-1·kg-1), trained males (TM, n=12, 68.0±6.8 ml·min-1·kg-1) and control males (CM, n=15, 54.3±4.3 ml·min-1·kg-1). Participants performed two incremental cycling tests to exhaustion, one in normoxia and the other in normobaric hypoxia (FIO2=0.141), to determine peak oxygen uptake (by metabolic cart). Before each test, resting skeletal muscle oxidative metabolism and post-ischemia

microvascular responsiveness in normoxia and hypoxia were evaluated by combining Near-Infrared Spectroscopy and the vascular occlusion test on the vastus lateralis muscle.

RESULTS: Hypoxia lowered VO2peak in all participants (P<0.001), though the magnitude of the decrease was greater in males compared to females (P<0.001) and in trained compared to untrained (P<0.001). Baseline tissue saturation index (TSI) was lower in males compared to females (P<0.001), in trained compared to untrained participants (P=0.011), and in hypoxia compared to normoxia (P=0.010). The desaturation rate (calculated as the linear regression during the first 60-secs of occlusion) and the reperfusion rate (calculated as the linear regression of the first 10-secs post-occlusion) were lower in females compared to males (P<0.001 and P<0.001, respectively) and in hypoxia compared to normoxia (P<0.001 and P=0.048). When the reperfusion rate was normalized for the ischemic stimulus (i.e., minimum TSI reached during the 5-min occlusion), females showed a lower reperfusion rate compared to males (P<0.011), with no effects of fitness level or hypoxia.

CONCLUSION: In conclusion, young female adults demonstrated reduced resting skeletal muscle oxidative metabolism and microvascular responsiveness compared to males, but without differences between fitness levels nor influence of hypoxic exposure.

MUSCLE OXYGENATION UNDULATES DURING EACH REPETITION OF RESISTANCE EXERCISE

MAVRIDIS, K., PETRIDOU, A., MOUGIOS, V.

ARISTOTLE UNIVERSITY OF THESSALONIKI

INTRODUCTION: Although near-infrared spectroscopy (NIRS) has been widely used in studying muscle oxygenation in endurance exercise, its use in resistance exercise is limited (Miranda-Fuentes et al., 2021). Muscle oxygenation during resistance exercise depends on intensity, volume, rest interval between sets, duration of each repetition, type of muscle activity, and muscle being evaluated. Data separating the eccentric and concentric phases of dynamic resistance exercise are lacking. Thus, the aim of this study was to examine the oxygenation of three quadriceps muscles [vastus lateralis (VL), vastus medialis (VM) and rectus femoris (RF)] during the eccentric and concentric phases of the parallel high-bar back squat.

METHODS: Eighteen young resistance-trained males performed 5 sets of parallel high-bar back squat in a Smith machine, with 15 repetitions each: two warm-up sets [at 14% and 45% of 15-repetition-maximum (15RM)] and 3 main sets at 100% 15RM. Participants exercised while watching a model video, so that the duration of the descending (eccentric) and ascending (concentric) phases be exactly 1.5 s each. Rest interval between sets was 2 min. Three NIRS devices were attached to VL, VM and RF of the dominant leg and recorded muscle oxygen saturation (SmO2) at a frequency of 2 Hz, thus producing three values per phase. Blood lactate concentration was measured after each set. Data are presented as mean ± SD. SmO2 data were analyzed by repeated-measure two-way ANOVA (muscle x set), and lactate data were analyzed by one-way ANOVA.

RESULTS: In all three muscles, SmO2 dropped during each set and was reinstated during recovery. The drop from start to end of each set differed between muscles (65.5 ± 7.0, 63.2 ± 8.0% and 36.2 ± 21.2 for VL, VM and RF, respectively, $p < 0.001$) and sets (in sequence, 34.8 ± 13.8, 53.5 ± 10.1, 59.8 ± 8.6, 64.6 ± 9.0 and 64.8 ± 8.0%, $p < 0.001$). Importantly, SmO2 undulated during each repetition, increasing during the descending phase and decreasing during the ascending phase. The average amplitude of SmO2 undulation was 4% in VL, 10% in VM and 8% in RF, reaching at times two-thirds of the average SmO2. The half-time of muscle reoxygenation was 28 ± 8 s after each set. Blood lactate increased linear from set to set ($p < 0.001$), reaching 9.9 ± 3.9 mmol/L at the end.

CONCLUSION: Quadriceps muscle oxygen was largely depleted and rapidly repleted during exhausting squatting exercise. This, combined with the modest lactate values, suggests a high aerobic energy contribution. For the first time, we report that SmO2 undulated during each repetition in a way corresponding to the magnitude of the instantaneous energy demands, that is, increasing while lowering the weight and decreasing while lifting the weight. This indicates a quick response of the circulatory system in providing as much oxygen as possible to the exercising muscles.

THE INFLUENCE OF SEX ON PULMONARY OXYGEN UPTAKE AND DEOXYHEMOGLOBIN KINETICS DURING MODERATE AND SUPRAMAXIMAL INTENSITY RUNNING

CURTO, D.1,2, NICOLAU, M.1, ESPADA, M.3, MONTEIRO, C.1,2, MATIAS, C.4, MORGADO, J.4, ALVES, F.1,2, REIS, 1,2,5

1- FACULDADE DE MOTRICIDADE HUMANA, UNIVERSIDADE DE LISBOA, PORTUGAL; 2- CIPER, FMH, UL, PORTUGAL 3- IPS, SETUBAL, PORTUGAL 4- CIDEFE, LISBOA PORTUGAL 5- LQRC-CIEQV, RIO MAIOR, PORTUGAL

INTRODUCTION: Women have smaller hearts, cardiac outputs, hemoglobin concentrations (1) and higher O2 extraction for the same relative exercise intensity than men while presenting a less effective matching of the O2 delivery and utilization (2). These sex differences in the ability to deliver and to use oxygen by the working muscle could potentially influence pulmonary oxygen uptake (VO2) and deoxyhemoglobin ([HHb]) kinetics at different exercise intensities. However, research has produced conflicting results with studies showing faster VO2 kinetics in males whereas other found no differences. Also, the literature that simultaneously evaluated VO2 and [HHb] kinetics are scarce. Therefore, we aimed to compare the

VO2 and [HHb] kinetics at moderate and supramaximal intensity running between physically active adult men (M) and women (W).

METHODS: Twenty seven participants (14 M; 27.43 ± 5.69 years; 71.95 ± 7.56 kg and 13 W; 22.85 ± 4.22 years; 56.25 ± 5.97 kg) completed one incremental test to exhaustion to determine VO2max, first ventilatory threshold (VT1), second ventilatory threshold (VT2) and maximal aerobic velocity (MAV), and square wave transitions for moderate (80% of VT1) and supramaximal (110% of MAV) intensities. VO2 was collected breath-by-breath and [HHb] of the vastus lateralis was determined by near-infrared spectroscopy. The parameters of the VO2k and [HHb] kinetics were determined using a monoexponential model. Data was compared between sexes by an independent samples T Test, with significance level set at < 0.05.

RESULTS: No significant differences were observed between groups, in the time constant of the primary component of the VO2 and HHb kinetics neither for moderate (M: 30.75 ± 8.54 s; W: 31.52 ± 6.71 s and M: 19.39 ± 7.02 s; W: 24.73 ± 18.76 s, respectively) nor supramaximal running (M: 23.51 ± 10.19 s; W: 19.56 ± 6.73 s and W: 17.73 ± 9.81 s; F: 18.02 ± 16.97 s, respectively). However, men presented higher VO2 kinetics amplitude in supramaximal exercise than women (M: 44.69 ± 7.97 ml.kg-1.min-1; W: 39.25 ± 4.03 ml.kg-1.min-1). Men also had higher body mass (M: 71.95 ± 7.56 kg; W: 56.25 ± 5.97 kg) , and velocity associated with VT1, VT2, and MAV (M: 8.93 ± 1.07 km.h-1; W: 7.62 ± 0.87 km.h-1; M:11.62 ± 1.04 km.h-1; W: 10.31 ± 0.95 km.h-1; M: 14.82 ± 1.23 km.h-1; W: 12.96 ± 1.03 km.h-1, respectively).

CONCLUSION: Although men presented higher velocities associated with traditional endurance parameters, namely ventilatory thresholds and MAV, the time constant for VO2 and [HHb] kinetics were not different between sexes in moderate and supramaximal intensities. On the other hand, we observed higher amplitudes in men at supramaximal intensities suggesting a higher rate of increase of oxygen uptake per second in men and consequently a quicker onset at higher exercise intensities. ECCENTRIC HAMSTRINGS TORQUE PRODUCTION AND ELECTROMYOGRAPHIC ACTIVITY OF THE POSTERIOR MUSCLE CHAIN DURING UNASSISTED VERSUS ASSISTED NORDIC HAMSTRING EXERCISE

DEMEUSOY, P., CORCELLE, B., MARCHAND, F., BAIZE, D., BONTEMPS, B., DA SILVA, F., MONJO, F., PIPONNIER, E.
UNIVERSITÉ CÔTE DAZUR

INTRODUCTION: The deficit of maximal hamstrings eccentric torque is considered as a major risk factor of hamstring strain injury (1). As a result, many eccentric exercises have been developed, with the Nordic Hamstring Exercise (NHE) being among the most effective in improving eccentric torque and prevent muscle injuries. However, some athletes are not able to withstand the load imposed by this exercise. Assisted NHE has recently been investigated to enhance hamstrings strength at long muscle length (2). However, it remains unknown whether assisted NHE would result in greater eccentric torque production and/or activities of posterior muscle chain than classical NHE, i.e. unassisted NHE. In this line, our study was designed to compare hamstrings eccentric torque production and electromyographic (EMG) activities of the posterior muscle chain during unassisted NHE and four different assisted NHEs.

METHODS: Twelve voluntary participants (9 males, 3 females, age: 24.6 ± 4.5 years) performed five different NHE at maximal eccentric intensity and at the same controlled knee angular velocity. One was the classical unassisted NHE. Two assisted NHEs were performed to replicate the unassisted NHE (constant hip flexion of 0°), bilaterally and unilaterally (NHE0B and NHE0U, respectively). The two other assisted NHEs were performed unilaterally and reproduced the most common hamstring strain injury mechanisms. The first one reproduced the over-stretch mechanism, with constant 90° of hip flexion during the movement (NHE90U), and the second one reproduced the sprint-related hamstring strain mechanism, with knee and hip kinematics based on the late swing phase of the sprint step cycle (NHELSU). Maximal hamstrings eccentric torque production (Tmax), time-torque integral (TTi) and EMG integral (iEMG) of seven muscles of the posterior muscle chain were calculated during each NHE.

RESULTS: Unassisted NHE resulted in significantly lower Tmax ($p<0.05$) and TTi ($p<0.001$) than all assisted NHEs, as well as a lower iEMG in majority of measured muscles ($p<0.05$). In addition, for injury specific assisted NHEs, only NHELSU showed a significantly greater Tmax ($p<0.01$) than during NHE0U. However, no significant difference was reported in hamstrings iEMG between NHELSU and NHE0U.

CONCLUSION: Assisted NHE results in a greater time under tension and muscle length of hamstrings at the end of the movement. This could explain the greater eccentric torque production and higher integrated EMG activities of posterior muscle chain during assisted NHEs. In addition, eccentric torque could be maximized during NHELSU due to the continuous shift in hip flexion. To maximize hamstrings eccentric torque and activation, our results suggest that assisted NHE should be preferred over unassisted NHE. Assisted NHE replicating the sprint-related hamstring strain mechanism could be considered as the preferred modality for hamstring eccentric training or hamstring strain injury prevention.

THE ACUTE EFFECTS OF TRANSCRANIAL DIRECT CURRENT STIMULATION ON THE PERFORMANCE OF VELOCITY-BASED SQUAT TRAINING

CHEN, T., ROMERO-ARENAS, S.

UNIVERSIDAD CATÓLICA SAN ANTONIO

INTRODUCTION: Transcranial direct current stimulation (tDCS) was found to increase the number of repetitions, maintain movement velocity, and lower perceived exertion while performing strength training until exhaustion (1). Before reaching a defined velocity loss, tDCS may enhance the number of repetitions with a lower perceived effort. Hence, tDCS may modulate the performance of velocity-based training. Therefore, the aim of this study was to examine the effects of tDCS on the number of repetitions, movement velocity, and rating of perceived exertion (RPE) in squat exercise when the velocity loss is less than 15%.

METHODS: Eight healthy men (age 22 ± 3.4 years) were subjected to 20 min of 2.0 mA anodal tDCS over either [1] the bilateral primary motor cortex (M1) or [2] the dorsolateral prefrontal cortex (DLPFC), or 20 min of [3] a SHAM stimulus in a crossover randomized controlled trial manner. The direct current was imposed on a pair of square electrode pads (7.6cm × 7.6cm). Immediately after each stimulus, the first set of repeated explosive (only in the concentric phase) squats was performed until a 15% decrease in the mean propulsive velocities (MPV); the number of repetitions and MPV were assessed, and the RPEs before and after each repeated squats were recorded in OMNI-RES scale. After 90 s, the following four consecutive sets were conducted in the same manner with 90 s intervals. The data were compared by repeated measures ANOVA.

RESULTS: Immediately after the stimuli over M1 and DLPFC, the number of repetitions (8.4±2.5 and 8.3±3.3, respectively) was higher than those after a SHAM stimulus (6.6±3.2; p= 0.25 and 0.29 against M1 and DLPFC, respectively). After 90 s interval, the number of repetitions decreased to 7.0±2.6 (for M1, p=0.04 vs. SHAM), 6.5±2.6 (for DLPFC, p= 0.1 vs. SHAM), and 4.6±1.1 (for sham). After the first two training sets and intervals, the effects of tDCS on the number of repetitions were not apparent (the 3rd set: 6.0±1.9 for M1, 5.6±2.4 for DLPFC, 5.8±1.7 for sham). For the MPV, the M1 stimulus resulted in a persistently higher velocity (0.61±0.05 m/s, p=0.25 vs. SHAM) than the DLPFC (0.59±0.04 m/s, p=0.69 vs. SHAM) and sham (0.58±0.05 m/s) for all five sets. The RPEs for all three stimuli increased from four (the first set) to eight (the fifth set) in a similar manner.

CONCLUSION: The tDCS induced an enhancing effect on the MPV of the explosive concentric phase of squats, and the improved performance in the number of repetitions (especially in the first two sets) could be conducted with similar RPEs. Therefore, the ergogenic effect of tDCS on explosive exercise is not only perceptual, it did exert realistic positive influences on physical performance.

EVIDENCE FOR HUMAN MUSCLE MASS REALLOCATION IN RESPONSE TO RESISTANCE TRAINING

VAN VOSSEL, K.1, HARDEEL, J.1, VAN DE CASTEELE, F.1, VAN DER STEDE, T.1,2, BOONE, J.1, BLEMKER, S.3,4, LIEVENS, E.1, DERAVE, W.1

1. GHENT UNIVERSITY; 2. UNIVERSITY OF COPENHAGEN; 3. UNIVERSITY OF VIRGINIA; 4. SPRINGBOK ANALYTICS

INTRODUCTION: Human skeletal muscle has the profound ability to hypertrophy in response to resistance training. Yet, muscle mass accretion has a high energy and protein cost (1) and is mainly restricted to recruited muscles. To date, it remains largely unknown what happens with non-recruited muscles during chronic resistance training, especially in relation to dietary energy and protein availability. Using advanced MRI- and AI-based approaches for muscle segmentation, we investigated the volume changes of upper arm muscles and all leg muscles, both those recruited and non-recruited, during a single-joint resistance training program.

METHODS: Eleven male and 10 female young, resistance training novices performed 10 weeks of knee extensions, knee flexions, arm extensions and arm flexions to failure 3x/week. Volume changes of the recruited (n = 17) and non-recruited (n = 13) upper arm and leg muscles were measured by MRI-based 3D segmentation. Daily energy (kcal/kg fat free mass) and protein (g/kg body mass) intake were measured thrice by self-reported diaries. Subjects were post-hoc divided into a HIGH (n = 11) or LOW (n = 10) energy intake group. Training-induced volume changes (paired sample t-tests) and differences between the HIGH/LOW energy intake groups (ANCOVAs, sex as covariate) were assessed. Pearson correlations examined relationships between energy/protein intake and volume changes.

RESULTS: The training program induced significant hypertrophy in all recruited arm and leg muscles (range: +2 to +17%). In contrast, the non-recruited adductor magnus (-1.5 ± 3.1%, p = 0.04) and soleus (-2.4 ± 2.3%, p <0.001) significantly decreased in size. Positive correlations were found between energy intake and changes in adductor magnus (r = 0.61, p <0.01) and soleus volume (r = 0.43, p = 0.05) and between protein intake and changes in adductor magnus (r = 0.45, p = 0.04), gastrocnemius medial head (r = 0.43, p = 0.05) and tibialis posterior volume (r = 0.43, p = 0.05). The LOW energy intake group showed atrophy in the adductor longus (-4.7 ± 4.0%, p <0.01), soleus (-3.4 ± 2.0%, p <0.01), adductor magnus (-2.9 ± 2.3%, p <0.01) and fibulari (-2.2 ± 2.6%, p = 0.04) while no volume loss was observed in any individual muscle of the HIGH energy intake group.

CONCLUSION: To our knowledge, this is the first study to document the basic but surprising finding that some non-trained muscles significantly atrophy in a period of resistance training. Our data therefore suggest muscle mass reallocation, i.e. that muscle hypertrophy in recruited muscles takes place at the expense of muscle atrophy in non-recruited muscles, especially when energy and/or protein availability is limited. This could be important to understand the evolutionary advantage of maintaining the hypertrophy potential in states of low energy availability (e.g. famine) and could have modern-day applications for sport science (e.g. training while weight cutting) and health-related resistance training.

DOES THE TRAINING BREAK MATTER? UPPER AND LOWER LIMB MUSCLE STRENGTH FOLLOWING 20-WEEK INTERMITTED VS. CONTINUOUS RESISTANCE TRAINING

AHTIAINEN, J.P., HALONEN, E., HULMI, J.J.

FACULTY OF SPORT AND HEALTH SCIENCES, UNIVERSITY OF JYVÄSKYLÄ

INTRODUCTION: In everyday life, people face challenges implementing systematic resistance training (RT). Health problems, work commitments, etc., can prevent RT for a period, which can compromise achieving the benefits of regular RT. This study aimed to examine the effect of a detraining period in the middle of the RT intervention on maximal upper and lower limb strength response.

METHODS: 42 healthy, previously untrained men and women volunteers (32 (5) years) participated in a 32-week intervention. Participants were randomized (stratified by sex, age, and BMI) into intermitted (TraDeRe, n=20) and continuous training groups (ConTra, n=22). TraDeRe group conducted a 10-week RT period followed by a 10-week detraining period. After that, a 10-week RT was repeated like the first period. ConTra started with a 10-week non-training period followed by a 20-week RT. The RT protocol was the same for both groups, with equal volume load for the elbow flexors and knee extensors. The supervised RT was carried out twice per week, and the program included 3x10 bench presses and 4 sets of 10 repetitions of leg presses, knee extensions, biceps curls, and seated back row. The last set of the training week was continued until failure, and the RT loads for the following week were determined accordingly. One repetition maximum (1RM) of barbell biceps curl (BC) and horizontal concentric leg press (LP) was tested 2 weeks before the intervention, before the first study period (Pre), and after each study period.

RESULTS: Technical error of measurement was 5.4% and 8.7% between -2 and 0 weeks in LP and BC, respectively. LP increased ($p < 0.001$) by 22 (9) % and 29 (11) % in ConTra and 22 (13) % and 29 (16) % in TraDeRe after the first and second 10-week RT period, respectively. BC increased ($p < 0.001$) by 22 (11) % and 34 (15) % in ConTra and 25 (19) % and 35 (21) % in TraDeRe after the first and second 10-week RT period, respectively. No statistically significant differences were observed between the groups. Detraining induced a -5 (4) % ($p < 0.001$) and -4 (7) % ($p < 0.05$) decrease in LP and BC, respectively. The gains in LP and BC did not correlate after the intervention ($r = 0.272$, $p = 0.083$). In TraDeRe, gains in the first and second 10-week RT period correlated in LP ($r = 0.720$, $p < 0.001$) but not in BC ($r = 0.360$, $p < 0.119$).

CONCLUSION: A 10-week detraining period between two 10-week RT periods did not compromise the improvement in maximal strength compared to continuous RT. Thus, at least during the first few months of RT, a 10-week break from training may only delay the increase in strength achieved with RT. Non-significant correlation between LP and BC strength increases indicates that RT-induced strength gains may not occur similarly in the upper and lower limb muscles. The association observed in TraDeRe in the improvements in LP strength between the first and second 10 weeks of RT indicates that the strength responses to RT can be reproducible and, thus, mainly driven by physiological factors.

HYPERTROPHIC LOADING-INDUCED AVERAGE CONCENTRIC POWER AND ELECTROMYOGRAPHIC RESPONSES DIFFER IN LEG PRESS VS. SMITH-MACHINE BACK SQUAT

KOTIKANGAS, J., WALKER, S., HÄKKINEN, K., PELTONEN, H.

UNIVERSITY OF JYVÄSKYLÄ

INTRODUCTION: Back squat and leg press exercises involve the same major muscle groups, but they differ in their biomechanical properties [1,2]. These differences may affect, e.g., the magnitude of activated muscle mass and muscle activation strategies during resistance exercise [1-3]. Thus, we examined how Smith-machine back squat vs. leg press exercises affected the progression of neuromuscular fatigue within typical hypertrophic loadings.

METHODS: 10 recreationally active males performed hypertrophic loadings (5x10-RM, rest 1.5 min) in Smith-machine back squat (SS) and leg press (LP). Average concentric power (AP), and electromyographic activity of vastus lateralis (VL), vastus medialis (VM), rectus femoris (RF), quadriceps femoris, i.e., the averaged activity of VL, VM and RF (QF), biceps femoris (BF) and gluteus maximus (GLU) muscles were recorded during the concentric phases of selected repetitions within all loading sets. Blood lactate concentrations (BL) were measured before, after SET3 (MID) and after the loadings.

RESULTS: The total work performed during SS was significantly higher ($p<0.001$), and a greater relative decrease in AP (-21¬±3%) occurred during SS ($p<0.05$). Significant effects for loading were observed in QF, VM, VL, GLU and BF ($F(1,9)>6.390$, $p<0.05$, $\eta p2>0.415$), so that normalized sEMG values were significantly greater during SS ($p<0.05$). Significant loading × set interactions were observed in VL ($F(2,18)=4.433$, $p<0.05$, $\eta p2=0.295$), RF ($F(1.1,9.9)=8.830$, $p<0.05$, $\eta p2=0.495$) and QF ($F(2,18)=5.453$, $p<0.05$, $\eta p2=0.377$) indicating greater relative increases during LP within SET5 in VL (+31±13%, $p<0.05$) and SET3 and SET5 in both RF (+17±6 and +46±15%, respectively) and QF (+18±6 and +33±12%, respectively, $p<0.05$). Significant loading × set × repetition interaction for RF was found ($F(4,36)=2.680$, $p<0.05$, $\eta p2=0.229$) indi-

cating greater relative increases in RF during the repetitions of SET5 of LP. A significant loading × time interaction was found in BL ($F(1.7,18.3)=4.610$, $p<0.05$, $\eta p2=0.295$), so that BL was significantly higher in MID of SS ($p<0.01$).

CONCLUSION: The greater total work performed during SS was accompanied by greater muscle activation measured by normalized sEMG set-to-set. These factors resulted also in larger acute neuromuscular fatigue observed as a greater decrement in AP during SS. This acute neuromuscular fatigue may explain even decreased sEMG during the latter part of SS. The different hip joint positions between the exercises could also explain differences in sEMG. In LP, the hip joint remains flexed, and thus hip extensors (e.g., GLU) are unable to produce force optimally and possibly placing a greater demand for QF to complete work observed as greater relative increases in sEMG [2,4]. The flexed hip position may also enable RF to act as a knee extensor and take a greater role in force production while fatigue accumulates during LP [5].

OP-BM02 Neuromuscular Physiology: Fatigue

MOTOR UNIT BEHAVIOUR ADJUSTMENTS DIFFER DURING INTERMITTENT AND SUSTAINED ISOMETRIC KNEE EXTENSION TASKS TO FAILURE

VALENCIC, T.1, ANSDELL, P.2, BROWNSTEIN, C.3, HOLOBAR, A.4, ŠKARABOT, J.1

1 LOUGHBOROUGH UNIVERSITY, UK; 2 NORTHUMBRIA UNIVERSITY, UK, 3 NEWCASTLE UNIVERSITY, UK; 4 UNIVERSITY OF MARIBOR, SLOVENIA

INTRODUCTION: Performance fatigability is associated with adjustments in motor unit (MU) discharge behaviour (1, 2). Whilst fatigability is known to vary with task demands (3), it remains unclear whether the associated modulation in MU discharge is also task dependent. This study examined and compared MU behaviour adjustments during two different submaximal isometric tasks to failure.

METHODS: Nine participants (1 female) completed an intermittent (INT; 11 seconds ramp contraction, 4 seconds rest) and a sustained (SUS) isometric knee-extension task to failure at 50 and 20% of maximal voluntary contraction (MVC) force, respectively. MVCs were performed before and immediately after each task, with voluntary activation (VA) and quadriceps-potentiated resting twitch force (Qtw) assessed using femoral nerve stimulation. During each task, high-density surface electromyography (EMG) signals were recorded from vastus lateralis (VL) and medialis (VM) and decomposed into discharge timings (4) in nonoverlapping windows of 3 contractions or 30 seconds for INT and SUS, respectively. Identified MUs were tracked from recruitment to task failure using an iterative process of MU filter optimisation and application (5) in overlapping windows across task duration. Mean discharge rates (MUDR) at target force, and recruitment (MURT) and derecruitment (MUDRT) thresholds during each contraction in INT were quantified for tracked MUs. Global EMG amplitude and force steadiness were also quantified at the target force throughout each task. All variables were averaged within ten windows of 10% of the time to task failure (TTF). Linear mixed models were used to assess whether the outcome variables are predicted by TTF, muscle, and task.

RESULTS: TTF was 531±134 and 217±82 seconds for INT and SUS, respectively. MVC force, VA, and Qtw decreased at task failure ($p\leq0.0001$), with similar decrements in both tasks. Global EMG amplitude increased ($p<0.0001$) to a similar degree during both tasks ($p=0.4912$). Force steadiness decreased with time ($p<0.0001$), with a greater decrease during SUS compared to INT ($p=0.0147$). VL and VM MUDR was modulated during both tasks ($p<0.0001$), with different, distinct patterns found between the two tasks ($p<0.0001$). During SUS, MUDR was decreased between 40% to 80% TTF ($p<0.010$) before returning to baseline, whereas during INT, MUDR remained stable until 50% TTF, after which it increased above baseline and continued to increase until task failure ($p<0.010$). During INT, both VL and VM MURTs and MUDRTs gradually decreased with time (both $p<0.0001$).

CONCLUSION: Our results provide evidence that adjustments in MU discharge behaviour during submaximal isometric contractions to task failure depend on task demands.

SEX DIFFERENCES IN MUSCLE FATIGUE DEVELOPMENT AND INTRAMUSCULAR METABOLIC PERTURBATIONS DURING INTERMITTENT ISOMETRIC EXERCISE

COLOSIO, M., LAMBOGLIA, M., PASTORIO, E., GATTI, M., VERNILLO, G., TEMESI, J., FIORENZA, M., BANGSBO, J., HOSTRUP, M., PORCELLI, S.

UNIVERSITY OF MILAN

INTRODUCTION: Women are more muscle fatigue resistant than men during isometric tasks (3). Studies have suggested that a number of physiological factors lead to slower fatigue development in women than men during exercise, ultimately prolonging time to task failure in women at the same relative intensity (1,3). It remains unknown whether exercise-related accumulation of metabolites within skeletal muscle differentially affects fatigue development in women and men. The aim of this study was to investigate sex-specific differences in intramuscular metabolic perturbations during exhaustive intermittent isometric knee-extensor exercise.

METHODS: Fourteen males (M) (26±2ys) and 14 eumenorrheic women (W) (24±3ys) visited the laboratory twice. In visit 1, isometric knee-extensors critical torque (CT) was estimated by a 5-min all-out test (3s on/2s off) (2). In visit 2 (W in luteal phase), participants performed intermittent isometric knee-extensor exercise to task failure at 110% of CT. To determine knee-extensors fatigability maximal voluntary isometric contraction (MVIC), voluntary activation (VA), evoked high-frequency doublet (Db100) and potentiated twitches (St) were evaluated before (PRE), at 9 min (MID), and at task failure (POST). At the same time points, intramuscular levels of pH, ATP, PCr and Cr were determined in vastus lateralis muscle biopsies. Within-time and between-sex differences were evaluated by 2-way repeated measures ANOVA.

RESULTS: At PRE, MVIC torque was higher in M than W (259±70 vs 152±24Nm; P<.001). At MID, MVIC torque was decreased more in M than W (-43±9 vs -34±8% from PRE; P<.05). At POST, no differences in MVIC torque loss were observed between M and W (-55±7 vs -53±6% from PRE), while time to task failure was shorter in M than W (1017±498 vs 1511±506s; P<.01). VA and Db100 decreased over time (P<.001) to a similar extent in M and W. St torque loss was higher in M than W (-45±13% vs -37±15%; P<.05) at MID, whereas no sex-specific differences were observed at POST. No changes in muscle [ATP] were found over time. Muscle pH decreased and [Cr] increased over time (P<.001) without sex-specific differences. From PRE (M:64±19 and W:64±21mmol*kgDW-1) muscle [PCr] declined during exercise in M (MID: 45±13; POST: 34±13mmol*kgDW-1, both P<.05) but not in W (MID: 55±13; POST: 50±16 mmol*kgDW-1).

CONCLUSION: Women and men showed similar exercise-induced torque loss and intramuscular metabolic perturbations after intermittent isometric knee-extensor exercise performed at same relative target force. However, women can sustain the task for longer duration and are better to preserve muscle [PCr] during the task. These results indicate that a faster depletion of muscle PCr and, hence, accumulation of intramuscular inorganic phosphate may contribute to the faster fatigue development in men than women during submaximal intermittent isometric exercise.

MIND OVER MUSCLE? A DECEPTIVE STUDY ON NEUROPHYSIOLOGICAL MECHANISMS ASSOCIATED WITH STOPPING EFFORT

MATTA, P.M., GLORIES, D., ALAMIA, A., BAURÈS, R., DUCLAY, J.

UNIVERSITÉ PAUL SABATIER

INTRODUCTION: While physical performance has long been thought to be limited only by physiological factors, many experiments denote that psychological ones can also influence it (1). An interesting paradigm to study the influence of psychological factors on performance is manipulating them without participants' awareness (2). Using this methodology, previous results (3) showed a performance improvement during a cycling task performed to exhaustion when the clock was covertly slowed down by 10% compared to a condition where the clock was normal. However, the neurophysiological mechanisms underlying this performance improvement remain unclear to date. Therefore, the purpose of the current study was to investigate the neurophysiological adaptations associated with improved performance when the clock is unconsciously slowed down.

METHODS: Twenty-four subjects participated in five identical sessions during which they had to maintain an isometric knee extension against a fixed resistance (20% of their maximal torque) for as long as possible. A digital clock was continuously displayed in front of them to keep them constantly informed on their performance (i.e., holding time). During one of the two last sessions, clock calibration was slowed down at 90% of its actual speed (i.e., 100 s displayed = 111 s real), unbeknownst to the subjects. Neuromuscular fatigue was assessed over these last two sessions – defined as Normal and Biased respective to the clock calibration – by pre- to post-exercise changes in quadriceps maximal voluntary torque (MVT), voluntary activation level (VAL), and potentiated twitch (Tw). The kinetics of neuromuscular fatigue accumulation during the task were quantified using the root mean square of quadriceps electromyographic activity (RMS-EMG).

RESULTS: Real holding time was significantly higher in the Biased session compared to the Normal session ($p < 0.05$). Neuromuscular fatigue, assessed by MVT, VAL, and Tw pre-post comparison, was present in both Normal and Biased sessions ($p < 0.05$ for all) but without difference in magnitude between sessions ($p > 0.05$ and $BF < 0.3$ for all). Further analyses (using computational modeling) on intra-task RMS-EMG data revealed a neuromuscular fatigue accumulation following subjective rather than real time for individuals whose performance strictly improved when the clock was slowed down (N = 16).

CONCLUSION: Our study showed a significant performance improvement when the clock was slowed down without increasing the associated neuromuscular fatigue. This specific pattern relies on a fatigue accumulation dependent on subjective rather than real time for participants who improved their performance when the clock was slowed down. These

results support a psychological influence on neuromuscular processes, thus expanding the literature on mind-body influence.

AETIOLOGY OF NEUROMUSCULAR FATIGUE DURING REPEATED SPRINTS IN SYSTEMIC VS LOCALIZED HYPOXIA.

MOUGIN, L.1, DI DOMENICO, H.1, HINTZY, F.1, HAYES, M.2, RUPP, T.1

1 SAVOIE MONT-BLANC UNIVERSITY, LIBM, EA 7424, CHAMBÉRY, FRANCE. 2 ENVIRONMENTAL EXTREMES LABORATORY, SCHOOL OF SPORT AND HEALTH SCIENCES, UNIVERSITY OF BRIGHTON, EASTBOURNE, UK.

INTRODUCTION: Systemic hypoxia (SH) and blood flow restriction (BFR) are two methods used to improve the ability to repeat sprints [1,2]. Previous research explored the impact of these altitude-simulation modalities on neuromuscular fatigue (NMF) during upper-limb repeated sprint exercise (RSE)[3], but, methodological considerations such as time between cessation of exercise to measurement and the lack of individualization of exercise modalities are still preventing observations in the lower limbs. The aim of this study was to compare the impact of SH and BFR on the kinetics and aetiology of NMF during lower limb cycling RSE, using an innovative instrumented cycle-ergometer allowing measurements between sprints.

METHODS: 15 healthy males (22±4 yrs; 70±8 kg) performed 2 trials of RSE (10-sec sprint / 28-sec recovery) on a custom ergometer until an individualized task-failure criteria (i.e. 30% decrease in sprint mean power). Exercises were done in 2 randomized hypoxic conditions: BFR (45% of arterial occlusion) and SH (FiO_2=0.13) Maximum voluntary contraction of the quadriceps (MVC), central [voluntary activation (VA)] and peripheral alterations [twitch (Pt)] were evaluated pre and immediately (i.e. no delay) post each sprint. For each RSE, sprints were expressed as a percentage of the total number achieved until task-failure. Individual data were extrapolated at 0, 25, 50, 75 and 100% of the RSE. Throughout the protocol, peripheral oxygen saturation (SpO_2 by pulse oximetry) and quadriceps muscle oxygenation (TSI by near-infrared spectroscopy) were recorded. Repeated measure ANOVAs and Holm correction for post-hoc tests were performed.

RESULTS: Subjects completed 8 ± 4 sprints with BFR and 7 ± 3 sprints in SH, with no significant difference between conditions. MVC and VA were decreased in both conditions but perturbations were exacerbated in BFR (e.g. MVC pre-post: -46±14% BFR vs -24±12% SH, $p<0.001$; VA pre-post -19±15% BFR vs -5±8% SH, $p<0.001$, respectively $F(1,14)=23$ & $F(1,14)=12$). For MVC & VA, condition effects were significant from 50% to 100% ($p<0.05$). Pt similarly decreased from 0 to 75% in both conditions (-35±26% BFR vs -30±20% SH) and then plateaued ($F(1,14)=0.1$; $p=0.902$). Decreases in SpO_2 (pre-post: -3±2% BFR vs. -30±8% SH; $p<0.001$) and TSI (pre-post: -23±4% BFR vs. -27±5% SH; $p<0.001$) were impacted to a greater extent in SH.

CONCLUSION: The number of sprints performed during RSE until an individualized task-failure threshold was similar under SH and BFR but NMF and its aetiology differed. Peripheral alterations occurred from the beginning to 75% of the exercise duration and were similar in both hypoxic modalities, while the exacerbated decline in MVC under BFR from mid-exercise was concomitant with additional central alterations that may be due to higher III/IV afferents activity. Finally, BFR did not emphasize localized hypoxia compared to SH.

IMMEDIATE AND PROLONGED EFFECTS OF SUBMAXIMAL ECCENTRIC VS. CONCENTRIC FATIGUING PROTOCOLS ON HAMSTRINGS NEUROMUSCULAR FUNCTION

CORCELLE, B., MONJO, F., DA SILVA, F., GIODA, J., GIACOMO, J.P., BLAIN, G.M., COLSON, S.S., PIPONNIER, E.

UNIVERSITÉ CÔTE DAZUR

INTRODUCTION: Repetition of intense hamstrings contractions, such as during maximal sprints, induce hamstrings neuromuscular fatigue from peripheral and central origin [1]. However, it is unknown whether such fatigue is mainly determined by the repetition of eccentric (ECC) or concentric (CON) hamstrings contractions during exercise and whether it is a short or long-lasting phenomenon. Given that neuromuscular fatigue is considered as a risk factor for hamstrings strain injuries [1], determining the effects of separate repeated ECC and CON contractions during fatiguing exercise is crucial to better understand the etiology of hamstrings neuromuscular fatigue. Our study was thus designed to compare the immediate and prolonged effects of unilateral ECC or CON repeated contractions on hamstrings neuromuscular function.

METHODS: On separate days, sixteen men repeated sets of five unilateral hamstrings contractions at 80% of the ECC or CON 1 repetition maximum (1RM) with a voluntary controlled knee angular velocity (i.e., ~ 10°/s). Contractions were performed on a dedicated hamstrings ergometer until a 20% decrement in maximal voluntary isometric contraction (MVC) torque was reached. Each set was separated by 25-s at rest during which hamstrings neuromuscular function was assessed. Exercise-induced hamstrings fatigue was quantified using pre- to immediately after (POST) and 24 hours (POST 24)

after exercise changes in high and low frequency potentiated paired twitches torques (T100 and T10, respectively) as well as voluntary activation level (VA). T100 and T10 were evoked by electrical myostimulations and VA was measured using the interpolated twitch technique.

RESULTS: Compared to baseline, independently of the contraction type, significant reductions in T100 (ECC: -13.3%; CON: -9.7%; $p < 0.001$), T10 (ECC: -5.1%; CON: -11.8%; $p < 0.05$) and VA (ECC: -3.0 %; CON: -2.4%; $p < 0.001$) were found at POST. However, these reductions did not persist at POST24.

CONCLUSION: For the same MVC torque drop (i.e., ~ 20%), repeated ECC or CON contractions provoked similar levels of peripheral and central hamstrings neuromuscular fatigue. This suggests that the etiology of hamstrings neuromuscular fatigue during such exercise does not depend on contraction type. These findings may find applications in hamstrings injury prevention methods. Indeed, while solely ECC strengthening is usually prescribed on the field to improve hamstrings force and fatigue resistance [3], the combination of ECC and CON strengthening protocols should also be considered because fatigue during repeated sprints likely arises from the repetition of both contraction type.

IS-SH01 Sport and climate change: challenges and opportunities

OUTDOOR SPORTS AND THE ENVIRONMENT: BALANCING ACCESSIBILITY AND SUSTAINABILITY

SCHUT, P.

UNIVERSITÉ GUSTAVE EIFFEL

Current environmental issues raise questions about the relationship between man and the environment. This relationship is at the basis of outdoor sports, which have enabled people to discover and explore exceptional places through sport. There is a certain constancy for the aesthetic admiration of places. But the efforts to make the sites accessible, which are inseparable from tourism, have contributed to altering the sites before the emergence of ecological or sustainable development ideas have led practitioners to adopt a more responsible approach. The purpose of this paper is, through examples taken from several physical activities, to show the evolution of the relationship with the natural environment and the transformations between admiration, understanding and protection that practitioners have been able to put forward in their activities.

SUSTAINABILITY THROUGH TECHNOLOGY? POTENTIALS, RISKS, AND PARADOXES IN SPORT ORGANISATIONS' SUSTAINABLE TECHNOLOGY STRATEGIES

TJØNNDAL, A.

NORD UNIVERSITY

Technology is a vital enabler in sport organisations' efforts to contribute to sustainable development and the mitigation of climate change. For instance, technology enables the development of new sports apparel and equipment made from sustainable materials. Technology also enables new digital forms of sport participation and consumption that may reduce sports' carbon emissions. Additionally, new 'smart stadiums' use sustainable technology strategies to make sport events resource-saving and minimize emissions. The aim of this paper is to examine the role of technological innovation in sport organisations' strategies to mitigate climate risk and become more ecologically sustainable. The main argument in the paper is that the relationship between technology and sustainability in sports is often simplified. Using empirical examples such as Bodø/Glimt's plans for a new 'smart' football stadium, the green sport event EcoTrail Oslo, and Nofir's project of recycling fishing nets to goal netting in team sports, the paper highlights potentials, risks, and paradoxes in sport organisations' sustainable technology strategies.

PERFORMANCE OR SUSTAINABILITY? TENSIONS BETWEEN (ELITE) SPORT LOGICS OF PERFORMANCE AND REDUCING ENVIRONMENTAL IMPACT

SVENSSON, D.

MALMÖ UNIVERSITY

In the face of climate change, and driven by the logic of sportification, many sport landscapes have become more dependent on advanced technology. In this paper, we analyze how sport practitioners view the landscapes in which they conduct their training and competitions. Specifically, we explore the role of technology in balancing performance and environmental sustainability by analyzing two cases that are both impacted by climate change. The first case focuses on the role of sustainable development among individuals who have alpine skiing as their profession and lifestyle, primarily as ski instructors. Their relation to sport landscapes and seasonality over two decades explain how the environment and

climate has changed and affected the possibility to ski and having skiing as a living (or not). There is a tension between the importance of technology in artificial snow production to sustain a full season, and a more caring attitude towards the nature and mountains. The desire to work with skiing is strong and, to some extent, work towards environmental sustainability. The second case zooms in on cross-country skiers, and the tensions between (elite) sport logics of performance and reducing the environmental impact (Backman & Svensson, 2022). We argue that the tension between performance and environmental sustainability becomes explicit in relation to climate change, and that sport with its long tradition of regimentation and standardization regarding technology and performance (Loland, 2018) has the potential to become a driving force in climate-related adaptations.

OP-AP19 Swimming: Training and Testing

THE INTERPLAY BETWEEN ACTIVE DRAG, ARM STROKE EFFICIENCY AND PROPULSIVE POWER AS DETERMINANTS OF FRONT CRAWL SPRINT PERFORMANCE

PETERSON SILVEIRA, R.1, RAINETEAU, Y.1,2, PLA, R.2, BIDEAU, B.1, NICOLAS, G.1, BIDEAU, N.1

1 M2S LAB – LABORATOIRE MOVEMENT SPORT SANTÉ, UNIVERSITÉ RENNES 2, RENNES, FRANCE. 2 FÉDERATION FRANÇAISE DE NATATION, PARIS, FRANCE.

INTRODUCTION: Swimming performance depends on the balance between mechanics and energetics. Athletes must maximize propulsion (thus increasing the metabolic input) while minimizing hydrodynamic resistance (thus decreasing the energy cost) (1). Moreover, identifying key predictors of performance obtained from field tests is of particular interest for coaches, performance analysts and athletes. Therefore, the aim of this study was to verify in-field the association between active drag coefficient, propulsive power, propelling efficiency, and maximal sprint performance in front crawl.

METHODS: Male and female competitive swimmers of different levels participated in this study (n=51). They performed four all-out semi-tethered front crawl sprints with increasing loads (0.1, 2.0, 4.0, and 6.0 kg) using an electromechanical device (1080 Sprint, Sweden). To avoid major changes in the duration of each trial as the load increased, swimmers were asked to swim 25 m in the first trial (0.1 kg), 25 m in the second trial (2.0 kg), 20 m in the third trial (4.0 kg), and 15 m in the fourth trial (6.0 kg). Average swimming speed and semi-tethered force were obtained from ~10-20 m in the unloaded trial. The number of strokes executed before and within this window was computed and used as a reference to calculate the average speed and semi-tethered force in the other trials (i.e., 2.0-6.0 kg). A linear regression of the semi-tethered force vs swimming speed relationship was used to obtain input parameters to be included in the calculation of Drag, drag coefficient, and propulsive power using the Velocity Perturbation Method (2). The arm stroke efficiency was obtained from the ratio of the average forward speed and the average tangential hand speed (1,3). A stepwise regression was used to identify the association between the selected parameters and maximal sprint performance in front crawl swimming (α=5%).

RESULTS: Two models predicting front crawl sprint performance were obtained from the stepwise regression: (i) including propulsive power (R^2=0.797; p<0.001), (ii) including propulsive power and active drag coefficient (R^2=0.965; p<0.001). The arm stroke efficiency was excluded by the stepwise regression and, individually, presented a negligible correlation with maximal swimming speed (r=-0.274; p=0.026).

CONCLUSION: Propulsive power and active drag coefficient obtained using a coach-friendly semi-tethered swimming protocol are strongly related to maximal front crawl sprint performance. Despite its importance in converting the total mechanical power into useful propulsive power, and its known correlation with swimming economy (an important determinant of performance in longer distances) the arm stroke efficiency was not a strong predictor of sprint performance in front crawl.

HAND THRUST DURING FREE AND TETHERED SWIMMING: AN ANALYSIS OF ASYMMETRY

RUSSO, G.1, COLORETTI, V.1, FANTOZZI, S.2, CORTESI, M.1

UNIVERSITY OF BOLOGNA

INTRODUCTION: Analyzing athletes' parameters, such as forces during swimming, is essential to enhance performance (1,2).

The use of wearable sensors could facilitate this process due to their cost-effectiveness, ease of use, and ecological approach.

In this research, we investigated how hand thrust forces vary according to two swimming tests (tethered vs. free) and between the two hands (dominant vs. non-dominant). We hypothesized larger forces in terms of average force (Fmean),

impulse (I), and peak force (Fpeak) in tethered compared with the free swimming and in the dominant compared with the non-dominant hand.

METHODS: Eleven skilled swimming athletes (age = 15.4 ± 0.5y.; body mass = 58.0 ± 7.1Kg; stature = 168.4 ± 5.0 cm) performed a 10-second tethered front crawl only arms test (Tet), and 10 seconds free front crawl only arms test (Free) wearing two wearable pressure sensors, one for each hand. The thrust force of each hand was estimated as the product of differential pressure (palmar minus dorsal side) and hand surface. Considering circle-shaped hand kinematics, only the horizontal component of hand thrust force was used for the analysis. Average force (FMEAN), impulse (I), average peak (FPEAK), and instantaneous (by means of Statistical Parametric Mapping, SPM) were analyzed as a function of swimming condition and dominant/non-dominant hand. The symmetry index (SI) was analyzed as a function of swimming conditions.

RESULTS: Results indicated larger Fmean, Fpeak, and I during Tet compared to the Free condition ($F > 4.23$, $p < .05$; Fmean: Tet = 34.0 ± 9.7 N vs. Free = 28.7 ± 7.8 N; Fpeak: Tet = 74.6 ± 22.0 N vs. Free = 66.8 ± 15.2 N; I: Tet = 28.0 ± 5.3 Ns vs. Free = 22.0 ± 5.3 Ns). Whereas SI was non-significant. SPM highlighted a larger Fmean in Tet condition only at the beginning of the stroke (entry phase, from 7 to 28% of the cycle).

In addition, non-significant differences were observed for Fmean between the hands ($p > .05$), and SPM confirmed these results ($p > .05$). However, larger Fpeak and I in the dominant compared with the non-dominant hand were found ($F > 11.11$, $p < .05$; Fpeak: dominant = 65.3 ± 15.9 N vs. non-dominant = 62.7 ± 14.4 N; I: dominant = 26.3 ± 8.0 Ns vs. non-dominant = 23.5 ± 5.6 Ns).

CONCLUSION: The swimmer appears to exert larger hand propulsion in tethered- than free- swimming. However, our findings of the symmetry model and the hand-propelling balance during tethered- and free-swimming were not conclusive, and further investigations could help in better understanding this phenomenon (3).

APPLYING SEVERE AND EXTREME INTENSITY SWIMMING TRAINING IN THE SAME SESSION: EFFECT OF SET SEQUENCE ON PHYSIOLOGICAL RESPONSES AND PERFORMANCE

NIKITAKIS, I., PAPADOPOULOS, K., PRAGIAS, E., PARADISIS, G., BOGDANIS, G., TOUBEKIS, A.

NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS

INTRODUCTION: Swimming training may include sets in various intensities that applied concurrently and with varied order. The sequence of training sets may affect performance and physiological response of the whole session and in each set separately. The aim of this study was to investigate the effect of set sequence on performance and physiological responses in a training session and in each set separately.

METHODS: Twelve swimmers (18.7±3.4 years) performed 50 and 400 m maximal efforts to estimate maximal speed and maximal aerobic speed (MAS), respectively. Training sets of 8x100 m at MAS (set A - severe) and 8x50 m at 95% of the maximal speed (set B - extreme) were planned, both including 30 s of recovery between repetitions. In two randomized order sessions swimmers completed the following set sequences: i) set A - set B (A-B), ii) set B - set A (B-A) with 10 min of passive recovery between sets. Time to complete each repetition and heart rate (HR) were recorded continuously. Lactate concentration [La-] was determined at the start, middle and end of each set and the mean [La-] was calculated. Blood pH, base excess (BE) and bicarbonate (HCO3) were determined before and after each set. Plasma volume percentage changes (ΔPV) after each training set was calculated based on hematocrit and hemoglobin changes. R-R intervals were recorded the night after each session and HRV was calculated. The logarithm of root mean square successive difference (LnRMSSD) was used to examine the effect of the entire session on autonomic nervous system.

RESULTS: Performance in each set separately was not different between sessions regardless of sets sequence ($p>0.05$). Mean HR was not different between sessions in each set ($p>0.05$). Mean [La-] in set A was higher in B-A condition compared to the reverse order (A-B: 6.0±2.4, B-A: 9.0±1.8 mmol·L-1, $p<0.05$). However, in set B, [La-] was similar between sessions ($p>0.05$). Mean pH of the entire A-B session was higher and BE and HCO3 were lower compared to B-A session (pH: A-B: 7.336±0.046, B-A: 7.303±0.033, BE: A-B: -6.6±2.8, B-A: -9.2±2.3 mmol/L, HCO3: A-B: 19.3±2.2, B-A:17.2±1.8 mmol/L, $p<0.05$). However, acid-base parameters in each set separately did not change irrespective to the set sequence ($p>0.05$). ΔPV did not differ between sessions and did not change in each set irrespective to the set sequence ($p>0.05$). Nocturnal LnRMSSD did not differ between sessions and in each set independent of the applied sequence ($p>0.05$).

CONCLUSION: Training sets sequence does not affect performance in each set separately but may influence the entire set physiological responses. The overall effect of the entire training session in parameters determining acid-base balance is magnified when a near-maximum intensity set is followed by a set at MAS compared to the reverse order.

INFLUENCE OF AN INTENSIVE 6-DAY TRAINING PERIOD ON A SUBMAXIMAL PERFORMANCE TEST IN NATIONAL LEVEL YOUTH SWIMMERS

BRANDTS, M., SKORSKI, S., MEYER, T.

SAARLAND UNIVERSITY

INTRODUCTION: Previous studies have reported that the Lamberts and Lambert Submaximal Cycling test (LSCT) can be used to predict performance(1) and monitor fatigue/fitness(2). However, to our knowledge there is no sport specific submaximal test which can be applied for these purposes in swimming so far. Therefore, the aim of the current study was to assess whether a modified swim-specific version of the LSCT (LSCTmod) is responsive to an intensive 6-day training period.

METHODS: Seventeen, German and Dutch national swimmers participated in an 8-day training camp. At day 1 (Pre) and 8 (Post), the LSCTmod was conducted in a 50 m pool. Between day 1 and 8, an intensive 6-day training period was carried out. Before the test, participants were asked for their 400 m personal best time. The LSCTmod consisted of three submaximal stages aiming at 60% (stage 1; 500 m), 80% (stage 2; 500 m) and 90% (stage 3; 200 m) of personal 400 m best times. Participants were provided with an individual 100 m target time corresponding to the intensity of each stage. In between stages there was a 30-second break, during which heart rate (HR) and Borg's rating of perceived exertion (RPE) were obtained. Effects on HR and RPE during the LSCTmod were analysed using a two-way analysis of variance (ANOVA). Results are presented as means±SD for HR and time and median [interquartile range] for RPE. Partial eta squared was calculated as effect size.

RESULTS: For the LSCTmod, 100 m target times were set at 113±7 s for stage 1, 85±5 s for stage 2 and 76±5 s for stage 3. Comparing day 8 to day 1, change in HR was -6±12 bpm, -7±20 bpm and -5±20 bpm and change in RPE was 0 [1], -1 [2] and 0 [2]at stage 1, 2 and 3, respectively. There was no significant main effect of the training camp on HR ($F1,16=3.36$; $P=.070$; $\eta2p=0.03$) nor RPE ($F1,16=1.12$; $P=.292$; $\eta2p=0.01$). A decrease in HR coincided with an equal/increased RPE in 11/18 participants at stage 1, 2/18 participants at stage 2, and 5/18 participants at stage 3.

CONCLUSION: The findings of the current study show that an intensive 6-day training period resulted in a decrease in HR, albeit not significant, and no change in RPE during the LSCTmod. Although, a lower HR and a similar/higher RPE was found in most participants in stage 1, none of them displayed this pattern over all three stages. However, the reliability of the LSCTmod has not yet been investigated and the lack of familiarization might partly explain the results.

EFFECTS OF 12-WEEK CONCURRENT TRAINING ON GENERAL ATHLETIC ABILITY AND SPECIFIC ATHLETIC PERFORMANCE OF PREADOLESCENT SWIMMERS

YIN, X.

SHANGHAI RESEARCH INSTITUTE OF SPORTS SCIENCE

INTRODUCTION: Concurrent training (CT) refers to simultaneous strength training and aerobic endurance training within a training cycle(Wilson, et al. 2012). Due to differences in anthropometric and physiological differences between children and adults, some previous research conclusions cannot be directly applied to children. Hence, the main aim of this study was to analyze and explore the changes of prepubertal swimmers anthropometrics, general motor abilities and swimming performance before and after the concurrent training intervention.

METHODS: In this study, 36 pre-adolescent swimmers were randomly divided into experimental group (EXP, N=40; age = 9.9 ± 0.90 yr.) and control group (CON, N=18; age = 10.0 ±0.60 yr.) from the local Swimming School in Huangpu District. During the 12-week intervention period, the EXP performed water swimming endurance training, 80%-85% 1RM strength and plyometric training, while the CON group performed specific-swimming endurance and land-specific endurance training. After the intervention training, a post-test was conducted on all subjects, and the tests and process were exactly the same as the pre-test.

In addition to static jump(SJ) and countermovement jump(CMJ), all swimmers performed general motor abilities tests consisting of 20m sprinting(SP), 40s sit-up(SU), 40s push-up(PU), standing long jump(SLJ), 15s jumping sidewards (JS), 6min running(RU) from six subtests of Deutscher Motorik-Test 6–18 (Bös and Schlenker 2011), while 50m and 400m freestyle performance was measured in the swimming pool before and after the implementation of CT program.

A 2 (group: EXP, CON) by 2 (time: pre, post) analysis of variance (ANOVA) for repeated measures was executed to determine whether there were a significant interaction and/ or significant differences among swimmers' Repeated Measures of all types of motor tests and freestyle performance, comparing training modalities (EXP group versus CON group)

RESULTS: The test result showed that there were significant interaction for two training groups in regard to repeated measures of SJ($F (1,34)=9.75, P=0.005$), CMJ($F (1,34)=24.74$, $P=0.000$), SLJ($F (1,34)=11.18$,$P=0.003$), JS($F (1,34)=8.2, P=0.009$) and 50m freestyle performance[$F (1, 34) = 4.42$, $p = 0.47$]. After 12 weeks of training, the performance of SJ ($\Delta MD=1.05$, $p=0.037$, $ES=0.83$), CMJ ($\Delta MD =2.0$, $p<0.001$, $ES=1.08$), SLJ ($\Delta MD =0.62$, $p<0.001$, $ES=2.10$), SU($\Delta MD =0.69$, $p<0.001$,

ES=3.0), PU(ΔMD =0.28, p<0.001, ES=1.10), SP(ΔMD =0.28, p<0.001, ES=0.8), JS(ΔMD=0.28, p<0.078, ES=2.23), RU(ΔMD =0.21, p<0.001, ES=0.58), and 50m freestyle(ΔMD =-1.17, p<0.001, ES=0.60) were all improved in EXP compared to before.

CONCLUSION: Concurrent 12-week training was more effective in improving lower-body power, core endurance, coordination, and 50-meter freestyle performance in prepubertal swimmers than specific-swimming endurance training alone. It shows that without increasing the amount of training, the same period of training is more efficient than individual specific endurance training.

OP-AP21 Combat Sports: Training and Testing

ASSESSING THE KEY PHYSICAL CAPABILITIES IN STRIKING COMBAT SPORTS: RELIABILITY AND REPRODUCIBILITY OF A NEW TEST.

GUSCIGLIO, B., MORIN, J.B.

UNIVERSITÉ JEAN MONNET

INTRODUCTION: The rules and technical aspects of combat sports make it difficult to determine key performance indicators [1]. It is well established that striking actions require a combination of explosive strength, power, and speed alongside a well-developed cardiovascular system, particularly the anaerobic system [1, 2]. The Force-Velocity-Power (FVP) and anaerobic assessments used in combat sports were generally upper or lower body dominant [2]. In striking combat sports, the Landmine Punch Exercise (LPE) has a high transfer potential due to similarities with striking skills. Therefore, the main focus of this study was to investigate the reliability and reproducibility of the LPE as a specific neuromuscular and anaerobic assessment for striking combat sports. The second purpose was to compare the FVP obtained by the multiple-points (MP) versus the two-points (TP) method.

METHODS: Ten high-level boxers performed three trials consisting of FVP (both TP and MP methods) and fatigue tests using the LPE. The FVP test consisted of incremental loading (20%, 30%, 40%, and 50% of the body mass) using ballistic bar throws (i.e. LPE). After performing FVP profiles, the load eliciting Pmax was applied for a 30-s all-out LPE effort. A 3D accelerometer (Microgate Gyko Repower, Bolzano, Italy) was used to determine biomechanical variables from the assessments: maximal theoretical force (F0), velocity (V0), power (Pmax), the slope of the relationship (Sfv), peak power (Ppeak), mean power (Pmean), minimal power (Pmin) and a fatigue index (FI%). Analyses of variance and reliability plus reproducibility were tested through intraclass correlation coefficients (ICCs), coefficients of variation (CVs), effect size (ES), and coefficient of correlation while comparisons between the TP and the MP methods were carried out through, paired t-tests, ES, coefficient of correlation and Bland-Altman plots.

RESULTS: Analyses of variance and paired t-tests didn't reveal significant differences for test-retest sessions and methods comparisons, respectively. This was associated with high within-subject intra-session and inter-session reliability and reproducibility, found for both FVP and fatigue test parameters (CVs<10%, ICCs>0.67, ES < 0.2 for F0, V0, Pmax, Sfv, Ppeak, Pmean, Pmin and FI% and r > 0.88) [3, 4]. In addition, the TP and MP methods showed high validity and agreement (F0: r = 0.88, V0: r = 0.95, Pmax: r = 0.96, Sfv: r = 0.93 and all ES were <0.11).

CONCLUSION: The novel LPE test presented in this pilot study is a highly reproducible tool for evaluating both neuromuscular and anaerobic components specific to the discipline. Alongside that main result, athletes and coaches may preferentially use the TP method to reduce fatigue and the time required to perform the testing procedure and to better understand striking performance in combat sports.

NEUROMUSCULAR, PHYSICAL FITNESS, AND COMPETITIVE PERFORMANCE IN HIGH-LEVEL JUDO ATHLETES

FRANCHINI, E.1, GUILHEIRO, L.M.2, MARINO, T.K.2, CAPELLI, L.2

1. UNIVERSITY OF SÃO PAULO; 2. ESPORTE CLUBE PINHEIROS

INTRODUCTION: Judo is a combat sport that requires elevated levels of muscle power, aerobic fitness, strength-endurance and speed for optimal competitive performance [1]. However, little is known about these aspects during the tapering phase and their relationship with competitive performance. Therefore, this study aimed to compare muscle power, aerobic power, strength-endurance, and speed-related variables in male and female judo athletes who won medals (MW) and those who did not (NMW) in a national competition.

METHODS: Nineteen high-level judo athletes (9 males, 23 (22;29) years of age, 81 (73;100) kg of body mass, 4 MW; and 10 females, 22 (20;24) years of age, 63 (53;68) kg of body mass, 5 MW) who were preparing for a Brazilian national-level tournament took part in this study. During the tapering period, athletes executed tests (between 13 and 3 days before competition) to determine peak power for squat and bench press exercises (using loads between 30% and 80% of their one-repetition maximum), long-standing jump, maximal number of repetitions during a chin-up test gripping the judogi, maximum speed in a 5-s uchi-komi test, and maximum aerobic speed in judo uchi-komi test. Values are presented as median and interquartile intervals. Mann-Whitney U-test was utilized to compare MW and NMW within each group. Significance level was set at 5%.

RESULTS: MW and NMW did not differ (p>0.05) in any performance-related variables: squat (W) – male: MW = 914 (900;974); NMW = 878 (751;1007); female: MW = 593 (580;627); NMW = 576 (567;611); bench press (W) – male: MW = 712 (624;789); NMW = 677 (666;697); female: MW = 359 (333;392); NMW = 372 (359;384); long standing jump – male (cm): MW = 259 (243;277); NMW = 270 (263;282); female: MW = 216 (212;222); NMW = 224 (218;225); chin-up (rep) – male: MW = 17 (12;23); NMW = 19 (17;22); female: MW = 13 (12;17); NMW = 9 (8;13); maximum uchi-komi speed (rep/min) - male: MW = 87.7 (87.3;109.7); NMW = 92.5 (86.5;94.4); female: MW = 86.8 (79.2;95.1); NMW = 93.0 (86.1;95.0); uchi-komi maximum aerobic speed (rep/min) - male: MW = 65.3 (62.2;66.7); NMW = 61.2 (55.9;65.1); female: MW = 64.3 (62.2;65.2); NMW = 60.7 (58.5;62.1).

CONCLUSION: Neuromuscular and physical fitness variables during the tapering period did not differ between male or female MW and NMW. It is likely that well-developed neuromuscular and physical fitness are necessary but not sufficient abilities for top-level judo performance.

PILOT DATA OF THE EFFECTS OF MIXED MARTIAL ARTS SPARRING ON AUTONOMIC BRAIN FUNCTION

KIRK, C., MADEN-WILKINSON, T., CHILDS, C.

SHEFFIELD HALLAM UNIVERSITY

INTRODUCTION: Automated pupil light reflex (PLR) is a valid indicator of reduced autonomic brain function with and without loss of consciousness. Feasibility of PLR to identify acute changes in autonomic brain function has not yet been examined in a sports setting. As a combat sport featuring repeated sub concussive head impacts, mixed martial arts (MMA) sparring may provide a model to understand acute PLR changes in response to such trauma. Therefore, the purpose of this pilot study was to explore changes in automated PLR following MMA sparring.

METHODS: 7 MMA athletes (age = 24±3 years; mass = 76.5±9 kg; stature = 176.4±8.5 cm) took part in their regular sparring sessions (8 rounds x 3 mins:1 min recovery). PLR of both eyes was measured (NPi-300, Neuroptics, USA) immediately pre and post sparring. Variables measured were min and max pupil diameter (mm), constriction velocity (CV, mm·s-1), dilation velocity (DV, mm·s-1), PLR latency (s) and 'NPi' (AU) - a proprietary variable representing overall pupil response. Pre-post comparisons were made for: left eye (L); right eye (R); both eyes averaged together; differences between left and right eyes. Statistical differences were indicated by Bayes factors (BF10) ≥3 on paired samples t tests and Cohen's d.

RESULTS: L NPi improved following sparring (BF10 = 5, d = 1.2; PRE = 4.07±0.3 AU; POST = 4.19±0.3 AU). Minimum L pupil size reduced (BF10 = 8, d = 1.5; PRE = 5.6±1.1 mm; POST = 5.2±1.1 mm). There were no changes in R. Both eyes averaged together displayed improved NPi (BF10 = 4; d = 1.2; PRE = 4.1±0.3 AU; POST= 4.2±0.3 AU), decreased max pupil size (BF10 = 3; d = 1; PRE = 5.8±1.1 mm; POST = 5.4±1 mm), decreased min pupil size (BF10 = 4; d = 1.2; PRE = 3.8±0.9 mm; POST = 3.4±0.7 mm) and reduced PLR latency (BF10 = 3; d = 1.1; PRE = 0.23±0.02s; POST = 0.21±0.01s). Each eye had different min sizes both pre (BF10 = 4 d = 1; L = 3.7±0.9 mm; R = 3.9±0.9 mm) and post sparring (BF10 = 4; d = 1.2; L = 3.3±0.7mm; R = 3.5±0.7 mm). Each eye also had different max sizes (BF10 = 3; d = 1.1; L = 5.2±1 mm; R = 5.6±1 mm) and max CV (BF10 = 3; d = 1.1; L = 4.8±1.1 mm·s-1; R = 5.3±0.8mm·s-1) post sparring.

CONCLUSION: Acute improvements to PLR but increased anisocoria occurs following MMA sparring. Improved PLR may result from high intensity exercise arousal. Future studies require repeat series measurements following MMA sparring to measure the decay of these changes and any PLR decrements potentially masked by arousal.

PHYSIOLOGICAL RESPONSES AND ENERGY SYSTEM PROFILING DURING THE SIMULATION OF EPÉE COMPETITIONS IN ELITE FENCERS

YANG, W.

CHA UNIVERSITY

INTRODUCTION: To determine sport-specific characteristics, this study aimed to evaluate physiological responses and energy system contributions during simulated epée competitions in elite fencers.

METHODS: Ten elite male fencers participated in this study. They performed simulated epée (direct elimination; DE) matches. Simulated epée matches consisted of three rounds of three min each, with one min rest between each round. During these competitions, physiological parameters such as heart rate (HRpeak and HRmean), oxygen uptake (V ̇O2peak and V ̇O2mean), metabolic equivalents (METs in V ̇O2peak and V ̇O2mean), and blood lactate concentrations (Peak La– and delta La–; ΔLa–) were determined. Furthermore, energy system contributions (oxidative; WOxi, glycolytic; WGly, and phosphagen; WPCr) using the PCr- La–-O2 method and time-motion parameters were calculated.

RESULTS: Values of HRpeak, HRmean, and WOxi (%) were significantly higher in the second and third rounds compared with the first round ($p < 0.05$, $p < 0.0001$, $p < 0.01$, and $p < 0.0001$, respectively). Values of V ̇O2peak and METs in V ̇O2peak were significantly higher in the first round compared with the third round ($p < 0.05$, respectively). Values of ΔLa–, and WGly (kJ and %) were significantly lower in the second and third rounds compared with the first round ($p < 0.01$, respectively). V ̇O2mean and METs in V ̇O2mean were significantly higher in the second round compared with the third round ($p < 0.05$, respectively). Furthermore, WOxi (kJ and %) was significantly higher in all bouts compared with WPCR and WGly ($p < 0.0001$, respectively). Low positive and negative correlations were seen between WOxi, V ̇O2mean, and sum of attacks and defence times (ADT) and the sum of time without attacks and defences (STWAD) (WOxi vs ADT: r = 0.48; R2 =

0.23, V̇O2mean vs ADT: r = 0.45; R2 = 0.20, WOxi vs STWAD: r = –0.49; R2 = 0.24, and V̇O2mean vs STWAD: r = –0.45; R2 = 0.20, respectively).

CONCLUSION: Direct elimination epée matches include high-intensity intermittent exercise and the oxidative energy contribution is 80 to 90% of the total energy demand. Improving aerobic performance such as the increased ability of energy recovery may support high-intensity intermittent actions during entire epée matches (3 rounds) in elite fencers.

FORCE-VELOCITY-POWER PROFILING USING ISOMETRIC AND DYNAMIC PERFORMANCE TESTING

VIEIRA, A., CUNHA, R., TUFANO, J.

UNIVERSITY OF BRASILIA

INTRODUCTION: The dynamic strength index (DSI) (also known as the explosive strength deficit or dynamic strength deficit) is a ratio between the peak force obtained during a ballistic movement and isometric peak force. In practice, DSI has been described as reliable in athletes and is theoretically able to provide insights about strength training prescription. For example, the resultant DSI could indicate whether an athlete should prioritize force (high-load, low-velocity) or velocity (low-load, high-velocity) training, but DSI is only a single variable that is based on the relationship between two types of peak force, and there is apparently a lack of relationships between DSI and other common performance variables (1). However, maximal isometric strength could be combined with several other maximal dynamic strength (MDS) variables (i.e., kinetic or kinematic variables that can be extracted from jump data) that may better express neuromuscular functioning during performance-related tasks such as jump height (JH) and takeoff momentum. Therefore, we aimed to investigate the relationship between variables obtained from maximal isometric strength combined with fast MDS and jump performance.

METHODS: Fifteen male combat sports athletes (27 ± 5 years, 77 ± 9 kg, 1.76 ± 0.1 m, 14 ± 6% body fat) participated in 2 testing sessions. The first session involved testing familiarization procedures, while during the second session, isometric mid-thigh pull F0 (N), peak force (N), and mean force (N) were measured. Additionally, mean velocity (m/s), JH (m), and takeoff momentum (kgm/s) were gathered from a squat jump (SJ). We then calculated a linear relationship between force and velocity, which allowed us to obtain the slope of the relationship (SFV) and the theoretical velocity at zero force (V0) and Pmax as a function of F0V0·4-1 (2). Pearson's correlations were used to assess the relationships between JH and takeoff momentum with F0, V0, SFV, Pmax, and DSI.

RESULTS: Large relationships existed between takeoff momentum and F0 ($r = 0.54$, $p = .038$) and Pmax ($r = 0.81$, $p < .001$) as well as between JH and V0 ($r = 0.75$, $p = .001$) and SFV ($r = 0.52$, $p = .045$). In contrast, no relationship existed between DSI and jump performance.

CONCLUSION: Maximal isometric strength can be combined with other fast MDS variables that derive from a dynamic task to provide force-velocity-power profiling, which was largely correlated with vertical jump performance in this study.

IS-EX03 JSPFSM-ECSS exchange: Complex effects of acute exercise on cognition

THE MODERATING ROLE OF PRE-TEST PERFORMANCE ON THE AFTEREFFECTS OF ACUTE AEROBIC EXERCISE ON COGNITIVE PERFORMANCE

KAMIJO, K.

CHUKYO UNIVERSITY

An increasing number of studies has focused on the aftereffects of a single dose (i.e., bout) of acute aerobic exercise on cognitive function. Studies on this topic are considered particularly important, as positive findings may motivate sedentary individuals to start exercising (or adhere to an exercise regimen), since repeated daily exposure to acute exercise could lead to long-term cognitive as well as physical health benefits. However, our recent systematic review (Ishihara et al., 2021) found that more than one-third of previous studies did not determine any beneficial effects of acute aerobic exercise on cognitive performance. To identify possible factors underlying the lack of consensus in the literature, we focused on individual differences in pre-test (i.e., baseline) cognitive performance.

In the first study, we conducted a meta-analysis using individual participant data (IPD meta-analysis) to demonstrate that individual differences in pre-test cognitive performance can affect the aftereffects of acute aerobic exercise (Ishihara et al., 2021). Specifically, the beneficial aftereffects of acute aerobic exercise on cognitive performance were greater in participants with lower cognitive performance at pre-test. The second study focused on intraindividual changes in cognitive performance. Specifically, we examined whether the aftereffects of acute aerobic exercise would change depending on circadian rhythms of cognitive performance. The results indicated that the aftereffects of acute aerobic exercise on cognitive performance differ by time of day, with greater beneficial effects following afternoon exercise, starting at 2 or 3 pm, than morning exercise, starting at 10 or 11 am (preliminary data). The post-lunch dip is a well-established phenomenon of decreased cognitive performance between 2 and 4 pm. Therefore, the beneficial aftereffects of acute aerobic exercise are likely to be greater when the level of cognitive performance is low due to circadian rhythms.

Collectively, these findings demonstrate that pre-test performance strongly moderates the aftereffects of acute aerobic exercise on cognitive performance. Accordingly, in acute exercise studies, we should consider pre-test performance, such

as by manipulating task difficulty and/or by controlling for pre-test performance in statistical analyses. Future studies should attempt to create a gold standard for assessing cognitive performance in acute exercise studies.

Ishihara, T., Drollette, E. S., Ludyga, S., Hillman, C. H., & Kamijo, K. (2021). The effects of acute aerobic exercise on executive function: A systematic review and meta-analysis of individual participant data. Neurosci Biobehav Rev, 128, 258-269.

THE INTERACTION OF ACUTE EXERCISE, STRESS AND COGNITION IN CHILDREN AND PREADOLESCENTS

LUDYGA, S.

UNIVERSITY OF BASEL

The number of children and adolescents reporting moderate to high stress increased over the last decades, with evaluation stress they face in the school setting being one of the underlying causes. While high stress is known to impair cognitive performance, acute exercise has been reported to elicit transient cognitive benefits. Consequently, antecedent exercise has the potential to protect from the negative consequences of stress on cognitive performance. In turn, stress might also influence the temporary effects of acute exercise on cognitive performance. We aim to provide insights into the complex interplay of exercise, stress and cognition by a series of experimental studies.

In the CASPA trial, preadolescent children completed a single, moderately-intense exercise bout on a cycling ergometer or a control task, followed by a the Trier Social Stress Test for Children. The Stroop task was administered in regular intervals. The stress response was measured from salivary cortisol. The results showed that stress affected performance on trials with low inhibitory demand (low difficulty), with a more pronounced slowing of reaction time in participants, who performed an antecedent exercise bout. In the FARADISE trial, we used a randomized cross-over design to investigate the influence of stress on the effects of acute exercise in children with Autism Spectrum Disorder. Participants performed tasks assessing executive function (Affective Go/NoGo paradigm) and social-cognitive abilities (Face and object categorization paradigm) before and after a single, moderately-intense exercise bout on a cycling ergometer or a control condition (remain seated on a cycling ergometer with no pedal movement). Salivary cortisol and heart rate variability were collected in regular intervals throughout both conditions. Our results showed that exercise led to increased levels of stress and at the same time, impaired the ability to detect faces. In contrast, response inhibition was not affected by the acute exercise bout and remained unchanged.

Our findings provide insights into the complex interplay of stress, exercise and cognitive performance in children and preadolescents. Acute exercise seems to elicit a psychophysiological state, during which the negative influence of stress on specific cognitive functions is increased. This indicates that antecedent exercise does not protect from stress and should be avoided prior to a stressful situation. Moreover, an exercise-induced increase in stress may cancel benefits for higher-order cognition and even impair specific social-cognitive abilities in children with Autism Spectrum Disorder. Consequently, exercise may not always improve cognitive performance, especially when exercise is associated with stress.

THE IMPACT OF PARTICIPANT CHARACTERISTICS ON THE BENEFICIAL EFFECTS OF ACUTE EXERCISE IN CHILDREN

RAINE, L.

NORTHEASTERN UNIVERSITY

Obesity is an epidemic, affecting more than 340 million children and adolescents worldwide. This occurs alongside decreased rates of physical activity (PA). Unfortunately, a growing body of research (ours included) suggests these problems were made worse with the COVID-19 pandemic. Obesity and physical inactivity are related to increased risk of developing diabetes, cardiovascular diseases, cognitive decline, and a variety of other health challenges. Fortunately, acute exercise has been shown to benefit cognitive health and academic achievement. Interestingly, these benefits may be enhanced or blunted based on participant characteristics.

For example, 47 children (15 females, 9.64±0.12 years) completed two, randomized and counterbalanced 20-minute interventions: acute PA (treadmill walking at ~65% HRmax) and seated rest (control) on separate days, followed by an educational lesson in a VR classroom. Children then completed a quiz about this lesson. Quiz performance was z-scored across interventions by lesson. Results suggested that children learn better following acute PA (z-score= 0.16±0.13) compared to seated rest (z-score=-0.16±0.14; t=2.29, p=0.026)) and indicate that a single bout of PA may positively impact learning outcomes. We subsequently bifurcated children by IQ and found that those with lower IQ had a significantly greater benefit of exercise compared to their higher IQ peers (p=0.04). This suggests that acute PA may not only improve learning outcomes, but that it may be particularly beneficial for certain children. In a similar study (Raine et al., 2020), we investigated the impact of acute PA on children's performance on a cognitive task. This investigation included 116 children (51 females, 9.88±0.06 years). Analyses indicated improved task performance (p's=0.001) following the acute PA intervention (20 minutes of treadmill walking at ~65% HRmax) compared to the control condition, with selectively greater benefits for the more challenging task condition. Interestingly, further analyses revealed that greater BMI was related to decreased performance following acute PA (p=0.001); an association not observed following the control condition (p's=0.11). These results suggest that BMI may negatively influence the effect of acute exercise on cognitive performance.

As rates of childhood obesity and physical inactivity continue to increase worldwide, these results have implications for the health and wellness of children. Together these findings demonstrate that acute PA may have differential effects on children based on a variety of health and demographic factors. Findings continue to demonstrate the beneficial effects of acute PA on cognitive tasks as well as learning outcomes. These beneficial effects of PA appear to be blunted in children

with higher BMI and enhanced in children with lower IQ. Thus, future studies should attempt to better understand these differences in order to leverage the benefits of acute PA for children.

OP-MH08 Exercise therapy/HIIT

HOME-BASED HIIT AND TRADITIONAL MICT PRESCRIPTIONS IMPROVE CARDIORESPIRATORY FITNESS TO A SIMILAR EXTENT WITHIN AN EXERCISE REFERRAL SCHEME FOR AT-RISK INDIVIDUALS

HESKETH, K.L., JONES, H., KINNAFICK, F., SHACKLETON, S., SHEPHERD, S.O., WAGENMAKERS, A.J.M., STRAUSS, J.A., COCKS, M.

LIVERPOOL JOHN MOORES UNIVERSITY

INTRODUCTION: Exercise referral schemes (ERS) are used to promote physical activity within primary care, however adherence to ERS is often poor. Traditionally, ERS are conducted in a gym or leisure centre setting, with exercise prescriptions based on moderate-intensity continuous training (MICT). Home-based high-intensity interval training (Home-based HIIT) has the potential to reduce perceived barriers to exercise, including lack of time and access to facilities, compared to traditional MICT prescription used with ERS and improve health related outcomes. We hypothesized that Home-based HIIT would mediate greater improvement in cardiorespiratory fitness (CRF) by virtue of greater adherence and compliance to the exercise prescription, compared to MICT.

METHODS: Patients enrolled on an ERS (Liverpool, United Kingdom) were recruited for a pragmatic trial. Participants self-selected either 12 weeks of MICT (45-135 min/week at 50-70% HRmax) or Home-based HIIT (4-9 min × 1 min intervals at ≥80% of HRmax, interspersed with 1 min rest). The primary outcome was change in CRF (VO2 peak) at follow-up (3-month post intervention), using intention-to-treat analysis. Secondary outcomes included blood pressure, body composition (DXA) and insulin sensitivity. An online survey, using open ended questions exploring feasibility and acceptability of Home-based HIT, analysed using a framework approach, was completed post-intervention to explore patient experiences.

RESULTS: 154 participants (age 48 ± 10y; BMI 30.5 ± 6.1 kg/m2) were recruited between October 2017 and March 2019, 87 (56%) participants chose Home-based HIIT and 67 (44%) MICT. VO2peak increased post-intervention in both groups (MICT 3.9 ± 6.0 ml.kg-1.min-1, Home-based HIIT 2.8 ± 4.5 ml.kg-1.min-1, P < 0.001), and was maintained at follow-up (P < 0.001). Fat mass was only reduced post MICT (MICT -1.5 ± 6.3 kg, P = 0.010, Home-based HIIT -0.2 ± 2.0 kg, P = 1.00), but the reduction was not maintained at follow-up (MICT -0.6 ± 5.1 kg, P =0.684, Home-based HIIT 0.0 ± 2.2 kg, P = 1.00). Adherence to the prescribed programs was similar (MICT 48 ± 35%, Home-based HIIT 39 ± 36%, P = 0.77). Qualitative perceptions of Home-based HIT were generally positive, especially its convenience. Interestingly, family providing social support during Home-based HIIT was perceived as a facilitator to adherence.

CONCLUSION: This is the first study to evaluate the use of Home-based HIIT for at-risk individuals enrolled in an exercise referral scheme. Contrary to our hypothesis adherence was poor regardless of exercise prescription. Despite this, CRF improved to a similar extent in both groups and was maintained at 3-month follow-up. We provide evidence that, although not superior, Home-based HIIT could be an effective and popular additional exercise choice for patients within primary care based ERS.

IMPACT OF A 12-WEEK HIGH-INTENSITY INTERVAL TRAINING SCHEME ON CARDIAC STRUCTURE AND FUNCTION AFTER COVID-19

RASMUSSEN, I.E., BERG, R., CHRISTENSEN, R.

CENTRE FOR PHYSICAL ACTIVITY RESEARCH

INTRODUCTION: A large proportion of patients suffer from a persistent reduction in cardiorespiratory fitness after recovery from COVID-19, of which the effects on the heart may potentially be reversed through the effect of high-intensity interval training (HIIT).

METHODS: 28 patients recently admitted to hospitals for COVID-19 were recruited for this investigator-blinded randomized study with a 12-week intervention. Patients were block-randomised to either supervised HIIT exercise group (4x4 minutes, three times a week, n=xx) or standard care (control group, n=xx=). Patients underwent cardiac magnetic resonance imaging scan and a maximal oxygen consumption test (VO2max). The continuous outcomes were analyzed using constrained baseline longitudinal analyses via linear mixed models.

RESULTS: A total of 28 patients were included (HIIT: 58±11 years, 4 females; standard care: 57±9 years, 5 females), LVM increased in the HIIT vs. standard care group with a between-group difference of 6.8 g [95%CI: 0.8; 12.8, ; p=0.029]. Relative VO2peak increased in both groups, by 6.17 mL/kg/min [95% CI: 3.56 to 8.79] (p<0.001) in the HIIT group and by 3.08 mL/kg/min [95% CI: 0.12, 6.04, p=0.042]in the standard care group, with no between-group difference (p=0.11).

CONCLUSION: HIIT is an efficacious rehabilitation tool that specifically targets the heart by increasing LVM in patients previously hospitalized for COVID-19.

IMMUNE RESPONSES TO ACUTE UPPER AND LOWER BODY HIGH-INTENSITY INTERVAL EXERCISE.

GREEN, S.1, WEAVER, S.1, LUCAS, S.1, HODGKISS, D.1, WADLEY, A.1, NIGHTINGALE, T.1,2

1 UNIVERSITY OF BIRMINGHAM, BIRMINGHAM, UK; 2 INTERNATIONAL COLLABORATION ON REPAIR DISCOVERIES , VANCOUVER, CANADA.

INTRODUCTION: A single bout of acute exercise drives a dynamic immune response, which over time may lead to increased immunosurveillance and a lower risk of chronic disease. Prior research indicates that the immune response to moderate-intensity upper-body exercise is diminished in comparison to lower-body exercise. The aim of this randomised crossover study was to compare immune cell responses to acute bouts of upper-body and lower-body high-intensity interval exercise (HIIEUB & HIIELB) and low-to-moderate intensity leg-cycle exercise matched to the absolute upper-body workload (LIIEmatched).

METHODS: Twelve participants (n=9 male and n=3 female, 23±3yrs, 77.1±12.5kg) performed exercise bouts (HIIEUB, HIIELB, LIIEmatched) in a randomised order after performing arm-crank exercise familiarisation sessions and two graded cardiopulmonary exercise tests (CPETs) on each ergometer. For all conditions, participants completed 6x3-minute intervals interspersed with 5x3-minute recovery intervals. Indirect calorimetry was measured throughout each trial. Venous blood was drawn at baseline and immediately post-exercise. Immune cell concentrations were quantified using a haematology analyser and flow cytometry. Data was analysed using a linear-mixed model and are expressed as mean±SD

RESULTS: Peak oxygen uptake (VO2peak) and peak power output (PPO) assessed during the CPETs were significantly higher (P <.001) with leg (40.8±6.5ml/kg/min; 243±54W) compared to arm exercise (32.8±5.7ml/kg/min; 135±28W). The fold change from baseline to post-exercise in lymphocyte concentrations were 0.86±0.50 (HIIEUB), 1.66±0.93 (HIIELB) and 0.20±0.25 (LIIEmatched). Post-hoc comparisons indicated that these fold changes following HIIELB were significantly higher than those following HIIEUB (P=.005) and LIIEmatched (P=.001). Additionally, more detailed phenotypic analysis identified that fold change of CD56dim natural killer cells from baseline to post-exercise was significantly higher in HIIELB (7.38±3.40) compared to HIIEUB (3.96±2.07, P=.002) and LIIEmatched (2.92±1.71, P<.001). HIIEUB was not significantly different to the LIIEmatched trial (P=.576). The fold change in neutrophil numbers were 2.44±1.00 (HIIEUB), 3.61±1.96 (HIIELB) and 0.92±0.56 (LIIEmatched). There were no significant differences between HIIEUB and HIIELB in fold change of neutrophils, however, LIIEmatched was significantly lower compared to both HIIEUB (P=.021) and HIIELB (P<.001).

CONCLUSION: Results indicate greater acute lymphocyte and natural killer cell responses with leg exercise compared to arm exercise at the same modality-specific relative intensity (%Wmax). These findings may have implications for individuals with a lower-body disability who are reliant on performing upper-body exercise to mitigate the risk of chronic diseases. Further research should identify whether there are limb-specific differences in acute and chronic immune cell responses before extrapolating findings from leg-cycle ergometry research to specific clinical populations.

COMPARING THE EFFECTS OF A 12-WEEK MODERATE INTENSITY CONTINUOUS TRAINING AND HIGH-INTENSITY INTERVAL TRAINING PROGRAM ON ANXIETY, DEPRESSION, AND SLEEP QUALITY AMONG PATIENTS WITH ATRIAL FIBRILLATION

ONEILL, C.1, TULLOCH, H.2, REED, J.2

ACADIA UNIVERSITY; UNIVERSITY OF OTTAWA HEART INSTITUTE

INTRODUCTION: Atrial fibrillation (AF) is the most common sustained cardiac arrythmia and is associated with poor mental health (e.g., anxiety and depression) and sleep quality (i.e., insomnia [persistent difficulties in initiating or maintaining sleep]). Among those with AF, moderate-to-vigorous intensity continuous training (MICT) has been shown to improve mental health; yet, whether these improvements may be related to changes in sleep quality is unknown. High-intensity interval training (HIIT) has shown promise for reducing the frequency and intensity of AF symptoms; however, its effectiveness in improving anxiety, depression, and sleep quality compared to MICT remains unclear.

METHODS: A single-centre RCT was conducted. Patients with persistent and permanent AF were randomized (1:1) to either MICT or HIIT. The Hospital Anxiety and Depression Scale (HADS) and the Insomnia Severity Scale (ISI) were administered in a subset of participants (n=58) at baseline and within one week of completing the 12-week exercise interventions. Exercise protocols were completed twice weekly. MICT included aerobic conditioning for 60 minutes (including a 10-15 min warm-up and 15-min cool-down) at intensities within 67-95% of peak heart rate (HR). HIIT included 2x8 minute interval training blocks of 30-second work periods at 80-100% of peak power output interspersed with 30-second active recovery periods (16-minute conditioning phase), and 4 minutes of recovery between the blocks. A repeated measures ANOVA was performed to determine differences over time between groups in the HADS and ISI. Chi-square analyses were used to compare the proportion of patients meeting the MCID for the HADS (i.e., 1.7 points) between groups. Linear regressions were used to test if baseline ISI scores significantly predicted HADS-A and HADS-D scores at 12-weeks.

RESULTS: Of the 58 participants, 49 (MICT=27; HIIT=22) had complete data. No significant differences over time were observed between the groups for the HADS-A (p=0.558) or HADS-D (p=0.555). A significantly greater proportion of those in the MICT than HIIT group experienced clinically meaningful changes in the HADS-A (33% vs. 27%, $\chi 2$=0.93, p=0.006) and HADS-D (33% vs. 27%, $\chi 2$=0.93, p=0.006). No significant differences over time were observed between the groups for the ISI (p=0.271). The ISI scores were found to significantly predicted HADS-D values (β=0.09, p=0.011).

CONCLUSION: Among patients with AF, 12-weeks of exercise training led to clinically meaningful reductions in anxiety and depression severity scores, with the greatest improvements observed following MICT. Sleep quality was a significant predictor of depression severity among patients with AF. Poor mental health and sleep quality are frequently observed

among patients with AF, thus, future research is implored to more thoroughly understand the role of exercise training on these health outcomes to improve the management of this burgeoning clinical population.

TWELVE WEEKS OF ENDURANCE AND CONCURRENT TRAINING IMPROVE VO2PEAK, HEALTH-RELATED QUALITY OF LIFE, FATIGUE AND SYMPTOMS IN SUBJECTS WITH LONG-COVID – A RANDOMIZED CONTROLLED TRIAL

SICK, J., STEINBACHER, V., KOTNIK, D., RECKING, T., KOENIG, D.
UNIVERSITY OF VIENNA

INTRODUCTION: Post-Covid-19, commonly known as Long-Covid (LC), is defined as the presence of long lasting (>12 weeks) Covid-19 symptoms, that cannot be attributed to an alternative diagnosis. Current data suggests a prevalence of up to 34% in non-hospitalized Covid-19 survivors. Thus, the disease imposes a burden on healthcare systems around the globe. Exercise, which has been established as an effective rehabilitation measure for similar conditions, might be beneficial to affected individuals. We therefore hypothesized that physical training increases various health-related outcomes and decreases symptom quantity and severity in non-hospitalized subjects with LC.

METHODS: Forty-six individuals, which did not show any contraindications for physical training and presented at least one LC symptom, according to a list of the National Institute of Healthcare and Excellence, were randomized to two training groups, consisting of either twelve weeks of endurance (ET) or concurrent training (CT) or a non-exercising control group (CG). Thirty participants (23 females and 7 males; 41±13 yrs; n=8 for ED, n=10 for CT and n=12 for CG) completed the study. VO2peak, health-related quality of life (HQoL; RAND SF-36), fatigue severity (FSS) and the number of symptoms were assessed at baseline (T0) and after the intervention or control period (T1). A one-way ANOVA and Tukeys multiple comparisons test were performed to detect differences in mean changes of variables. Paired samples t-test (or a non-parametric alternative) was used to detect differences in means (T0 vs. T1) for each group. Statistical significance was accepted at a level of $p<0.05$.

RESULTS: VO2peak (ml/min/kg) increased significantly from 30.1±6.9 to 34.6±8.1 in ET ($p<0.001$) and from 29.6±5.7 to 32.8±5.8 in CT ($p=0.002$), when comparing timepoints via the paired samples t-test. The ANOVA followed by post-hoc analysis revealed significantly greater changes in VO2peak in ET ($p<0.001$) and CT ($p=0.012$), compared to CG. In all groups, significant increases from T0 to T1 in several subscales of the SF-36 were found. However, only in the subscale "Social functioning" significantly greater changes occurred in ET ($p=0.004$) and CT ($p=0.022$). Fatigue severity scores decreased from 5.1±0.7 to 3.8±1.5 ($p=0.005$) and 4.7±0.8 to 3.8±1.2 ($p=0.007$) in ET and CT, respectively. The average number of symptoms observed at T0 decreased significantly in both ED (from 4.6±2.9 to 2.1±2.1; $p=0.01$) and CT (from 4.6±2.2 to 2.6±1.6; $p=0.019$) at T1. No differences in changes were revealed by the ANOVA for both variables. There were no significant improvements in VO2peak, FSS or the number of symptoms in CG.

CONCLUSION: Participants affected by LC showed improvements in VO2peak, HQoL, fatigue severity and the number of symptoms after 12 weeks of ET and CT, compared to a non-exercising control group. Descriptive data suggests slightly greater enhancements for ET. However, further research is required to support these findings.

EFFECT OF DIFFERENT EXERCISE MODALITIES ON SKELETAL MUSCLE ANGIOGENIC MARKERS IN ADOLESCENT MALES WITH TYPE 1 DIABETES MELLITUS

GUSTAFSSON, J.1, MONTIEL-ROJAS, D.1, KRUSE, R.2, SÄRNBLAD, S.2, PONSOT, E.1
ÖREBRO UNIVERSITY

INTRODUCTION: Type 1 Diabetes Mellitus (T1DM) patients can start developing micro- and macro vascular complications during childhood (1) and are known to have vascular impairments such as endothelial dysfunction, vessel stiffness and reduced capillary density (2). Angiogenesis is the formation of new blood vessels from existing ones and is well documented to occur in healthy individuals in response to various exercise modalities (3). In T1DM however, angiogenesis can be altered and studies on exercise induced angiogenesis in adolescents with T1DM are lacking. The aim of this study was to compare the effects of three different exercise modalities on molecular markers of angiogenesis in skeletal muscle of adolescent males with T1DM.

METHODS: Eight adolescent males (17.5 ± 0.8 years) with T1DM duration >1year attended four sessions, namely a control session followed by exercise tests (VO2max, 1RM) and three randomized exercise sessions (Continuous Exercise (CE), Intermittent Exercise (IE) and Strength Exercise (SE)). One hour after exercise and control a muscle biopsy was taken from the vastus lateralis muscle. RNA was extracted from the sample, followed by one colour microarray-based gene expression analysis as well as enrichment analysis of differentially expressed genes for biological processes and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathways.

RESULTS: Biological Processes related to angiogenesis (blood vessel development, angiogenesis, blood vessel endothelial cell migration, cell migration involved in sprouting angiogenesis) were highlighted following all three exercise modalities, with no exercise specific response being observed. A total 7 KEGG pathways were highlighted across all the conditions,

with AGE-RAGE signaling in diabetic complications as well as Fluid shear stress and atherosclerosis pathways including angiogenesis.

CONCLUSION: In skeletal muscle of adolescent males with T1DM, CE, IE and SE all elicited acute angiogenic response. Analysis of KEGG pathways provide some insight into interplay of other factors in angiogenic signaling in T1DM skeletal muscle.

NO EFFECT OF 12 WEEKS OF AEROBIC TRAINING ON METABOLIC FLEXIBILITY IN OVERWEIGHT MEN WITH AND WITHOUT TYPE 2 DIABETES

LANGE, K.K., HANSEN, M., DAL, M.H., BORCH, J., HELGE, J.W., DELA, F.

UNIVERSITY OF COPENHAGEN

INTRODUCTION: Metabolic flexibility, reflected by the change in respiratory exchange ratio from fasting to an insulin-stimulated state (deltaRER) (1), is the ability to switch from oxidation of predominantly fat to carbohydrates, which is impaired in patients with type 2 diabetes (T2D) (2,3). Exercise is known to improve deltaRER in T2D patients (4). However, most studies perform a euglycemic clamp ([glucose] at ~5mM), which does not represent a habitual glycemic state of T2D. Therefore, we investigate metabolic flexibility during an isoglycemic clamp ([glucose] at the usual level for the individual) in this ongoing study. We hypothesize 1) T2D are less metabolic flexible than healthy matched controls (CON), 2) aerobic training will increase deltaRER in T2D patients.

METHODS: Five male T2D (age 48±6 yrs, BMI 34.8±3.4 kg/m2, HbA1c 70±28 mmol/mol, T2D duration 3.0±2.5 yrs) and six matched male CON (age 50±6 yrs, BMI 36.9±3.1 kg/m2, HbA1c 36±5 mmol/mol) completed a 12-week aerobic training intervention (3x/wk, 45min at 70% of heart rate reserve). Before and after training (T), metabolic flexibility was measured in the 12hr fasting state, using indirect calorimetry (ventilated hood, Q-NRG, COSMED, Italy) at basal and during insulin infusion at medium (40) and high (400 mU/min/m2) infusion rates during the isoglycemic clamp. Maximal oxygen uptake (VO2max) was measured (Quark CPET, COSMED, Italy) before and after the intervention. Results are mean ± SD. Two-way ANOVA and paired t-test was used for testing

RESULTS: T2D and CON improved their VO2max significantly after the intervention (2.8±0.7 to 3.6±0.9 L/min (p=0.003) and 3.2±0.5 to 3.7±0.4 L/min (p=0.04), respectively). Basal RER did not change with training (0.85±0.10 and 0.83±0.04 (before) to 0.81±0.04 and 0.83±0.05 (after) in T2D and CON, respectively) and was similar in T2D and CON. RER did not increase significantly with medium insulin infusion rate compared to basal state before or after training (p=0.95 and p=0.89, in T2D and CON, respectively (data not shown)). However, in both groups, RER increased significantly with the high insulin infusion rate (T2D: 0.85±0.10 to 0.99±0.12 (before T) 0.81±0.04 to 0.98±0.07 (after T) (p=0.0001); CON: 0.83±0.04 to 0.92 ±0.05 (before T) and 0.83±0.05 to 0.92±0.06 (after T) (p<0.0001)) compared to the basal state. The increase in RER with high insulin was significantly higher in T2D compared with CON (p=0.023). However, training did not change deltaRER in T2D (p=0.62) or CON (p=0.79).

CONCLUSION: Preliminary results showed no effect of training on metabolic flexibility in neither T2D nor CON. However, our results showed that deltaRER in T2D was significantly higher compared to CON, indicating that the T2D patients are metabolic flexible. This is at variance with other studies and is explained by eu- vs. isoglycemic clamping.

ERGOGENIC EFFECTS OF INVASIVE AND NON-INVASIVE SPINAL CORD STIMULATION STRATEGIES FOLLOWING SPINAL CORD INJURY: A CASE-SERIES

HODGKISS, D.D.1, SHACKLETON, C.S.2, WILLIAMS, A.M.M.2, SAMEJIMA, S.2, BALTHAZAAR, S.J.T.1,2, LAM, T.2, KRASSIOUKOV, A.V.2, NIGHTINGALE, T.E.1,2

1 UNIVERSITY OF BIRMINGHAM, UK; 2 INTERNATIONAL COLLABORATION ON REPAIR DISCOVERIES AND UNIVERSITY OF BRITISH COLUMBIA, VANCOUVER, CANADA

INTRODUCTION: Individuals with a cervical or upper-thoracic spinal cord injury (SCI ≥T6) typically exhibit impaired exercise responses due to disrupted supraspinal sympathetic control of the cardiovascular (CV) system, which results in reduced peak heart rate (HR), low blood pressure (BP), reduced venous return and thus stroke volume (SV). Epidural spinal cord stimulation (ESCS) has demonstrated an improvement in CV control, with a subsequent increase in aerobic capacity. How-

ever, this surgical procedure is expensive and invasive. This study compared the effects of ESCS and transcutaneous spinal cord stimulation (TSCS) (an affordable, non-invasive alternative strategy) on modulating CV control and submaximal upper-body exercise performance [time to fatigue (TTF)] in individuals with SCI.

METHODS: Participants had a chronic (>1yr), motor-complete SCI. Two had an implanted epidural stimulator [P1 (59 yrs, T4 injury); P2 (24 yrs, C6 injury)], and two without an implant received TSCS [P3 (54 yrs, T4 injury); P4 (40 yrs, T4 injury)]. A mapping session was conducted to manipulate specific stimulation parameters (frequency, intensity, epidural electrode configuration, transcutaneous electrode locations in the lumbosacral region) until an optimal, sustained elevation in BP was elicited (CV-SCS). A sham condition (SHAM-SCS) was included as a comparison. A graded arm-crank ergometry exercise test identified peak oxygen uptake (VO2peak) and ventilatory threshold (VT). Following a familiarisation trial, participants exercised to fatigue at a fixed workload corresponding to above their VT on two separate occasions (>3 days recovery), with CV-SCS or SHAM-SCS. HR and gas exchange variables were recorded throughout. BP was monitored before (pre-post applying stimulation) and immediately post-exercise. Rating of perceived exertion (RPE) was determined every 5 min.

RESULTS: CV-SCS increased TTF with both ESCS [P1 (Δ11min 47s); P2 (Δ19min 11s)] and TSCS [P3 (Δ16min 28s); P4 (Δ17min 49s)], relative to SHAM-SCS. Relative to baseline, change in systolic BP at rest was greater with the application of CV-SCS in comparison to SHAM-SCS with ESCS [P1 (Δ11 vs 2 mmHg); P2 (Δ12 vs -1 mmHg)] and TSCS [P3 (Δ17 vs 4 mmHg); P4 (Δ24 vs 13 mmHg)]. Peak oxygen pulse, a reasonable surrogate for SV, was greater with CV-SCS in ESCS [P1 (Δ1.7 mL/beat); P2 (Δ2.4 mL/beat)] and TSCS [P3 (Δ0.8 mL/beat); P4 (Δ2.5 mL/beat)], relative to SHAM-SCS. RPE also tended to be lower with CV-SCS than SHAM-SCS at each corresponding timepoint during the trials.

CONCLUSION: This case-series demonstrates that both ESCS and TSCS improve submaximal upper-body exercise performance, determined via TTF, in individuals with SCI. CV-SCS modulated BP and peak oxygen pulse by seemingly increasing supraspinal sympathetic output to the vasculature to improve exercise performance. While further research is necessary, these data suggest TSCS is as effective as ESCS as an ergogenic aid and could be used to support exercise rehabilitation in this population.

FEASIBILITY OF INTEGRATING AN EXERCISE SPECIALIST SUPPORTED BY MHEALTH TECHNOLOGY TO INCREASE EXERCISE AND PHYSICAL ACTIVITY IN AN ADOLESCENT COMPLICATIONS FROM EXCESS WEIGHT SERVICE: MOTIVATE-CEW

DAVIES, A.P., HESKETH, K.L., CLARKE, E., APPERLEY, L.J., SPRUNG, V.S., JONES, H., KINNAFICK, F.E., SENNIAPPAN, S., COCKS, M.

LIVERPOOL JOHN MOORES UNIVERSITY

INTRODUCTION: To address the increasing prevalence of complications associated with severe childhood obesity, NHS England has established 21 Complications of Excess Weight (CEW) services. Despite physical activity (PA) and exercise forming cornerstones of successful weight management programmes, CEW services may not have the capacity to include specialists in their delivery. We propose the inclusion of mHealth (mobile health) technologies could assist specialists with the prescription and long-term monitoring of PA and exercise in CEW services. The aim of the study was to assess the feasibility of embedding an exercise specialist led, mHealth supported, PA and exercise intervention (MOTIVATE-CEW) to a CEW service.

METHODS: A 12-week feasibility, parallel group, randomised control trial was conducted in 23 adolescents with obesity (m/f n=10/13, age 15±1y, SDS BMI 3.54±0.54) receiving care from the Alder Hey Children's Hospital (AHCH) CEW service. Participants were randomised to usual care (UC, n=11) or UC plus MOTIVATE-CEW (n=12). UC involved the development of an individualised care plan with a multidisciplinary team. Participants receiving MOTIVATE-CEW co-designed a personalised and progressive exercise and PA programme alongside an exercise specialist. The intervention was facilitated by mHealth technologies (smart watch, mobile app and coach's platform) which enabled remote exercise sessions and feedback to be guided by biometrics. A mixed method process evaluation assessed reach, dose and fidelity, and preliminary effectiveness was measured (health related quality of life (HRQOL), body composition and cardiovascular disease risk factors).

RESULTS: 45% of eligible participants were recruited and 87% completed post-intervention assessments. Recruited participants shared similar demographics to the AHCH CEW service cohort in terms of age, sex, and deprivation. Large effect sizes favouring MOTIVATE-CEW were observed for the number of exercise sessions completed per week (MOTIVATE-CEW 2±2, UC 0±0; d=1.02) and time spent completing moderate-to-vigorous intensity exercise per week (MOTIVATE-CEW 97±127 mins, UC 5±12 mins; d= 1.01), captured through an optical heart rate monitor. Qualitative perceptions of MOTIVATE-CEW were positive, key facilitators included regular personalised advice from an exercise specialist and the creation of graded action plans with specific behavioural goals. Data availability for in-clinic outcomes was good (≥85%). Preliminary evidence of moderate-to-large effects in favour of MOTIVATE-CEW were observed for HRQOL (EQ-5D-Y visual analogue scale score; d=0.80), HDL cholesterol (d=0.67) and triglycerides (d=0.62).

CONCLUSION: The MOTIVATE-CEW intervention demonstrated positive effects on exercise behaviour, suggesting that the addition of exercise specialists supported by mHealth technologies to CEW services would be an effective strategy to improve engagement in exercise and PA. Good reach and data availability suggests this study design is feasible for future trials.

EVALUATING A SPORT AND EXERCISE INTERVENTION ON METABOLIC SYNDROME, PAIN, COGNITIVE FUNCTION AND CARDIORESPIRATORY FITNESS AMONG FORCIBLY DISPLACED ADULTS. A RANDOMIZED CONTROLLED TRIAL

KNAPPE, F., FILIPPOU, K., HATZIGEORGIADIS, A., MORRES, I.D., GERBER, M.

UNIVERSITY OF BASEL

INTRODUCTION: Global challenges such as armed conflict or natural disasters have forced many people to leave their homes and led to a doubling of displacements in the past ten years [1]. Those affected face severe physical strain before, during, and after their flight. Unsurprisingly, an increased risk for physical health complaints among forcibly displaced adults has been reported compared to the general population [2]. These challenges can further result in functional restrictions that affect the individuals well-being and pose a barrier for social integration [3]. The present study aimed to examine the effects of a sport and exercise intervention on metabolic syndrome, pain, cognitive function, and cardiorespiratory fitness.

METHODS: One-hundred and forty-two adults (75 women, mean age = 29.2) living in a refugee camp in Greece were randomly assigned by housing units to an intervention (n=74) and a wait-list control group (n=68). Sport and exercise activities (e.g., ball sports, strength training) were implemented five times a week (60 minutes) over ten weeks. The intervention was co-designed with the participants to consider contextual and culturally specific conditions and interests. Metabolic syndrome risk markers (waist circumference, fasting plasma triglycerides, HDL-C, HbA1c, and blood pressure) were assessed and standardized to calculate a continuous metabolic syndrome score. Pain in different body regions (head, back, chest, abdomen, extremities) was measured using a visual analog scale. The Oddball paradigm and the Flanker task were used to assess attention and inhibition. Finally, cardiorespiratory fitness was measured with the (submaximal) Åstrand-Rhyming Test.

RESULTS: A total of ninety-two (64.8%) participants completed the post-assessment. Twenty (40.8%) individuals met the recommendation and attended two or more sessions per week. After performing ANCOVA and controlling for baseline values, we found evidence that VO2max increased more in the intervention group than in the wait-list control group after the 10-week intervention trial (B = 4.05, 95 % CI: 0.74; 7.35, p = 0.017). No statistically significant changes were found for metabolic syndrome, pain, and cognitive functions. However, in hierarchical regression, higher attendance rates predicted lower pain scores and waist circumference at post-intervention.

CONCLUSION: The study points out that regular participation in sports and exercise programs is central to the effectiveness of the intervention. Therefore, research into measures to maintain compliance is needed.

OP-SH16 Rating of perceived exertion

AN EXPLORATORY ANALYSIS OF TRIMP, RUNNING SPEED, AND SESSION RPE AS TRAINING LOAD FORMULAS IN A SAMPLE OF 596 DISTANCE RUNNERS.

MORIO, C., PETOT, H.

DECATHLON SPORTSLAB

INTRODUCTION: Training load is a crucial aspect of the training process, as it can significantly impact the runners performance and risk of injury. Notably, the TRaining IMPulse (TRIMP) formula used heart rate (HR) to estimate an athlete's internal load (1). The advent of GPS technology allowed for measuring the external load based on speed or running distance. Finally, the session RPE (sRPE) is supposed to represent the global perceived load (2). This study aims to compare the outputs of these training load formulas in running, as well as the other variables closely related like average HR, distance, and duration.

METHODS: We extracted a sample of specific training sessions from an app where runners provided their RPE after each training log. The HR and GPS data were collected by the runners' own devices. After removing outlier data (speed: [6-30]km/h, age: [18-75]years, maximal aerobic speed (MAS) : [10-25]km/h, elevation: <0.5% of average slope), the different training load formulas were computed. The internal load was estimated using the average HR (in absolute and in %HRreserve) and the TRIMP formula (1). The external load was estimated using the total duration and distance, the average speed (in absolute and in %MAS) and a TRIMP like formula (TRIMPV) with the %MAS replacing the %HRR from the original formula (3). The perceived load was expressed in both absolute RPE and sRPE (2). First, an exploratory principal component analysis (PCA) and a correlation matrix analysis were performed on the 10 training load variables. Then, general linear models were applied between TRIMP, TRIMPV and sRPE, where slope, bias, r^2 and RMSE were calculated.

RESULTS: 5486 running sessions from 440 males and 156 females (age: 40.6±8.9yo; mass: 72.1±11.1kg; Stature: 175.2±9.0cm; BMI: 23.4±2.7; MAS: 14.8±2.2 km.h-1) were analyzed.

The PCA reveals that 90% of the variance of training variables could be explained by 4 principal components which could be closely linked to duration, HR, Speed, and RPE, respectively.

As expected with such a large sample size, 39 out of 45 correlations were significant (p<.001) but only 11 presented very large effect sizes (r>.7), among those TRIMP, TRIMPV, and sRPE were correlated to each other.

The linear model between TRIMP and TRIMPV presented a slope of 0.98 and a bias of 9.4% with r2=.59. The linear model with sRPE presented a slightly higher bias 12.1% and 15.0% and lower r2 .54 and .50 with TRIMP and TRIMPV, respectively. RMSE values ranged between 37.1% and 45.3%.

CONCLUSION: The different training load formulas could be to some extent interchangeable for global usage and general comparison purpose. However, the moderate r2 and high RMSE values, associated with the PCA results confirm that these different formulas actually provide complementary information on different aspects of the running training load.

The perceived load was expressed in both absolute RPE and sRPE (2). First, an exploratory principal component analysis (PCA) and a correlation matrix analysis were performed on the 10 training load variables. Then, general linear models were applied between TRIMP, TRIMPV and sRPE, where slope, bias, r^2 and RMSE were calculated.

RESULTS: 5486 running sessions from 440 males and 156 females (age: 40.6±8.9yo; mass: 72.1±11.1kg; Stature: 175.2±9.0cm; BMI: 23.4±2.7; MAS: 14.8±2.2 km.h-1) were analyzed.

The PCA reveals that 90% of the variance of training variables could be explained by 4 principal components which could be closely linked to duration, HR, Speed, and RPE, respectively.

As expected with such a large sample size, 39 out of 45 correlations were significant (p<.001) but only 11 presented very large effect sizes (r>.7), among those TRIMP, TRIMPV, and sRPE were correlated to each other.

The linear model between TRIMP and TRIMPV presented a slope of 0.98 and a bias of 9.4% with r2=.59. The linear model with sRPE presented a slightly higher bias 12.1% and 15.0% and lower r2 .54 and .50 with TRIMP and TRIMPV, respectively. RMSE values ranged between 37.1% and 45.3%.

CONCLUSION: The different training load formulas could be to some extent interchangeable for global usage and general comparison purpose. However, the moderate r2 and high RMSE values, associated with the PCA results confirm that these different formulas actually provide complementary information on different aspects of the running training load.

CRITERION VALIDITY OF A NEW RPE SCALE TO ASSESS THE PSYCHOLOGICAL LOAD OF PHYSICAL TRAINING

NIGRO, F., MARCORA, S.M.

UNIVERSITY OF BOLOGNA

INTRODUCTION: Mellalieu et al. have proposed a theoretical framework that identifies 3 main sources of psychological load in athletes: a) training and performance, b) organization, and c) personal (1). Previous studies have proposed the use

of scales such as differential rating of perceived exertion (RPE), or the NASA-TLX questionnaire as instruments to measure the different components of workload with respect to the training session or the task performed. The purpose of this pilot study was to investigate the feasibility and criterion validity of two new RPE scales that separate the psychological load of a training session from the physical one.

METHODS: 53 athletes from a variety of sports were recruited for this study. Participants filled out a questionnaire and 5 unidimensional scales 30 minutes after one of their regular physical training sessions. The questionnaire consisted of some questions about personal details, practiced sport, training experience, and the content of the training just performed. After completing the questionnaire, participants rated how hard the training session was overall using the RPE CR10 scale modified by Foster (2) (O-RPE). Afterwards, participants rated their training according to the following four scales presented in random order: the physical demands and the mental demands subscales of the NASA-TLX questionnaire (criterion measures), and 2 differentiated ratings (physical and mental) of the RPE CR10 scale modified by Foster (2). For the Physical-RPE, participants were asked to rate the muscular and/or respiratory effort required by the training session. For the Mental-RPE, participants rated how demanding the training session was in terms of attention, concentration, learning. memory, emotion and motivation required by the training session. An exploratory analysis was conducted using Spearmans rank correlation test.

RESULTS: The Mental-RPE scores were highly correlated with the NASA mental demand scores (rho=0.80,p<0.001) whilst the Physical-RPE scores were highly correlated with the NASA physical demand scores (rho=0.83,p<0.001). There was also a significant correlation between the Mental-RPE scores and the Physical-RPE scores (rho=0.75,p<0.001). All the NASA and differentiated RPE scores correlated significantly with the O-RPE scores (rho=0.75-0.87,p<0.001).

CONCLUSION: The new differentiated RPE scales were feasible within a field setting. The high correlations with the NASA scales provide preliminary evidence of criterion validity of both the Mental-RPE and the Physical-RPE scales. Because hard physical training can pose significant psychological demands, the high correlation between the Mental-RPE scores and the Physical-RPE scores may be expected. Therefore, further research is required to assess the discriminant validity of these two new scales in the context of training with more varied demands (e.g. physical vs technical/tactical training sessions).

A META-ANALYSIS OF THE CRITERION-RELATED VALIDITY OF SESSION-RPE SCALES IN ADOLESCENT ATHLETES

LIU, H.C.1, YANG, W.1, LI, Q.1, BAO, D.2, LIU, H.Y.1, HO, I.3,4

1 BEIJING SPORT UNIVERSITY 2 BEIJING SPORT UNIVERSITY 3 HONG KONG METROPOLITAN UNIVERSITY 4 ASIAN ACADEMY FOR SPORTS AND FITNESS PROFESSIONALS

INTRODUCTION: Progressively increasing the training load (TL) is one of the keys to improving athletic performance. Due to the close association between excessively high training volumes and the occurrence of injuries among youth athletes, TL monitoring is particularly pertinent. s-RPE is a more straightforward, non-invasive, and inexpensive method for TL monitoring meanwhile it can monitor the internal load. As this approach has been used and validated in a wide variety of sports and strength and conditioning programs for adults, there may be some limitations when applied to children and adolescents. The objective of this study was to establish the criterion-related validity of the s-RPE method in adolescent athletes.

METHODS: According to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA 2020) guidelines, a meta-analysis (PROSPERO ID: CRD42022373126) was performed. Eight databases using the following terms: ('s-RPE' OR 'Rating Perceived Exertion session' OR 'RPE session' OR 'RPE' OR 'Rate of Perceived Exertion' OR 'Rated of Perceived Exertion') AND ('Adolescen*' OR 'Youth*' OR 'Teen*') AND ('validity' OR 'correlation' OR 'concurrent validity') were searched up to 2022. Articles meeting the inclusion criteria were screened and adopted the "Methodological Index for Non-Randomized Studies (MINORS)" to evaluate the risk of bias. The certainty of evidence was rated using the GRADE PRO. The relationships between s-RPE and TRIMP were computed using correlation coefficient (r values) and Fishers r-to-z. A 95% confidence interval (95% CI) was reported and the significance level was set at $p<0.05$.

RESULTS: An initial 1798 studies using the s-RPE method were identified and finally, a total of 16 studies were included for further analysis. The exercise modality included 7 team sports and 4 individual sports. The bias scores indicated that all studies were classified as having a low risk of bias. GRADE Pro approach suggested that the authors are highly confident in the association. A total of 15 studies evaluated the correlation between CR-10 and heart rate, involving 170 athletes, while a total of 3 studies evaluated the correlation between CR-100 and HR, involving 108 athletes. A strong to very strong correlation between s-RPE and HR was observed (overall: r=0.74; CR-10: r=0.69; CR-100: r=0.80). CR-100 scale (Fisher's z=1.09) was shown to have a higher criterion validity than that of the CR-10 scale (Fisher's z=0.85).

CONCLUSION: Preliminary findings showed that s-RPE using either CR-10 or CR-100 scales can be valid tools for monitoring internal training load for children and adolescent athletes. Considering the superior benefits of s-RPE and high criterion validity with HR measures, coaches can use it as a "stand-alone" tool for global internal TL monitoring. Future studies should focus on whether CR-100 could better perform than CR-10 for junior and children athletes in different age groups and sports as well as the causes leading to potential scoring biases.

OP-AP34 Football: Sleep

IS AEROBIC PERFORMANCE AFFECTED BY SLEEP AND CHRONOTYPE IN YOUNG SOCCER PLAYERS?

CIORCIARI, A.1, MULÈ, A.1, CASTELLI, L.1, GALASSO, L.1, ESPOSITO, F.1,2, ROVEDA, E.1,2, MONTARULI, A.1,2

1UNIVERSITY OF MILAN, 2IRCCS ISTITUTO ORTOPEDICO GALEAZZI

INTRODUCTION: The phenotypic expression of circadian rhythms can be defined as Chronotype (CT). People can be classified into three major typologies: Morning-type (M-type), Neither-type (N-type) and Evening-type (E-type). M-types tend to perform better in the morning, while E-types in the evening (Ayala 2017). This difference seems closely correlated to the diverse sleep pattern of the 3 CTs. It has been observed that bad sleep habits tend to worsen physical performance, expecially in endurance and prolonged exercises (Fullagar 2015). Although a substantial body of literature has explored the relationship between sleep, chronotype and physical exercise, it is still unclear the impact that such chronobiological variables have on specific sports, populations and types of performance. Therefore, in this study we wanted to assess the agility, strength and endurance in young soccer players in relation to their sleep quality and chronotype.

METHODS: 58 young male soccer players, aged between 13 and 19 years, were recruited from a non-professional team. They were asked to compile the Morningness - Eveningness Questionnaire (MEQ) and the Mini-Sleep Questionnaire (MSQ), to assess respectively the CT and sleep quality. The physical trial was performed in the morning, at 8:30 AM, and in the evening, at 6:00 PM. Both sessions included three tests to determine agility, carried out by the Illinois Agility Test, strength, assessed by the Sargent Jump Test, and endurance, estimated by the 6 Minutes Run Test (6MRT).

RESULTS: The total sample (n = 58; age = 15.16 ± 1.73; BMI = 20.61 ± 2.24) was classified by CT as M-types (n = 11), N-types (n = 29) and E-types (n = 18). Furthermore, the subjects were categorized as Good Sleepers (GS, n = 28) and Bad Sleepers (BS, n = 30).

The repeated measures ANOVA showed a statistically significant difference in the comparison between the 3 CTs in the 6MRT ($p < 0.001$): M-types performed better in the morning ($p = 0.01$), while E-types in the evening ($p < 0.001$). Paired t-test reported that GS performed better than BS ($p = 0.019$) in the 6MRT in the PM session.

CONCLUSION: As regards the effect of CT on physical performance, the results of the present study underline the difference in aerobic power between M- and E-types during the morning and evening session. Furthermore, BS performed worse than GS in the PM session of the 6MRT. Our findings fit well with the actual literature on soccer player performance and sleep, as our data showed a significant effect of sleep on aerobic power, but not on strength and agility. Aerobic performance in soccer player can be crucial, and the small differences displayed by this study can separate success and defeat.

SLEEP DURING A TRAINING CAMP IN ELITE ADULT FEMALE SOCCER PLAYERS

COSTA, J.A.1, CARDOSO, V.1, REIS, C.2, TOMÁS, R.1, CAVACA, M.1, BRITO, J.1

1PORTUGAL FOOTBALL SCHOOL, PORTUGUESE FOOTBALL FEDERATION, 2CATÓLICA RESEARCH CENTRE FOR PSYCHOLOGICAL - FAMILY AND SOCIAL WELLBEING, UNIVERSIDADE CATÓLICA PORTUGUESA, LISBON, PORTUGAL

INTRODUCTION: In recent years, the growing interest in understanding how athletes sleep has boosted the number of scientific studies on the topic.1 Elite athletes, including female soccer players, often spend nights in unfamiliar hotel environments, before home and away matches, and during training camps that may affect sleep habits.2 In this scenario, optimizing recovery through sleep is required to reduce the risk of transitioning into a state of excessive fatigue as well as to reduce the risk of injuries.1 Thus, this study aimed to describe sleep characteristics in elite adult female soccer players during a training camp for a National team.

METHODS: Twenty-five elite adult female soccer players (aged 25.4 ± 2.3 years; mean ± SD) participated in the study. Sleep variables were measured using wrist actigraphy and sleep diaries during eight consecutive days (i.e., 6-days with training sessions, and 2-days with matches). Salivary melatonin and cortisol were also measured to access objective sleepiness and alertness on the second and third days of the training camp. Training and match loads were characterized using a global positioning system.

RESULTS: During the eight nights, 8 to 25 players slept less than <8 h, and 10 to 25 players had a sleep efficiency of < 80% in two or more days of the training camp. No significant differences ($p<0.05$) were found between days with training sessions vs. matches for sleep duration (mean [minimum; maximum], 7.9 [5.3;9.2] vs. 7.9 [4.9;10.1] hours, respectively) and sleep efficiency (87 [60;98] vs. 88 [71;98] %, respectively). Self-rate sleep quality (0 "bad" to 10 "excellent") was 7 (1;10) arbitrary units (median [minimum; maximum]). Mid-point of unrestricted sleep was 4.1 (2.3;5.3) hours (i.e., 1 player has characterized as slightly early; 18 players as intermediate, and 6 players as slightly late chronotype). Salivary melatonin measured before sleep was 15 (1.1;332.9) pg/mL, and cortisol measured upon awakening was 15 (6.1;24.9) ng/mL, throughout the second and third days of the training camp. Salivary melatonin and cortisol amplitude were 58.2 (8.3;486.1) pg/mL

and 15 (4.7;23.4) ng/mL, respectively, throughout the second and third days of the training camp. Individually, exposure time, total distance covered, and high-speed running (15.6–23km.h-1) during training sessions were 64 (55;76) min, 3749 (1141;6358) m, and 81 (11;151) m, respectively. During matches, exposure time, total distance, and high-speed running were 59 (20;98) min, 5948 (2008;9887) m, and 512 (72;953) m, respectively.

CONCLUSION: Overall, this study highlights the individual variability of sleep associated parameters, indicating the importance to monitor sleep in elite adult female soccer players during a training camp. Considering this scenario, individualized recovery and monitoring strategies may be required to ensure that all players are in peak condition for training and competition.

HOW MUCH SLEEP DOES A FOOTBALL PLAYER NEED?

FIGUEIREDO, P.1,2,3, MARQUES, E.A.2,4, CUNHA, L.2, NASSIS, G.1, COSTA, J.A.3, LASTELLA, M.5, BRITO, J.3

1: UNITED ARAB EMIRATES UNIVERSITY, UAE; 2: CIDESD, PORTUGAL; 3: PFS-FPF, PORTUGAL; 4: LOUGHBOROUGH UNIVERSITY, UK; 5: CENTRAL QUEENSLAND UNIVERSITY, AUSTRALIA

INTRODUCTION: Sleep is recognised as an essential component to athletic performance and recovery. Yet, compared to general recommendations, and their self-reported sleep needs, athletes typically obtain less than the recommended, which can negatively impact performance, recovery, and health. Previous data have examined sleep needs across multiple sports (1); however, little is known about football players sleep requirements.

Therefore, this study compared football players self-assessed sleep needs and habitual sleep duration and the association of sleep insufficiency with their sleep habits.

METHODS: The study included 305 adult football players (53 females, 137 from national leagues, 63 professionals, mean age = 23.6 yrs). The players answered the question, "how many hours of sleep do you need to feel rested?". For each player, a sleep deficit index was calculated by subtracting sleep duration from individual self-assessed sleep needs. A difference of 1h or more indicated insufficient sleep (1). Sleep quality was measured using the Pittsburgh Sleep Quality Index (PSQI) (2), daytime sleepiness with the Epworth Sleepiness Score (ESS) (3), and diurnal type with the Morningness-Eveningness questionnaire (4). Differences between sleep need and habitual sleep duration were analyzed with a linear mixed model. Logistic regression analyses were used to estimate odds ratios (OR) and 95% confidence limits (CL) for insufficient sleep.

RESULTS: Players reported an average subjective sleep need of 8.1 (5-10) hours and an average sleep duration of 7.4 (4.5-10) hours ($p<0.001$). The prevalence of insufficient sleep for the total sample was 47.9%. When stratified by the sleep/wake variables, the prevalence of insufficient sleep was 68.7% for the poor sleepers, 52.3% for players with excessive daytime sleepiness, and 53.4% for the evening type chronotype. When stratified by professional status, the prevalence of insufficient sleep was 52.5% for non-professionals and 30.2% for professionals. The associated factors with the risk of insufficient sleep were sleep quality (poor sleep: OR 4.90, 95% CL 3.29-7.39), daytime sleepiness (excessive: OR 4.85, 95% CL 2.78-9.00), diurnal type (evening type: OR 3.99, 95% CL 2.30-7.05) and the professional status (professional: OR 0.43, 95% CL 0.24-0.74).

CONCLUSION: Adult football players need, on average, 8.1 hours of sleep to feel rested. However, a large proportion of players (47.9%) failed to meet individual sleep needs on most nights. Athletes with low sleep quality, excessive daytime sleepiness, evening type chronotype, and who are non-professional seem to be at a higher risk of insufficient sleep, which may negatively impact performance, recovery, and health.

EVENING WHEY PROTEIN INTAKE, RICH IN TRYPTOPHAN, AND SLEEP IN ELITE MALE AUSTRALIAN RULES FOOTBALL PLAYERS

CONDO, D., FERGUSON, C., LASTELLA, M., ROBERS, S., AISBETT, B.

DEAKIN UNIVERSITY

INTRODUCTION: Fundamental to athlete recovery and performance is sleep (1). Protein intake has been shown as a potential strategy to influence sleep (2, 3), including in Australian Football League (AFL) players (4). An important factor in the protein-sleep relationship may be the type and timing of ingestion, with evidence indicating that protein high in the amino acid tryptophan consumed 2-4 hours before sleep may improve sleep outcomes (5, 6). However, it remains unclear

whether these practices can improve sleep in athletic populations. The primary aim of this study was to investigate the effect of evening whey protein supplementation, rich in tryptophan on sleep in elite male AFL players.

METHODS: A double-blinded, counterbalanced, randomised, cross-over study examined whether a whey protein supplement, rich in tryptophan, would improve sleep in 15 elite male AFL players on training and non-training days during pre-season. A 5-day pre-intervention period determined habitual dietary intake and baseline sleep measures, used to standardise dietary intake and timing of the supplement or placebo during the intervention. Dietary intake was assessed using a smartphone application (Easy Diet Diary). Sleep/wake behaviour was assessed using a wrist activity monitor (Actical) and sleep diary. Players were provided with either the whey protein supplement or placebo drink on each intervention day and instructed to consume the drink 3h prior to their habitual bedtime. The drinks were isocaloric and matched for taste and colour. All evening meals were provided in accordance with individual habitual intake and remained consistent between the interventions. Separate one-way repeated measures analysis of covariance for training and non-training days were used to analyse any differences between the whey protein supplement and placebo for sleep duration, sleep efficiency (SE), wake after sleep onset (WASO), sleep onset latency (SOL).

RESULTS: The habitual sleep/wake behaviour during the 5-day pre-intervention period for bedtime, SOL, WASO, SE, wake up time and sleep duration on training days was 23:18 ± 1:12 (hh:mm), 18.8 ± 10.0min, 52.6 ± 31min, 90.0 ± 5.6%, 08:36 ± 01:18 (hh:mm), and 7.9 ± 1.1h, respectively and on non-training days was 22:54 ± 1:06 (hh:mm), 20.8 ± 13.1min, 49.5 ± 23.6min, 89.7 ± 4.3%, 07:18 ± 00:30 (hh:mm), and 7.1 ± 0.8h, respectively. No differences were observed for all sleep outcomes between consumption of the whey protein supplement and placebo on training and non-training days ($p>0.05$).

CONCLUSION: The consumption of a whey protein supplement, rich in tryptophan did not improve sleep outcomes in elite male AFL players. However, athletes may be able to ingest a high protein /energy intake close to bedtime without impairing sleep, an important finding for athlete recovery. It is unknown whether this intervention could be valuable for athletes with poor sleep, during periods of restricted sleep or for those athletes with a low habitual protein intake, requiring further investigation.

SLEEP PATTERNS OF ELITE FEMALE FOOTBALL MATCH OFFICIALS DURING WEURO2022: IMPACT OF PROXIMITY TO MATCH DAY, KICK-OFF TIME AND ROLE ON MATCH DAY

TARNOWSKI, C.A.1, HELSEN, W.F.2, QAQAYA, N.Y.2, ROLLO, I.R.1

1 GATORADE SPORTS SCIENCE INSTITUTE, PEPSICO R&D LIFE SCIENCES, UK, 2 UNION OF EUROPEAN FOOTBALL ASSOCIATIONS , SWITZERLAND

INTRODUCTION: Sleep has numerous important physiological and cognitive restorative functions that are particularly important to elite sports performers and, therefore, also to elite match officials. Athletes are advised to achieve sufficient sleep duration (> 7 hours) and quality (>85%) per night. Elite athletes are reported to have poorer quantity and quality of sleep in comparison to the general population. However, there is currently no research into the sleep habits of elite football match officials who are exposed to similar physical and perceptual-cognitive demands. Therefore, the aim of this study was to examine the impact of proximity to match day (MD), kick-off (KO) time and role on MD on sleep patterns of elite female match officials during the 2022 UEFA European Womens Football Championship (WEURO 2022).

METHODS: Sleep was measured over 18 ± 5 days in nine elite female football match officials (age: 39 ± 4 y) during a 25-day international tournament (WEURO 2022). Wrist-worn actigraphy (Biostrap EVO, USA) was used to measure night-time sleep duration (h:min), sleep onset and wake time (h:min), and sleep efficiency (%; percentage of time in bed spent asleep). Data was analysed by proximity to MD: Training Day (TD; pitch/gym based, at least +/-2 days from MD), MD-1, MD and MD+1; KO time: 17:00 PM or 20:00 PM; and, Role on MD: Referee or Fourth Official. Data are shown as mean ± SD (range), with statistical significance set at $p < 0.05$.

RESULTS: Sleep duration was 7:20 ± 1:20 (6:20 – 8:04), with no difference between type of day (MD: 6:46 ± 1:38, TD: 7:25 ± 1:16, MD-1: 7:37 ± 1:18 and MD+1: 7:12 ± 1:12, $p > 0.05$). Total time in bed was lower on MD (7:22 ± 1:29) compared to MD-1 (8:25 ± 1:19) and TD (8:15 ± 1:07, $p < 0.05$). Sleep onset time was later on MD (00:54 ± 1:22) compared to MD-1, MD+1 and TD (23:39 ± 1:07, 23:58 ± 0:52 and 23:27 ± 0:52, $p < 0.01$) and sleep wake time was later on MD (8:06 ± 0:58) compared to TD (7:42 ± 0:48, $p < 0.05$). An 20:00 PM KO resulted in later sleep onset time (01:29 ± 01:04) compared to 17:00 PM KO (00:00 ± 1:21, $p < 0.01$), with no differences observed in sleep wake time ($p > 0.05$). Accordingly, sleep duration was shorter after 20:00 PM KO compared to 17:00 PM KO (6:00 ± 1:05 vs. 8:06 ± 1:38, $p < 0.01$), as well as total time in bed (6:44 ± 0:59 vs. 8:22 ± 1:38, $p < 0.01$). No differences were observed in any variables between Referee and Fourth Official performance ($p > 0.05$). Sleep efficiency was 89 ± 7% (81-96%) throughout the tournament with no differences observed between type of day, KO time or role on MD ($p > 0.05$).

CONCLUSION: Elite female football match officials, on average, achieved the recommended sleep duration and quality during WEURO 2022, however there was large interindividual variation. Sleep duration was <7 h on MD and after 20:00 PM KO, likely due to a later sleep initiation and non-compensatory wake time. As such, individualized sleep hygiene strategies which consider match scheduling are recommended.

LEGACIES OF THE 2022 COMMONWEALTH GAMES FOR BIRMINGHAM COMMUNITIES AND INDIVIDUALS FROM DISADVANTAGED BACKGROUNDS: EVIDENCE FROM THE QUALITATIVE DATA

HEYES, A., ALHARBI, A., CARTER, B., KARAMANI, M., LEE, M., LIANG, X., QUINTON, M., VAN ZANTEN, J.V., CHEN, S.
UNIVERSITY OF BIRMINGHAM

Introduction

Major and mega sporting events have transformative power to the host city and countries but they are expensive to stage. Politicians and event organisers justify such costs with headline claims that major-event-hosting can generate economic, social, and environmental legacies for the host region. However, event hosting does not always benefit everyone. For cities such as Birmingham (United Kingdom), with 90% of wards being more deprived than the national average, the hosting of the 2022 Commonwealth Games (CWG) attracted substantial media scrutiny, particularly given that a key mission was to deliver 'A Games for Everyone'. As part of a larger study, this cross-disciplinary research explored the legacies of the CWG for communities and individuals from disadvantaged backgrounds (CIDBs) in Birmingham.

Methods

Seven pre-Games (one-month prior to the Games) focus groups were conducted (N = 37) with CIDBs across Birmingham. Guided by event legacy literature and social exchange theory, example questions included: What are individuals attitudes and perceptions of the CWG? What legacies do people anticipate from the Games and how? Data were coded and analysed through reflexive thematic analysis.

Results

There were five themes generated from the pre-Games data: (1) varied attitudes towards the Games, (2) a divided expected legacy, (3) the Commonwealth Games magnifies inequality, (4) barriers resulting in limited engagement, and (5) the importance of community. The findings revealed that individuals, community groups, or community leaders perceived that they were not included in the planning of the events and legacies. Initial communication with the Commonwealth Games organising committee was not sustained or meaningful. Promises of a Games sold for its equality, diversity, and inclusion was perceived as superficial and tokenistic. Participants experienced difficulties taking part in the Games (e.g., volunteering, watching events), felt excluded by the events, had limited awareness of legacy opportunities, and identified a lack of training (i.e., skills development) to ensure equal opportunities in accessing the events. The importance of community was reiterated throughout with a belief that community groups and champions could help to leverage the Games legacy but also act as a bridge between the event and host communities.

Discussion

To our knowledge, this is the first study to explore the views of the legacies of a mega-sporting event of CIDBs. The pre-Games results identified an inclusion problem that CIDBs were not viewed as an integral part of the Games. Moreover, due to the lack of financial and resource support, though there were benefits and opportunities associated with the Games, CIDBs struggled to capitalise on them. Future mega sporting events must ensure CIDBs are better consulted and engaged throughout the event hosting process.

BETTER BASKETBALL ORGANIZATION BETWEEN TWO DIFFERENT CULTURES: THE CHINESE AND THE SPANISH

WANG, J.F.
TECHNICAL UNIVERSITY OF MADRID

Introduction

This research focuses on China and Spain and compares how basketball is managed and developed in these states by focusing on cultural differences between the countries. The aim is to identify notable differences in how basketball growth is approached between two different cultures.

Methods

This study used a mixed-methodologies approach to data collecting, including both qualitative and quantitative methods. Analysis of the responses via Atlas.ti software and a review of scientific literature helped identify a few significant differences regarding training approaches, assessment of coaches, government support, regional development, and talent acquisition. Triangulation was used to combine data from twenty semi-structured interviews, ten representatives from the Chinese Basketball Association (CBA) and ten officials of the Spanish Basketball Federation (FEB), and a study of relevant literature. The literature review was integrated into the methodology to provide a broader understanding of the cultural differences between Spain and China and how they may impact the development and management of basketball. In particular, the study was issued by the Ethics Committee of the Technical University of Madrid, which demonstrates that the study meets the ethical requirements.

Results

The comments of the interviewees indicated that the Spanish Basketball Federation (FEB) and the Chinese Basketball Association (CBA) approach athlete training, coach evaluation, government assistance, regional development, and talent acquisition in different ways. Basketball was discovered to be more professionalized and centralized in Spain, with a major emphasis on player development and conditioning. Basketball in China, on the other hand, was discovered to be more community-based, with a focus on grassroots promotion. The statistics also revealed considerable discrepancies in each countrys amount of investment and resources dedicated to basketball, with China investing more in infrastructure and facilities to promote the sports development. Furthermore, the study indicated disparities in the coaching styles and training methods employed in the two nations, with China emphasizing physical training and conditioning and Spain emphasizing technical and tactical training.

Discussion

The findings demonstrate that the individualistic culture of Spain implies peculiarities that contribute to the better development of basketball. Overall, the findings suggested that cultural differences have a substantial impact on how basketball is handled and developed in these two nations. Thus, while basketball has a strong culture in both Spain and China, the sport is governed and promoted differently in each nation due to cultural differences such as history, customs, and government interests. This result can be a recommendation for other nations to promote basketball growth.

LEVERAGING THE 2023 FIFA WOMEN'S WORLD CUP FOR SUSTAINABLE FAN ENGAGEMENT – A PRELIMINARY ANALYSIS

CUTRUPI, C.

UNIVERSITY OF TECHNOLOGY SYDNEY

The substantial long-term growth experienced by women's football globally has recently resulted in a familiar phase of stagnation, as attendance numbers struggle to remain consistently high and broadcast demands not being met (Meier, 2020). This has also been evident in Australia where the women's national team, the Matildas thrives while the semi-professional A League Women has struggled to grow in regards to game attendance and spectator engagement (Football Federation Australia, 2019). In this presentation, we investigate how the leveraging of a sport mega event – the 2023 FIFA Women's World Cup – can contribute to sustainable fan engagement of women's football in Australia.

The hosting of the FIFA WWC 2023 in Australia and New Zealand in July/August 2023 presents a significant opportunity for Football Australia and its stakeholders to advance women's sport into a position that ensures a prosperous and sustainable future. However, while we know about the leveraging intentions of event organisers to achieve economic and socially driven outcomes (Chalip & Leyns, 2002; Chalip, 2004; Chalip, 2006; D'Hoore et al., 2022) – and how significant fans are to value growth (Kolyperas & Maglaras, 2018; Allison, 2013) – we know very little about sport organisations and how they view leveraging events as a tool to achieve sustainable fan engagement (Smith, 2014; Schulenkorf et al., 2016; Singleton, 2017) – especially in women's sport. Moreover, existing literature has indicated that much of the research conducted within the fan engagement space has primarily focused on men's sporting teams and events, with limited data available on women's sporting leagues (Toffoletti, 2017; Delia, 2020; Clarke et al., 2022). Taken together, there is a lamentable gap in the space of event leverage and sustainable growth in women's sport that deserves to be examined from an organisational perspective (see Sant, 2015; Wasser et al., 2022; Dionisio et al., 2022).

In this presentation, we offer preliminary findings from a larger research study on event leverage for sustainable fan engagement around the WWC 2023. Specifically, we look back at previous sport event leverage attempts and assess key strategies that have been successfully implemented by sporting organisations in their respective leveraging efforts. Moreover, we provide structured social media data that we collected in the lead-up to the event and discuss how social media can be used as a tool to maximise event-related opportunities. In doing so, we make two critical contributions across practice and theory. First, we illicit a number of socio-managerial strategies for event organisers and sport organisations to use in their leveraging efforts; and second, we propose a new event leverage framework that goes beyond current conceptualisations by focusing specifically on (sustainable) fan engagement as a core outcome.

THE PERCEPTION OF OLYMPIC AGENDA 2020 RECOMMENDATIONS OF COLLEGE STUDENT ATHLETES IN TAIWAN: A CROSS-SECTIONAL STUDY ON THE IMPLEMENTATION OF THE AGENDA IN 2021

YANG, Y.J.

NAIONAL PINTONG UNIVERSITY OF SCIENCE AND TECHNOLOGY

Introduction

In December 2014, the International Olympic Committee (IOC) has officially approved the Olympic Agenda 2020 at the 127th IOC Session. The strategic roadmap, consisting of 40 recommendations, was built on the three pillars of Credibility, Sustainability and Youth. Since the release of the document, it served as a guide for countries around the globe to commit to reform, promote and implement accordingly. Six years after the adoption of the Agenda at the 137th IOC Session on the 10th of March 2021, the Executive Board agreed the closing report of this Olympic Agenda 2020 unanimously. Hence, it is also of great importance to understand how college student athletes in Taiwan perceive the Agenda after its implementation period.

Methods

The objective of this work is to carry out a survey through purposive sampling to understand how college student athletes in Taiwan who had at least participated in one sports event at a national level think about the Olympic Agenda 2020 after its implementation period. The athletes were surveyed at the competition venues during the game periods of the national intercollegiate sports events. A total of 528 questionnaires were given out with 446 valid ones collected. The data were then analyzed through the methods of descriptive analysis, paired sample t-test, Pearson correlation analysis and importance-performance analysis.

Results

Among all the surveyors, average 20.9 years old, the highest level they had competed in was mostly intercollegiate level. By analyzing the data of how important and satisfactory athletes felt about the execution of the three pillars of the Agenda with paired sample t-test, significant differences were noticed. Based on IPA, none of the 40 recommendations fell under quadrant B (Concentrate Here) with 29 of them in quadrant A (Keep Up the Good Work), ten in C (Low Priority) and one in D (Possible Overkill).

Discussion

Five years after the adoption of the Agenda, it was still noteworthy that athletes put great emphasis on the recommendations, which corresponded to the research outcomes from Chen, B. I., Chen, M. Y. and Yang, Y. J. (2020) in 2018. Hence, government sectors and related associations should take this into account. Furthermore, in terms of the satisfaction level of the respective aspects of the Agenda, the results revealed an approving tendency, which was different from the outcomes in 2018 when students were not satisfied with the performances in all three priorities. Consequently, it proved that the recommendations were developing in an optimistic direction. When applying IPA, none of the recommendations was in the second quadrant. This finding contrasted with the outcome in 2018 when many of the recommendations were located in quadrant B. Overall, comparing with 2018, this study demonstrated that a progress was made in how athletes perceive the reform and that the efforts made by the government sectors and relevant authorities spoke for themselves.

EXPLORING THE RELATIONSHIP BETWEEN THE SWEDISH REGIONAL SPORT STRATEGY, PERCEIVED TRUST, AND NON-PROFIT SPORT ORGANIZATIONS' MANAGEMENT IN SOUTHERN SWEDEN

ANDERSSON, K., JANSSON, A.
UNIVERSITY OF MALMÖ

Introduction

Sport and trust-based governance is a cornerstone of Swedish sport management. There are more than 20,000 sport associations, and the sport sector receives approximately USD 20 million in public funding yearly. The Swedish Sports Confederation (SSC) is a non-profit umbrella organisation that coordinates the management of Swedish sport. SSC's "what sport wants" is an appropriation document on the vision of the Swedish sport movement wherein SSC advise sport clubs to focus on inclusivity, hard to reach societal groups, and sport for the masses rather than the fostering of elite players. Concurrently, it is problematic that there is no research on what motivates sport clubs to apply what sport wants (Book, Hedenborg & Andersson, 2022). Accordingly, the purpose of this study is to contribute new knowledge on what influences Swedish sports clubs in carrying out what sport wants's national goals for sport participation.

Methods

The data consists of self-rated answers (N = 1,937) from a questionnaire, distributed to all non-profit sport organizations in southern Sweden in 2017, 2018 and 2020. The questionnaire focused on sport organizations' 1) perceived support from SSC, 2) perceived trust in SSC, 3) competence in what sport wants and, 4) how frequently the sports associations worked with equity (including anti-discrimination and inclusion). X2-test and regression analyses were used to analyze differences between the years 2017, 2018 and 2020, and the relationship between perceived support from SSC, perceived trust in SSC, competence in what sport wants, and how frequently the sports association worked with equity. Effect size measurements were calculated and interpreted based on established guidelines.

Results

Preliminary results indicate that sport organizations' perceived support from SSC has decreased significantly and continuously between 2017 (M = 3.0), 2018 (M = 2.9), and 2020 (M = 2.8). It does not seem to be any differences in perceived trust in SSC and equity. The results also show that, competence in what sport wants (β = .225), and perceived support from SSC (β = .278) can predict to which extent sport organizations work with equity (R2 =.278).

Discussion

Preliminary results indicate that more support and trust in SSC lead to increased realization of what sport wants. However, since the results show that perceived support for SSC has decreased between 2017, 2018, and 2020, this study illuminates an urgency of maintaining a strong relationship between Swedish sport clubs and SSC. Moreover, the results confirm the efficiency of the trust-based management model used in Sweden, which seemingly leads to deliverables among the participating associations.

OP-AP08 Network Analysis in Team Sports

AN EXPLORATORY STUDY OF SPATIAL DIVISION OF FOOTBALL PITCH PASSING NETWORKS

MA, R.1,2, CUI, Y.2, DENG, K.2, EXEL, J.1, BACA, A.1

1 CENTRE FOR SPORT SCIENCE AND UNIVERSITY SPORTS, UNIVERSITY OF VIENNA, VIENNA, AUSTRIA; 2 SCHOOL OF SPORTS ENGINEERING, BEIJING SPORT UNIVERSITY, BEIJING, CHINA

INTRODUCTION: The integration of network science into the analysis of football passing performance has recently attracted extensive research interest. Compared to player passing networks, pitch passing networks, which describe zonal information and general attacking profile of a team, have received comparatively less attention. Therefore, this exploratory study focused on determining the optimal spatial divisions of the football pitch passing networks and on examining the most prominent network metrics within such networks regarding zone importance.

METHODS: A dataset consisting of spatiotemporal records of 1,665,510 passes of 1,941 matches from the 2017/2018 season of the top five European Leagues, 2018 World Cup and UEFA Euro 2016 was used. The pitch passing networks were constructed by dividing the field into K equal areas (nodes), with K scales ranging from coarsest (1×2) to finest (20×20). Edges were respectively weighted by the numbers of passes between two nodes. Subsequently, two criteria were applied for determining the division scale: i. the extent of how much passing information was retained (L/N, the ratio of the total links (L) to the total successful passes (N) and ii. the heterogeneity of nodes degree (representing whether passes are evenly distributed under a certain network scale). Kendalls Rank Correlation Coefficient (τ) was used to analyze the association between the ranking of zone importance (based on four key passing events: smart pass, forward pass, assist, key pass) and the following network metrics: degree centrality, clustering coefficient, neighbor degree, closeness centrality, betweenness centrality and eigenvector centrality.

RESULTS: It was shown that the division scales of 24, 50, 100 and 400 contained 81.3%, 90.9%, 95.3%, and 98.9% of all pass information. In addition, no obvious difference in the heterogeneity of node degree was shown between different scales. Regarding the relationship of the ranking of the zone importance at four scales with network metrics, degree centrality, betweenness centrality, eigenvector centrality and closeness centrality showed strong correlations (τ_ave(SD)) of 0.77 (0.121), 0.77 (0.108), 0.75 (0.117) and 0.71 (0.116) respectively, while neighbor degree and clustering coefficient showed trivial correlations of 0.36 (0.234) and 0.18 (0.456).

CONCLUSION: The study indicated that scale divisions from K=24 retains largely the passing information, and the heterogeneity may not be a criterion in deciding optimal scales. Also, areas with higher centrality values contained a greater number of key passing events, which proves the prominence of these areas and potentially aids in future assessments of team passing styles. Nonetheless, it should also be acknowledged that the suitable scale for pitch passing networks may differ depending on analysis purposes. While this study focuses on the micro-level of networks, future research could explore improvements at the meso and marco levels with subgroups or entire networks.

THE INFLUENCE OF SCORELINE ON PASSING PERFORMANCE IN ELITE SOCCER

DING, J.1,3, HUANG, Z.2,3, O'DONOGHUE, P.2, STRAFFORD, B.1, STONE, J.1

1.SHEFFIELD HALLAM UNIVERSITY, 2. RENEJAVIK UNIVERSITY, 3. JT SPORTECH PERFORMANCE SERVICE, CHINA

INTRODUCTION: Passing value (i.e. number of passes or the percentage of successful passing) is regarded as a performance indicator for quantifying a team's style of football [1] with scoring teams achieving greater passing success in the five minutes leading up to a goal [2]. Furthermore, the losing or drawing team typically prefer holding a long possession period, while the winning team play with shorter possession periods [3]. However, the behaviour of passing (i.e. the location, the aim, the type of the passes) has not been examined. Therefore, the aim of this study is to use a self-organising map (SOM) [4] to detect passing patterns and find the association between scoreline and passing behaviours in elite soccer matches.

METHODS: A SOM neural network was trained to classify 192,538 passes in to 12 passing behaviours from 835 high-performance soccer matches. Wilcoxon signed rank tests were used to investigate the changes in passing behaviour frequencies 5 minutes before a goal and during 8 potential scorelines (ATA: Ahead-to-ahead, ATC: Ahead-to-conceded, ATA: Ahead-to-Level, BTB: Behind-to-Behind, BTL: Behind-to-Level, BTC: Behind-to-Score, LTA: Level-to-ahead, LTB: Level-to-Behind). The different percentage of passing behaviour between paired scoring and conceding scoreline was examined by a Chi square test.

RESULTS: 4 significant changes were found in the frequency of passing behaviours between scorelines (except scoreline ATL and BTS). The frequency of pass type 8, Short- and mid- range passes in the central of the pitch towards to the lateral direction (left or right), was different before (0.88±0.33) and after (0.35±0.43) the ATL scoreline ($P < 0.001$). Significant differences were found in the percentage of passing behaviours among total passes before different paired scorelines (scoring teams and conceding teams). Normally, the conceding team played more defensive passes and sided passes (for example ATL: 39.50% defensive, 33.3% aggressive, 77.2% sided, 22.6% central) while the scoring teams play more aggressive and central passes (for example ATA: 31.3% defensive, 39.4% aggressive, 74.8% sided, 25.2% central).

CONCLUSION: Out of 192,538 passes, the chosen artificial intelligence system created 12 classifications 5 minutes before and after goal scoring. Passing behaviours differed significantly across the pre- and post-scorelines, as well as between relative-paired scorelines. This result means in practice, coaches could give instruction to players on how to maintain or change the scorelines in games by tracking and changing the passing behaviours. The influence of scorelines during different times of the game and a unique series of contests on non-location-based passing behaviour in varying leagues with diverse playing styles should be the subject of future research.

CONSTRUCTION OF APPLICATION STRATEGY FOR STATISTICAL ANALYSIS OF BEACH VOLLEYBALL GAME TECHNIQUES AND TACTICS BASED ON THE CONCEPT OF STANDARDIZATION OF RESEARCH METHODS

ZHENXIANG, C., DEFENG, Z., LIN, S., DONG, H.

1.SHANGHAI RESEARCH INSTITUTE OF SPORTS SCIENCE（SHANGHAI ANTI-DOPING AGENCY）, SHANGHAI 200030, CHINA ; 2.SHANGHAI UNIVERSITY OF SPORT, SHANGHAI 200438, CHINA

INTRODUCTION: To explore the establishment of a standardized statistical analysis strategy for beach volleyball techniques and tactics, and to verify its reliability and validity, to provide theoretical standards and methods for studying the technical and tactical characteristics of beach volleyball games, and to lay the theoretical foundation and practical path for the Chinese Volleyball Association to promote the technical statistical methods of beach volleyball.

METHODS: 1. Expert Interview Method: Interviewing 3 professionals.2. Focus Group Discussion: Focus groups are formed by 3 coaches, 6 players, 2 volleyball technical and tactical statistical analysis professionals and 2 researchers to communicate and discuss statistical technical and tactical indexes and effects as well as analysis methods. 3. Experimental method: Fifteen games (60 players) from the final stage of the 14th National Games in 2021 were selected to allow three technical and tactical statisticians to count the games using the Data Volley 4 strategy and one coach at the game site according to the same statistical criteria.

RESULTS: 1. Sorted out the eight modules of "goal setting, index selection, effect standard, related technology setting, tactics setting, statistical standard, hardware and software configuration and practical analysis" to build a standardized technical and tactical statistics strategy; 2. Using the data of 8 matches of the champion Liaoning mens sand volleyball team No. 1 as the sample, using chi-square test and independent sample t-test to compare the final and preliminaries of receiving and serving ($x2=18.67$, $p=0.001<0.05$), attacking ($x2=3.663$, $p=0.61>0.05$), and average block score per set ($t=2.934$, $p=0.011<0.05$) technical performance effects to provide a basis for the selection of the study matches;

3. The intra-group correlation coefficient test application strategy was used and the degree of rater reliability consistency was excellent (all three ICC coefficients >0.90); the paired t-test and Bland- Altman consistency analysis of the average reception rate and offensive success rate per set of applied strategy statistics and traditional paper-and-pencil statistics showed no significant difference ($p>0.05$) and good consistency ($p>0.05$).

CONCLUSION: 1. The standardized system construction of the application strategy can meet the needs of the sand volleyball team in preparing for matches, and at the same time can provide standards and methods for official match technical statistics. 2.The application strategy has good validity and lays the foundation for different statisticians to divide and cooperate. 3. Among the main opponents in preparing for major matches, the latest matches are preferred when choosing the matches.

NEAREST NEIGHBOR CLUSTERING TO RECOGNIZE TEAM TACTICS

SCHWENKREIS, F.

BADEN-WUERTTEMBERG COOPERATIVE STATE UNIVERSITY STUTTGART

INTRODUCTION: Team tactics are coordinated moves of team members as for example in team handball or soccer. Several approaches have been published to detect team tactics automatically in streams of spatio-temporal data as they are generated by Kinexon or Catapult equipment in order to take team tactics into account when evaluating the players' performance. Particularly the representative search based on the clustering data mining technique has been identified lately as a means to solve the task. However, the used notion of distance is critical, and first approaches based on the Frechet distance and straight forward clustering techniques based on distance (and density) have shown suboptimal results.

METHODS: A two-step approach is introduced. First, clusters of player trajectories are identified allowing to "encode" whole team moves as combinations of trajectory cluster ids. Then a variation of a co-occurrence grouping is used to find similar team moves. We need a variation because not all groups of trajectories are "significant" for a team move. Thus, we need to assign significance weights to trajectories when searching for co-occurring trajectory groups.

Usual clustering techniques are suboptimal because they need a more or less constant distance (or density) across clusters. Both, distance and density vary a lot in case of trajectories of players, depending on the played position. Thus, it will be shown that a special notion of nearest neighbor similarity outperforms direct distance or density-based approaches. To find the nearest neighbors of trajectories the dynamic time warping (DTW) distance is used instead of the Frechet distance.

RESULTS: Focusing on a single team of the first German team handball league, 32 matches of that team in 2022 have been analyzed. 7,833 raw player trajectories of attack events have been extracted from the spatio-temporal data collect-

ed by Kinexon during the matches. 5.5 seconds of position information before an attack event (the defense trajectories have not been analyzed yet) were used to search for trajectory groups. By excluding team moves of fast breaks and penalties, the search for tactical moves was based on 732 team moves and 6,153 player trajectories.

Using the two-step approach based on the notion of the dynamic time warping distance, 56 groups of team tactical moves have been identified consisting of 35 groups of player trajectories. However, the 56 groups are partially nested meaning that one group is a special case of another group.

CONCLUSION: Using DTW is a much better distance criterion for trajectories than the Frechet distance. Using the nearest neighbor-based similarity based on DTW rather than using the direct distance allows taking into account the differences of moving patterns of different player positions. It will be shown that the typical trajectories of specific player positions are detected and then grouped to complete tactical moves. And this done in a complete automated process without human video classification.

CARBOHYDRATE INGESTION DURING PROLONGED FATIGUING CYCLING IMPROVES NEXT-DAY TIME TRIAL PERFORMANCE AND MAY REDUCE PROTEIN DEGRADATION IN WELL-TRAINED CYCLISTS

CLAUSS, M.1, SKATTEBO, Ø.1, RASEN DÆHLI, M.1, VALSDOTTIR, D.1, JOHANSEN, E.I.1, SKÅLHEGG, B.2, JENSEN, J.1

1. DEPARTMENT OF PHYSICAL PERFORMANCE, NORWEGIAN SCHOOL OF SPORT SCIENCES, NORWAY. 2. DEPARTMENT OF NUTRITION, UNIVERSITY OF OSLO, NORWAY.

INTRODUCTION: Exercise with low carbohydrate availability increases protein degradation, which can considerably reduce subsequent performance. In parallel, carbohydrate ingestion during exercise has been shown to maintain carbohydrate availability. We aimed to test whether carbohydrate ingestion during exhaustive exercise could reduce protein degradation. In addition, we tested if next-day performance was improved when exhaustion was prevented with carbohydrate ingestion.

METHODS: Seven well-trained male cyclists (VO2max 66.8±1.9 mL·kg-1·min-1; mean±SEM) cycled to exhaustion (~2.5 hours) at a power output eliciting 68% of VO2max (W68%), followed by repeating 1-min work/1-min recovery intervals at 90% of VO2max (W90%) until exhaustion. During W68%, cyclists ingested a placebo water drink (PLA) the first time and a similarly flavored carbohydrate drink (CHO), 1 g carbohydrate·kg-1·h-1, the second time. The participants performed the same amount of work under the two conditions, separated by at least one week. The two conditions were isoenergetic, and diet was provided to the participants. To test the recovery, participants completed a time trial (TT) the next day. TT was designed so that participants completed mechanical work equivalent to 30 min at a workload corresponding to 100% of VO2max. Gross efficiency during TT was calculated as [gross efficiency (%) = work accomplished (kJ)/energy expended (kJ)×100]. Blood and urine were collected throughout the study period. Two-way repeated measures ANOVA was used to determine treatment differences, with treatment and time as factors.

RESULTS: Carbohydrate ingestion maintained carbohydrate availability during W68% and W90%: total carbohydrate oxidation was significantly higher in CHO (CHO, 518±55 g; PLA, 426±31 g; p=0.022), and plasma glucose concentration was maintained in CHO (start, 5.1±0.1 mM; exhaustion, 4.7±0.1 mM; time p=0.523) compared to in PLA (start, 5.2±0.2 mM; exhaustion, 3.7±0.4 mM; time p<0.001; condition p=0.025). Next-day performance during TT was better after CHO ingestion (CHO, 41:49±1:38 min; PLA, 42:50±1:46 min; p=0.020), as well as gross efficiency (CHO, 18.6±0.3 %; PLA, 17.9±0.3 %; p=0.019). Urinary nitrogen excretion did not significantly differ during the study period (p=0.897). Urinary excretion of 3-methylhistidine increased more in PLA than in CHO, but not significantly (p=0.673). Finally, tyrosine and phenylalanine plasma concentrations increased in PLA but not in CHO (p=0.018).

CONCLUSION: Carbohydrate ingestion during exhaustive exercise reduced deterioration in next-day performance through reduced metabolic stress and development of fatigue. Some parameters point toward less protein degradation, which would preserve muscle function, but further investigations are needed. Nevertheless, this study highlights the importance of ingesting carbohydrates during prolonged exercise to maintain subsequent performance, especially when competing over consecutive days.

A DIET RICH IN CARBOHYDRATES WITH LOW GLYCAEMIC INDICES RESULTS IN IMPROVED PERFORMANCE RELATED PARAMETERS IN RECREATIONAL RUNNERS AFTER 10 WEEKS OF ENDURANCE TRAINING

MOITZI, A., ROGI, B., KRUPICKA, R., KOENIG, D.

UNIVERSITY OF VIENNA

INTRODUCTION: Changes in macronutrient intake, such as in a low-carbohydrate high-fat diet (LCHF), are often used to achieve higher fat oxidation rates. LCHF leads to a lower carbohydrate (CHO) oxidation and preserves glycogen stores, because of reduced insulin levels. However, LCHF has shown to decrease metabolic flexibility and performance at higher intensities. Since insulin levels are also lowered in a diet with low glycaemic CHO, we hypothesized that a diet rich in CHO

with low glycaemic indices would combine the fat oxidation-boosting effect of LCHF with the performance-enhancing effects of CHO.

METHODS: 57 male runners (age: 28.3±4.3 yrs, VO2 peak: 55.7±7.8 mL·min-1·kg-1) were randomly assigned to one of three experimental groups (LOW-GI: ≥65% low glycaemic CHO daily, n=19; HIGH-GI: ≥65% high glycaemic CHO daily, n=19; LCHF: ≥65% fat, ≤50g CHO daily, n=19) stratified by their VO2 peak. To determine lactate thresholds, peak power output (PPO), and VO2 peak an incremental test until exhaustion on a treadmill with capillary blood samples taken every 3 min was performed (starting at 6 km·h-1, 1.5 km·h-1 increment, 3 min steps). VO2 peak was measured using breath-by-breath gas analysis. Performance was measured in a 5 km time trial (TT) on a 400m running track. Magnet resonance spectrometry was conducted to measure muscle glycogen content (MG). To test hypotheses one-way ANOVA followed by Tukeys multiple comparisons and paired t-test were used. Significance was accepted at $p<0.05$. Data are reported as mean±SD.

RESULTS: TT improved (LOW-GI: -126±78, HIGH-GI: -78±120, LCHF: -68±92 sec, resp. $p<0.05$) in all three groups, yet, enhancement was 54% higher in LOW-GI compared to LCHF. The increase in relative PPO was greater in LOW-GI (0.26±0.25 W·kg-1) compared to LCHF (0.07±0.16 W·kg-1, $p=0.037$, $\eta^2=0.139$). VO2 peak decreased significantly in LCHF (0.2±0.4 L·min-1, $p<0.05$). A significant increase in performance at 2 and 4 mmol·L-1 thresholds was found in all groups (LOW-GI: 1.5±1.2 and 1.3±0.8 km·h-1, HIGH-GI: 1.2±0.9 and 0.7±1.1 km·h-1, LCHF: 2.1±1.2 and 1.5±0.9 km·h-1, resp. $p<0.05$), changes at 2 mmol·L-1 were most profound in LCHF. Changes in maximum lactate concentration were significantly greater in LCHF (-2.1±1.9 mmol·L-1) compared to other groups ($p=0.008$, $\eta^2=0.198$). Changes in MG were more pronounced in LCHF compared to CHO groups (LOW-GI: 35.4±56.9, HIGH-GI: 31.4±37.2, LCHF: -13.2±35.1 mmol·L wet-tissue-1), but no difference between groups was found ($p>0.05$).

CONCLUSION: These findings demonstrate that a diet rich in low glycaemic CHO appears to increase performance related parameters. Although speculative, these findings could be interpreted as a result of preserved CHO availability, replenished MG and reduced insulin levels. In contrast, LCHF may inhibit training effects at maximal intensities, due to reduced activation of key enzymes in CHO metabolism. Hence, consumption of low glycaemic CHO may be of interest in optimising metabolic flexibility and training adaptions.

THE EFFECT OF DELAYING A CARBOHYDRATE-RICH BREAKFAST ON AFTERNOON INTERMITTENT EXERCISE PERFORMANCE: A RANDOMISED, SINGLE BLIND, PLACEBO-CONTROLLED TRIAL

LAMB, C.1, REES-MILLNS, S.1, LOVE, T.1, WALDRON, M.1, CHEN, Y.C.2, METCALFE, R.S.1

1 SWANSEA UNIVERSITY, 2 NATIONAL TAIWAN NORMAL UNIVERSITY

INTRODUCTION: Omission of a carbohydrate (CHO) rich breakfast has been shown to impair afternoon/evening endurance exercise performance, but previous studies have been limited by a lack of a placebo control and an extreme dietary manipulation (i.e., early morning consumption vs. complete omission). In addition, afternoon/evening exercise performance events commonly involve prolonged durations of high-intensity intermittent rather than endurance-based exercise. In this randomised, single-blind, placebo-controlled study, we tested the hypothesis that delaying the consumption of CHO-rich breakfast would impair prolonged high-intensity intermittent exercise performance in the afternoon.

METHODS: Following ethical approval, ten regular intermittent games players (mean±SD: age: 25±6 y; maximal oxygen uptake: 48±7 ml/kg/min) completed two trials (EARLY and DELAY) that were matched for energy and nutrient intake. In EARLY, participants consumed a high-CHO breakfast shake (2 g/kg BM maltodextrin, 1 ml/kg BM orange squash, 0.15 g/kg BM Xantham gum, 0.067 g/kg BM artificial sweetener and 6 ml/kg BM water) at 8am, followed by a taste and texture matched, but energy depleted, placebo shake (1 ml/kg BM orange squash, 0.15 g/kg BM Xantham gum, 0.067 g/kg BM artificial sweetener and 6 ml/kg BM water) two hours later. In DELAY the order of these shakes was reversed. In both trials, following a standardised and individualised high CHO lunch (888±107 Kcal, 145±28 g CHO), participants subsequently completed a 90-min intermittent indoor cycling exercise performance task, starting at 3pm. This consisted of two, 40-min stages with 10-min of rest in between. Each half involved 18 repeated 2-min blocks of steady state cycling (100-s; 35% maximal aerobic power output), followed by 15-s of unloaded pedalling and then a 6-s all-out sprint. Peak, mean, and end power output were measured during each sprint and averaged across each stage of the test for statistical analysis.

RESULTS: The subjective appetite response followed a similar pattern during the morning of both trials, despite differing blood glucose and substrate oxidation responses, which together confirmed the success of the single-blind placebo control. There were no differences in peak power (1st half: mean difference [95% CI]: 0.85 [-12 to 14] W, $p=0.89$, $d=0.01$); 2nd half: 1.6 [-12 to 15] W, $p=0.79$, $d=0.01$), mean power (1st half: mean difference: 2.2 [-12 to 17] W, $p=0.73$, $d=0.01$); 2nd half: mean difference: -2.2 [-16 to 11] W, $p=0.72$, $d=0.02$) or end power (1st half: mean difference: 6.9 [-11 to 25], $p=0.42$, $d=0.05$); 2nd half: mean difference: -1.7 [-16 to 12] W, $p=0.80$, $d=0.01$) during the sprints in the DELAY compared to the EARLY conditions.

CONCLUSION: These data provide no evidence that delaying consumption of a CHO-rich breakfast impairs prolonged afternoon high-intensity intermittent exercise performance.

THE INFLUENCE OF A VEGAN DIET ON BODY COMPOSITION, PERFORMANCE AND THE MENSTRUAL CYCLE IN YOUNG WELL-TRAINED WOMEN

ISENMANN, E., TROJAK, I., LESCH, A., SCHALLA, J., HAVERS, T., DIEL, P., GEISLER, S.

IST UNIVERSITY OF APPLIED SCIENCES, DUSSELDORF

INTRODUCTION: The number of people who completely renounce animal products and live vegan is continuously increasing. Young women between the ages of 15 and 29 are the most frequently represented population. However, there is hardly any data available for this population. Therefore, this study aimed to examine the influence of a change to a vegan diet and the effects on performance, body composition and menstrual cycle (MC) in young healthy women.

METHODS: Ten well-trained women (>3TE/week) took part in a 12-week controlled study (4 weeks omnivorous control phase, 8 weeks vegan intervention). All participants were informed about the nutritional documentation (FDDB Extender) and a vegan diet one week before the omnivore control phase. In addition, they were supervised by a nutritionist throughout the entire period. Two days before the vegan phase begin, a second information session about the vegan diet was conducted. Every four weeks (T0, T1, T2, T3), performance (squat, countermovement jump (CMJ)) and body composition (body weight, muscle mass (MM), fat mass (FM) were checked and well-being was assessed. In addition, a saliva sample was taken every two days and a menstrual diary was filled out to monitor the MC. A linear mixed model (LMM) was used to test the effects of dietary change on performance, body composition and the MC. Besides, if the change was significant, the influence of the MC phases on body composition and performance was also examined.

RESULTS: No significant changes in squat performance, well-being, and total calories were found (n=9). In CMJ a significant difference in treatment (p:.031) but no time difference (p:.142) was detected. In Body composition a significant decrease over time (p<.001) and treatment effect (p<.001) in MM was observed but not in FM (time: p:.983; treatment: p:.923). In addition, a significant effect of MC phases on MM was observed (p:.023). In macronutrient distribution, the carbohydrate content increased (p<.001), whereas protein content decreased significantly (p<.001). In addition, a negative trend was observed in relative protein intake (p:.050). For fat content, a significant treatment effect was observed (p:002). Hormone concentrations of individual MC showed no significant abnormalities throughout the intervention period.

CONCLUSION: It appears that a change to veganism does not affect squat performance if total calorie requirements are met. In contrast, a significant reduction in CMJ was observed. But, the individual curves show that a considerable reduction in performance was already visible before the vegan phase and cannot be attributed to the vegan diet. The decrease in protein can also be observed in the change in MM. During the vegan phase, the women no longer reach the recommendations for relative protein intake for athletes. Consequently, this could inhibit adaptation or regeneration processes in the long term. However, this can only be speculated at this point. Furthermore, no statement can be made about the long-term effects on MC.

EATING BEHAVIOURS, MENSTRUAL HISTORY, AND THE ATHLETIC CAREER

RAVI, S., VALTONEN, M., IHALAINEN, J.K., HOLOPAINEN, E., KOSOLA, S., HEINONEN, S., WALLER, B., KUJALA, U.M., PARKKARI, J.

UNIVERSITY OF JYVÄSKYLÄ

INTRODUCTION: Sports participation has many health benefits but is also associated with injuries, disordered eating (DE) behaviours, and menstrual dysfunction (MD) in female athletes. This retrospective study aimed to investigate if menstrual history and eating behaviours are associated with sports career-related factors in females who had participated in competitive sports during their adolescence. Moreover, the aim was to evaluate differences in menstrual history and eating behaviours among females with and without a competitive sports background.

METHODS: One hundred females with a competitive endurance sports background and their 98 age-, gender-, and municipality-matched controls participated in the study. Data on demographics, menstrual history, eating behaviours at different age stages, sports careers, and injuries were collected by a questionnaire. Eating behaviours were assessed with the Eating Disorder Examination Questionnaire short form (EDE-QS). EDE-QS scores were calculated for each assessed age period (i.e., ages 13–15, 16–18, 19–21, 22–25, and present) and the scores were used both as a continuous and binary variable. Generalised estimating equations were used to calculate associations of menstrual history and eating behaviours with the outcome variables, i.e., sports career length, participation level, injury-related harms during the career, and career termination due to injury.

RESULTS: Higher EDE-QS scores, indicating unhealthier attitudes toward eating and body image, during the athletic career were associated with a shorter career (B = -0.15, 95% confidence interval (CI) -0.26, -0.05), and secondary amenorrhea was associated with lower participation level (odds ratio (OR) 0.51, 95% CI 0.27, 0.95), injury-related harms during the career (OR 4.00, 95% CI 1.88, 8.48), and career termination due to injury (OR 1.89, 95% CI 1.02, 3.51). Females with a competitive sports background reported higher rates of MD than controls (primary amenorrhea 20% vs 2% in athletes and controls, respectively, p<0.001 and secondary amenorrhea 34.1% vs 20.4%, in athletes and controls, respectively, p=0.035), but no differences between the groups were observed in the EDE-QS scores at any age (p>0.05 for all). However, trends in the EDE-QS scores over time were more stable among controls, while the scores of athletes increased significantly after age 13–15. DE during the sports career among athletes and DE during adolescence or young adulthood among controls was associated with current DE in both groups.

CONCLUSION: The findings of this study indicate that DE behaviours and MD, specifically secondary amenorrhea, are linked with undesirable aspects of a sports career in females competing in endurance sports. DE during the sports career

is associated with DE after the career. Athletes and those working with them should be aware of the negative link of DE and MD to a sports career.

IS-BM05 Sex-Based Differences in Fatigability, Sport Performance and Recovery

SEX DIFFERENCES IN FATIGABILITY AND ATHLETIC PERFORMANCE

HUNTER, S.

MARQUETTE UNIVERSITY

Every cell in the human body has a sex. Consequently, males and females differ in anatomy and physiology resulting in marked sex differences in neuromuscular performance, and fatigability of limb muscles. Typically, males outperform females in athletic and neuromuscular performance after puberty across all age groups primarily due to the effects of testosterone which is ~15-20 times greater than females from ~18 years of age. Males on average have larger, stronger, faster and more powerful skeletal muscles. The sex difference in muscle strength and power range from 10-40% depending on the demands of the task and the muscle groups involved. In contrast, there are minimal sex differences in the ability to activate the available skeletal muscle during voluntary contractions prior to fatiguing tasks.

While males are stronger and more powerful than females, the relative decrement in force or power during a fatiguing task of males is usually larger than for females, primarily for isometric and slow-velocity fatiguing contractions. This sex difference in fatigability (relative exercise induced reduction in force or power) is not typically observed during fast-velocity contractions. This presentation will highlight some of the fundamental differences in physiology and anatomy that dictates the sex differences in athletic performance and fatigability. Understanding the sex difference in neuromuscular fatigability has important implications for training and rehabilitation in males and females.

Finally, despite more concerted efforts in the last ~15-20 years to include females in mechanistic studies, there is still inadequate inclusion of females and knowledge on the mechanisms for sex differences of fatigability and athletic performance. The sex bias of studying more males than females in both human and animal experiments in physiology and fatigability has led to the false assumption that males and females respond similarly to interventions including fatiguing exercise. The field is ripe with opportunities to clarify and understand the sex differences in neuromuscular fatigability, athletic performance, and the underlying mechanisms during different tasks.

DO WOMEN SHOW THE SAME STRUCTURAL AND FUNCTIONAL RECOVERY AS MEN AFTER AN ENDURANCE RACE?

NICOL, C.

AIX-MARSEILLE UNIVERSITÉ

The number of participants in endurance running races has increased dramatically in recent years, especially for the half-marathon. Despite the significant health benefits of regular endurance running, it is characterized by thousands of ground impacts and eccentric muscle actions. This can induce focal structural muscle damage leading to muscle regeneration and functional recovery that last a few days after exercise. Oestrogen however, may make women less prone to muscle fatigue, muscle damage and more rapid recovery of muscle structure and function. Only a few studies however, have analysed the sex-specific recovery pattern, and such comparative analyses have been performed for the acute recovery phase only.

In men, the pattern of functional recovery is described as biphasic, and characterized by immediate functional deficits, followed by partial recovery at 2 h, before new deficits 1 to 2 days later that decrease only gradually over several days. The delayed recovery phase is mainly attributed to the structural and functional consequences of the inflammatory/remodelling processes after exercise-induced muscle damage. This phase is accompanied by delayed onset muscle soreness (DOMS). However, because DOMS is only felt around the inflammatory peak, it disappears before full structural and functional recovery is achieved. This constitutes a potential risk of injury when training resumes as runners may overestimate their actual functional capacities. Furthermore, although a causal relationship between muscle damage and force deficit has been reported after eccentric exercise, only a few running studies have assessed structural and functional recovery of the muscle in parallel other than through indirect blood markers of muscle inflammation (e.g. creatine kinase). Furthermore, whether there are sex-related differences in recovery of muscle from running is not known.

We recently compared the structural and functional recovery patterns of recreational female and male runners after a 20-km gradient race. The inflammatory stage was assessed by ultrasound and magnetic resonance imaging. Women had more DOMS and increases in inflammation markers in the hamstring muscles than men, but no differences in the other muscles. Depending on the test, women had similar or less functional deficits and earlier recovery than men. EMG analysis revealed a sex-specific organisation of muscle synergies that could in part explain the sex differences in recovery

times. For example, women recovered faster in drop-jump, a test in which they showed less hamstring contribution, even in the pre-fatigue session.

Finally, irrespective of sex, the lack of a clear relationship between structural alterations in the muscle and functional deficits is attributed to the various neuromuscular compensations that can occur during dynamic multi-joint contractions.

HORMONAL BASIS OF SEX DIFFERENCES IN ATHLETIC PERFORMANCE

SENEFELD, J.

MAYO CLINIC

The world of sport is facing the challenge of creating sport-specific safeguards that promote fair competition and participation for all athletes - including people who are born with differences of sex development and people who identify as transgender or elsewhere on the gender spectrum. Substantial evidence supports that testosterone is strongly associated with sex-based differences in sports performance, more so than any other known factor. The pronounced differences between the sexes in endogenous testosterone levels beginning at puberty correspond to sex-specific divergence in oxygen carrying capacity in the blood (via hematocrit and hemoglobin); muscle strength and endurance; cardiac output; and sports performance. In this framework, this presentation will use elite athletic performance as a model to provide key insights into the timing and magnitude of sex differences in athletic performance during human development and throughout adulthood.

Before puberty, there are limited differences in athletic performance among elite girls and boys. Thus, this presentation will highlight that youth sports should likely focus on inclusivity and equity between girls and boys.

Beginning with the onset of puberty, sex-based differences in anatomical structure (body, limb, airway, and organ size) develop, such that, on average, people who have undergone male puberty are taller; have longer limbs; have larger lungs and wider conducting airways; and have larger hearts compared to people who have not undergone male puberty. In this context, athletic performance during adulthood will highlight sex-based differences in athletic performance and the key contributing physiological factors. Additionally, the impacts of participation by both males and females will be considered, and the potential role of participation in observed differences in athletic performance.

Finally, this presentation will propose that well-coordinated, multidisciplinary research is needed to provide evidence to support sport-specific safeguards that promote fair competition and participation for all athletes - including people who are born with differences of sex development and people who identify as transgender or elsewhere on the gender spectrum.

IS-PN03 The importance of intramuscular signals on skeletal muscle function in health and disease

ACUTE ADAPTATIONS OF SKELETAL MUSCLE TO EXERCISE: A TRANSLATIONAL APPROACH

PLACE, N.

UNIVERSITY OF LAUSANNE

The transient reduction in muscle force generating capacity after exercise, i.e. muscle fatigue, has been extensively studied for more than a century using different models (from isolated muscle fibre to exercising humans) but there is still no clear consensus about the underlying mechanisms. This lack of consensus might originate from the multifactorial nature of muscle fatigue, potentially involving processes along the whole neuromuscular pathway - from action potential generation at the brain level to the interaction of contractile proteins within the muscle. This presentation will take concrete examples in the literature to illustrate the potential contribution of neural vs. intramuscular factors in the acute adaptations to exercise. Although an arsenal of techniques has been developed to evaluate neuromuscular fatigue in humans, this talk will highlight some of the drawbacks that researchers should keep in mind and provide practical recommendations. We will also show results combining data from various models to emphasize the role of metabolic factors in impaired skeletal muscle Ca2+ handing in response to exercise. As an example, we will discuss the role of the sarcoplasmic reticulum Ca2+ release channel - the ryanodine receptor - as a key regulator of mitochondrial adaptations in response to exercise. This talk is intended to be of broad interest to the sport science community including researchers, sport coaches and clinicians, as it will combine data obtained from non-invasive measurement with more mechanistic investigations for a better understanding of skeletal muscle function.

THE CENTER STAGE OF GLYCOGENOLYTIC DERIVED ENERGY IN SKELETAL MUSCLE FATIGUE

ØRTENBLAD, N.

UNIVERSITY OF SOUTHERN DENMARK

It is well known that glycogen content and turnover is a limiting factor for normal muscle function during both prolonged and high-intensity intermittent exercise. However, the mechanisms explaining why and how glycogen and glycolysis are integrated with muscle function are far from understood. The talk will provide a comprehensive overview of the current understanding of the glycogenolytic regulation of muscle contractile properties. This will bring together recent advance-

ments demonstrating that vital regulations of ions within the cell are controlled locally in micro-domains and that the specific characteristics of glycogen metabolism and glycolysis may provide an essential path for such local control. It is herein remarkable how skeletal muscle fibers to balance energy utilization with production is of vital importance for all cell types, preventing loss of energy and thereby cell integrity, but particularly important in skeletal muscle with a high and fluctuating energy-turnover. Still, the scientific community has mere explanations on how this remarkable precise balance between energy conversion and work is accomplished. We and colleagues in the field have now established research methods to pin-point the mechanisms linking glycogen and glycolytic flux to muscle cell key functions. This has demonstrated that the specific metabolic pathway of glycolysis, which is rate depending on muscle glycogen, is essential for both membrane excitability and calcium regulation. The talk will in line with the overall proposed symposia demonstrate and discuss recent advancements in our understanding of the role of glycogenolytic derived energy, based on experiments from the isolated muscle fibre through to human whole-body exercise, including high level athletes.

INSIGHT INTO HOW INTRAMUSCULAR STRESSORS INTERFERE WITH THE MUSCULAR MACHINERY

LANNER, J.

KAROLINSKA INSTITUTET

Skeletal muscle has an impressive ability to adjust to physiological challenges with enhanced muscle strength and aerobic capacity as examples of beneficial adaptations. However, in disease conditions, and even during normal aging, skeletal muscle may become dysfunctional and weak., i.e., entering a maladaptive state. Both the adaptive and maladaptive alterations to skeletal muscle may occur even without changes in muscle mass, highlighting the importance of the intramuscular machinery for muscle performance, including mitochondria and the contractile apparatus. This presentation will focus on how exercise- and disease-induced intramuscular signals/stressors (including Ca2+, reactive oxygen species, TNFa) contributes to skeletal muscle adaptation and maladaptation. With data from human subjects and preclinical models, emphasis will be put on how intramuscular signals/stressors contribute to reduced mitochondrial health and muscle weakness in subjects with non-communicable disease, for example rheumatoid arthritis and breast cancer. We will also discuss in what manner molecular tools that empower the mitochondrial health can be used to counteract disease-induced muscle maladaptations.

Oral presentations

OP-AP22 Cycling: Training and Testing

CAN WE ACCURATELY PREDICT CRITICAL POWER AND W FROM A SINGLE RAMP INCREMENTAL EXERCISE TEST?

CAEN, K., BOURGOIS, J.G., STUER, L., MERMANS, V., BOONE, J.

DEPARTMENT OF MOVEMENT AND SPORTS SCIENCES, GHENT UNIVERSITY, GHENT, BELGIUM

INTRODUCTION: The critical power model defines the hyperbolic relationship between power output (PO) and its sustainable endurance time by two parameters: critical power (CP) and the work capacity above CP (W'). Theoretically, CP represents the maximal metabolic steady state intensity while W defines a fixed amount of energy available during efforts above CP (1). The practical use of the CP model remains heavily constrained by the necessity to perform multiple exhaustive constant work rate (CWR) tests. Therefore, alternative test protocols have been explored, including a simple ramp incremental test (2), which seems feasible as it can be easily tailored to the individual by adjusting the ramp slope and because these tests are already widely utilized in both sports and clinical practice (3). The purpose of this study was to examine the suitability of a single ramp incremental test to predict critical power (CP) and W. We hypothesized that CP would correspond to the corrected power output (PO) at the respiratory compensation point (RCP) and W would be calcutable from the work done above RCP.

METHODS: 153 healthy young people (26±4 yr, 51.4±7.6 mL·min-1·kg-1) performed a maximal ramp test (20, 25 or 30 W·min-1), followed by a series of constant load trials to determine CP and W. CP (243±46 W) and W (18.7±4.7 kJ) were estimated using a 'best individual fit' approach, selecting the mathematical model with the smallest total error. RCP was identified by means of gas exchange analysis and then translated into its appropriate PO by applying a correction strategy. We evaluated the agreement between CP and the PO at RCP, and between W and the total work done above CP (WRAMP>CP) and above RCP (WRAMP>RCP), as derived from the ramp test.

RESULTS: CP was significantly higher than the PO at RCP (Δ = 8±16 W, $p<0.001$). WRAMP>CP was significantly lower than W (Δ = 1.9±3.3 kJ, $p<0.001$), whereas WRAMP>RCP and W did not differ from each other (Δ = -0.6±5.8 kJ, $p=0.21$).

CONCLUSION: Despite the fact that CP and RCP occurred in very close vicinity, the estimation of W from ramp exercise may be problematic given the likelihood of underestimation and considering the large variability. Therefore, we do not recommend the interchangeable use of CP and W values derived from constant load vs. ramp exercise, in particular when the goal is to obtain accurate estimates or to predict performance capacity.

FORCE-VELOCITY-ENDURANCE RELATIONSHIP: DEVELOPMENT OF A MATHEMATICAL MODEL AND VALIDATION OF THE IFLET TEST

MOREL, B., BOWEN, M., DOREL, S., SAMOZINO, P.

UNIVERSITY SAVOIE MONT-BLANC

INTRODUCTION: Force production capacities during brief maximal efforts are constrained by a force-velocity relationship, a negative linear function characterized by theoretical maximum force (F0) and velocity (V0) [1]. For longer efforts, the intensity-duration relationship is mathematically described by an asymptotic decay function, the asymptote being the critical intensity [2]. Changing the force and velocity produced during an exercise e.g. by manipulating cadences in cycling, modifies the intensity-duration relation [3]. When the effort is prolonged, alterations in force and velocity capacities may also be different. Unfortunately, a unified force-velocity-time relationship as a representation of biomechanical and bioenergetical capacities of exercise performance has never been modeled. The aims of this study were to develop a mathematical model of a force-velocity-time relationship and to validate a test to determine the model parameters.

METHODS: Based on the assumptions that i) the force-velocity relationship is linear and remains so when fatigued and that ii) both the force and velocity capacities decrease over time following an exponential decay function, a mathematical model has been developed. It is defined by 6 parameters being initial force (F0i) and velocity (V0i) capacities, the critical force (F0c) and velocity (V0c) capacities and the time constants for force (TauF) and velocity (TauV) decay. 16 participants realized the IFLET test on two separate days to test the reliability. It consists in a modified cycling 3-min all-out exercise during which the flywheel was instantaneously braked every 30 s so that the participant had to re-accelerate, thus allowing regular evaluation of the force-velocity capacities. The mean force and velocity of each pedal stroke was computed and used to fit the model's parameters.

RESULTS: The goodness of the fit of the model from experimental data was excellent (all $r^2 > 0.93$). F0i and V0i presented no systematic bias, excellent ICC (> 0.9) and very low SEM (< 5%). F0c and V0c demonstrated very good reliability (ICC > 0.8) and low SEM (5.4 and 7.6 %, respectively). TauF and TauV showed good reliability (ICC > 0.75) but higher SEM (~20%). Overall, when looking at the F(v,t) surface, independently of the parameters mentioned above, the relative and absolute reproducibility was very good to excellent.

CONCLUSION: This is the first time that a model describes the force capacity considering both velocity and time simultaneously. This model fitted very well with experimental data obtained during the IFLET test, a 3-min all-out sprint interspersed exercise which also showed very good test-retest reliability. Applications of this approach could be numerous in the evaluation of physical capacities as well as for performance application through training or the optimization of human-material interactions.

MUSCLE TYPOLOGY UNDERPINS SPRINT CYCLING CHARACTERISTICS IN ELITE TRACK CYCLISTS

BELLINGER, P., MINAHAN, C., DERAVE, W., LIEVENS, E., KENNEDY, B., CRAMPTON, M., WACKWITZ, T.

GRIFFITH UNIVERSITY

INTRODUCTION: Maximal power output (i.e., Pmax) and the ability to maintain Pmax (i.e., fatigue rate) are key determinants of track sprint cycling events. Track sprint cyclists have been categorized as possessing fast-typology (i.e., a greater proportion of type II fibres)1,2. Nonetheless, it is unknown whether muscle typology underpins the key characteristics (i.e., Pmax and fatigue rate) of track sprint cycling. The aim of this study was to determine whether muscle typology is associated with the key mechanical characteristics of track sprint cycling in elite track cyclists.

METHODS: Ten male (84.3 ± 8.3 kg) and eight female (66.5 ± 9.4 kg) elite track cyclists volunteered for this study. Five cyclists were classified as world-class athletes, with the remaining thirteen cyclists classified as elite3. Within this cohort, 13 were track sprint and 5 were track endurance specialists. Subjects attended a laboratory testing session where they performed a sprint cycling protocol on either a Lode or custom motor driven SRM ergometer, both with a standard crank length of 170 mm. The laboratory session was comprised of three 5-s maximal sprints completed in isokinetic mode at fixed cadences (80, 120, 160 rev·min-1). Data from the ergometers and power meters were stroked averaged and fatigue free torque- and power-cadence profiles were constructed. Pmax and the corresponding optimal cadence (Fopt) were identified following best practice methodology4. Cyclists then completed two optimised sprints; a 5 s and 15 s maximal effort which were completed at the athletes Fopt, whereby stroke averaged data was used to quantify fatigue per pedal stroke. Carnosine content was quantified by proton magnetic resonance spectroscopy in the gastrocnemius and soleus and expressed as an aggregate Z-score to estimate muscle typology. The association between muscle typology and the

mechanical parameters of the torque- and power-cadence profiles and fatigue rate per pedal stroke in the optimized sprint were analysed using linear regression.

RESULTS: Muscle typology explained 50% and 55% of the variation in Pmax in males and females, respectively (P<0.05), whereby a higher carnosine Z-score (i.e., greater estimated proportion of type II fibres) was associated with a greater Pmax. In contrast, while muscle typology explained 41% of the variation in the fatigue rate of male track cyclists (i.e., a higher carnosine Z-score was associated with a greater fatigue rate), there was a trivial association in female track cyclists.

CONCLUSION: These findings indicate that for male track cyclists there is a trade-off between Pmax and the decrement in power output per pedal stroke with variation in muscle typology, while Pmax is also underpinned by muscle typology in elite female track cyclists.

METABOLIC SIGNATURES OF PERFORMANCE IN ELITE WORLD TOUR PROFESSIONAL CYCLISTS DURING COMPETITION

NEMKOV, T.

UNIVERSITY OF COLORADO ANSCHUTZ MEDICAL CAMPUS

INTRODUCTION: Investigations in elite professional athletes offer a unique opportunity to determine the ceiling of human performance, providing a benchmark to compare human physiology of healthy occasional, recreational, semi-professional and professional athletes. While omics characterizations of recreational and professional athletes under controlled acute training regimens have provided information regarding substrate utilization as a function of exertion, studies are scarce on these processes in elite professional athletes during testing in the field and, more importantly, World Tour competitions.

METHODS: Using dried blood spot collection to circumvent logistical hurdles associated with field sampling, whole blood samples were isolated from 28 international-level professional male cyclists before and after a graded exercise test (GXT) to volitional exhaustion and before and after a long aerobic field training (FT) session (180 km). Additional samples were taken from 5 of these cyclists before and after three stages of a multi-stage World Tour race. Samples were analyzed using high-throughput mass spectrometry-based metabolomics and lipidomics.

RESULTS: Blood profiles of lactate, carboxylic acids, fatty acids and acylcarnitines differed between different exercise modes (GXT and FT). The GXT elicited significant accumulations in lactate and succinate, in addition to significant elevations in free fatty acids and acylcarnitines. Conversely, FT elicited a larger magnitude of increase in fatty acids and acylcarnitines without appreciable increases in lactate or succinate. Comparable signatures were revealed after sprinting and climbing stages, respectively. In addition, signatures of fatty acid oxidation capacity correlated with competitive performance.

CONCLUSION: Collectively, these studies provide a unique view of alterations in the blood metabolome of elite athletes during competition and at the peak of their performance capabilities. Furthermore, they demonstrate the utility of dried blood sampling for omics analysis, thereby enabling molecular monitoring of athletic performance in the field during training and competition.

MIXED-METHOD PRE-COOLING AND SELF-PACED CYCLING PERFORMANCE IN THE HEAT: EFFECTS OF APPARENT TEMPERATURE

RAMOS, J., DUCKER, K., LANDERS, G., RIDDELL, H., GIRARD, O., BRADE, C.

CURTIN UNIVERSITY

INTRODUCTION: It is often believed that pre-cooling (PreC) may only be of benefit to performance when the thermal strain experienced by an individual is sufficiently high, even though this claim is largely unsubstantiated. Thus, the aim of this study was to explore the effects of mixed-method PreC on 20-km cycling time-trial (CTT) performance in various apparent temperatures (AT).

METHODS: Twelve male cyclists or triathletes (mean ± SD: Weekly training distance and frequency = 289 ± 176 km and 5 ± 1, respectively) completed six 20-km CTT separated by 7 days in a randomised order in three different apparent temperatures: hot-dry (31°C, 49% RH; 35°C AT [35AT]), moderately hot-humid (34°C, 55% RH; 40°C AT [40AT]), and hot-humid (36°C, 71% RH; 46°C AT [46AT]) . All trials were preceded by 30 min of mixed-method PreC (crushed ice ingestion 7g·kg-1 body mass + cooling vest) or no cooling (control; CON) in a thermoneutral environment.

RESULTS: During the PreC period, rectal temperature (Tre) was not significantly lower when PreC was applied. However, Tre decreased by 0.01 – 0.02°C/min, which was significantly greater than the rate of decrease in CON ($p < .01$). Mean skin temperature (Tsk) was also 0.70 – 0.87°C lower when PreC was applied compared to CON during the PreC period ($p < .01$). During the CTT, PreC reduced the rate of split time increase in 46AT by 1.14 s/km compared to CON (βdist x temp x int = 1.72, $p < .01$). Further, Tre did not differ between CON and PreC (37.22 vs. 37.03°C, $p > .05$). However, an interaction

effect between condition and distance cycled (βtemp x dist = 0.03, p < .01) indicated that Tre increased over the course of the CTT faster at 46AT (βPreC = 0.11°C/km; βCON = 0.10°C/km) than 35AT (βPreC = 0.07°C/km; βCON = 0.08°C/km). The rate of change in Tsk across the CTT was 0.04°C/km higher when PreC was applied than CON in 46AT only (βtemp x dist x int = 0.04, p < .01). Pre-cooling decreased average rating of perceived exertion compared to CON in 46AT (βint x cond = -1.03, p < .01). Average thermal comfort and sensation during the CTT were significantly lower for PreC compared to CON in 40AT (p < .01) and 46AT (p < .01). Furthermore, the rate of increase in thermal comfort and sensation across the CTT was also higher when PreC was applied (p < .01) compared to CON (p < .01).

CONCLUSION: Although not detrimental to performance, PreC provided the greatest benefit to 20-km CTT performed in hot-humid environmental conditions compared to hot-dry and moderately hot-humid conditions. This may be due to lower mean Tsk and improved exercise-related sensation when PreC is utilised compared to no cooling. Therefore, mixed-method PreC may be of greater benefit to endurance performance when applied in hot-humid environments (>46AT) compared to hot-dry and moderately hot-humid conditions (<46°C AT).

Oral presentations

OP-BM03 Biomechanics: [Muscle and/or tendon function]

IN-VIVO ESTIMATION OF DYNAMIC POSTERIOR TIBIAL TENDON EXCURSION AND TORSION USING ULTRASOUND SPECKLE TRACKING: PRELIMINARY RESULTS

HUNG, K.L., WANG, H.K.

COLLEGE OF MEDICINE, NATIONAL TAIWAN UNIVERSITY

INTRODUCTION: Abnormal torsion of the posterior tibial tendon (PTT) is suggested to be associated with the avascular injury mechanism of tendon degeneration [1]. As dynamic tendon torsion is theorized to present along with tendon excursion during joint motions [2], assessments of both tendon motions are essential in understanding the injury mechanism and prognosis of PTT dysfunction. Ultrasound speckle tracking (UST) is a non-invasive method that can quantify in-vivo tendon motions [3]. The present study utilized UST to investigate tendon excursion and torsion during passive joint motion or isometric muscle contraction and compare outcomes between individuals with neutral and pronated feet.

METHODS: Eight individuals with neutral feet (NE group, age: 25.8±2.28 years) and five individuals with pronated feet (PR group, age: 22.8±2.9 years) were enrolled. All participants were asked to perform passive ankle eversion and isometric ankle inversion tasks on an isokinetic dynamometer. During both tasks, a series of long-axis and short-axis PTT ultrasound images (USIs) was taken sequentially at 2 cm above the medial malleolus using a 4–15 MHz ultrasound probe. UST was then applied to the recorded USIs to calculate speckle displacements within the self-defined region of interest to quantify in-vivo tendon excursion (millimeter) from long-axis images and tendon torsion (degree) from short-axis images. The Mann–Whitney U test was used to evaluate between-group differences.

RESULTS: A significant difference was found in PTT torsion during passive ankle eversion (median [interquartile range]; NE: 3.77° [4.10°], PR: 7.48° [5.14°]; p=0.048; d=1.07) but not during isometric ankle inversion (NE: 3.69° [2.17°], PR: 5.93° [2.04°]; p=0.177; d=0.49) between the groups. No significant between-group differences were noted in PTT excursion during passive ankle eversion (NE: 0.53 [1.10] mm, PR: 1.36 [1.28] mm; p=0.222; d=1.27) and isometric ankle inversion (NE: 1.21 [0.77] mm, PR: 1.75 [3.31] mm; p=0.622; d=0.37).

CONCLUSION: To our knowledge, the present study is the first to report dynamic PTT torsion in vivo. From our preliminary results, as tendon excursion and torsion are suggested to co-occur, more tendon excursion and torsion during passive ankle eversion might imply excessive tendon movement associated with the altered foot posture. However, more participants should be included to further increase the statistical power. Future work should also incorporate measurements of the tendon's mechanical properties to support the hypothesis.

A FORCE-ENDURANCE MODEL ABLE TO DESCRIBE THE MUSCLE FATIGABILITY IN THE SEVERE DOMAIN: VALIDATION ON ELECTRICALLY STIMULATED ADDUCTOR POLLICIS.

VONDERSCHER, M., BOWEN, M., SAMOZINO, P., MOREL, B.

UNIVERSITÉ SAVOIE MONT-BLANC

INTRODUCTION: Muscle fatigue refers to the decay in muscles' ability to generate force. The Critical Power (Pc) concept (1) predicts the point at which fatigue develops in such a way that the required constant intensity will no longer be sustainable, i.e., time to exhaustion (TTE). However, this model only distinguishes two states: when it is possible to continue the exercise or not depending on whether W' (fixed amount of work that can be performed above Pc) is emptied or not. Recently, Bowen et al. (2) extended the Morton's 3-parameters model (3) to describe maximal force decrease over time in

the severe domain, whatever the intensity being constant or variable: Fmax(t) = (-1/Tau) integral(F(t)-Fc)dt + Fi. This study aimed at testing the predictive capacity of this model for constant, ramp, and oscillatory intensities on electrically stimulated Adductor Pollicis in isometric condition

METHODS: A custom ergometer coupled with an electrical nerve stimulation system was developed to study the Adductor Pollicis isometric force production capacities, independently of participants' voluntary activation. While participants remained passive, a PID control regulated ulnar nerve stimulation discharge frequency between 6 and 30 Hz to follow a force target. Maximal capacities (Fmax) were assessed every 15 s with 100 Hz tetanus of 500 ms duration. Eight participants realized 3 experimental sessions. The individual parameters Fi, Fc and Tau were determined by adjusting the model to Fmax and time data from constant intensity tests. Model's validity was tested through the accuracy of the model's prediction of i) exhaustion times during increasing ramp tests and ii) Fmax(t) during an oscillatory force exercise (sinus function between Fc and Fc + 0.1 Fi with a 120 s period).

RESULTS: The model's goodness of the fit on constant exercise experimental data was excellent (median adjusted R2 = 0.96; interquartile range = 0.15; RMSE = 4.4 ± 2.7 %Fi). Mean ± SD Fi, Fc and Tau were respectively 95.9 ± 1.2 %Fi, 22.4 ± 4.1 %Fi and 39.9 ± 15.5 s. Mean difference between predicted and observed TTE was 8.9 ± 18.2 s (RMSE = 9.7 ± 5.2 %Fi). The RMSE between predicted and observed Fmax during the oscillatory test was 6.1 ± 3.1 %Fi.

CONCLUSION: The present results evidenced that it is possible to determine individual model's parameter Fi, Fc and Tau from experimental data obtained during electrically induced isometric contractions of the Adductor Pollicis. Moreover, once individually fitted, the model showed very good predictions of the time to exhaustion in an increasing ramp test. Finally, the proposed model allowed for the accurate prediction of fatigue, i.e., decrease in maximal force, over an oscillatory fatiguing exercise. To conclude, the force-endurance capacities mathematical model seems valid to characterize muscle-level isometric fatigability in the severe domain, independently from central mechanisms.

EVIDENCE OF DIFFERENT SENSITIVITY OF MUSCLE AND TENDON TO MECHANO-METABOLIC STRESS

LAMBRIANIDES, Y., EPRO, G., KARAMANIDIS, K.

LONDON SOUTH BANK UNIVERSITY

INTRODUCTION: Inability of tendons to match muscle strength gains in response to exercise could lead to an imbalance between these structures and place the tendon under a higher mechanical demand (i.e. higher strain; 1). The current investigation aimed to examine the effects of mechano-metabolic stress on the temporal dynamics of triceps surae (TS) muscle and Achilles tendon (AT) mechanical and morphological adaptive changes by conducting fatiguing cyclic mechanical loading exercise at low and high muscle force generation capacity.

METHODS: Twelve young adults (27±5 yrs) completed a 12-week training intervention of 3 weekly sessions of 3 sets of cyclic unilateral isometric plantarflexion contractions at 80% of maximal voluntary contraction until failure to induce high muscle metabolic stress. As TS muscle operates on the ascending limb of the force-length-relationship (2), a short (PF; 115º) or a long (DF; 85º) muscle-tendon unit (MTU) length was used for each leg during exercise to achieve low and high levels of mechanical stress, respectively. TS MTU mechanical and morphological properties were assessed biweekly via simultaneous ultrasonography and dynamometry. All three compartments of the TS muscle and the AT were 3D reconstructed using magnetic resonance imaging.

RESULTS: Similar temporal adaptive increments in TS muscle strength, pennation angle and cross-sectional area were found between DF and PF legs over the 12 weeks of cyclic fatiguing loading exercise ($p<0.05$). DF leg demonstrated a significantly higher AT stiffness post 12 weeks of training (pre 473 ± 106 vs. post 12wk 523 ± 107 N/mm; $p<0.05$) along with greater AT CSA, with no observable changes in AT force-length relationship for the PF leg. In both legs, maximal AT strain followed a similar temporal increase within the first 8 weeks (on average relative tendon strain increase ≈15%), after which a continuous reduction towards baseline levels was observed only in the DF leg. The PF leg demonstrated a further increase until the end of the 12-week intervention (on average from 5.4 to 6.6%).

CONCLUSION: The current findings provide evidence that muscle and tendon responsiveness to mechano-metabolic stress over time differs in rate and magnitude, and that muscle is more sensitive to metabolic stress and muscle activation, whereas tendon adaptation depends primarily on the magnitude of experienced stress and strain. We propose that such differences between muscle and tendon sensitivity to mechano-metabolic stimuli can temporarily lead to higher functional demand on the tendon and need to be considered to reduce the risk of unbalanced adaptive changes within the MTU during exercise.

TORQUE-ANGLE AND TORQUE-VELOCITY RELATIONSHIPS DURING UNILATERAL LEG EXTENSIONS: TOWARDS AN INDIVIDUAL TORQUE-VELOCITY-ANGLE PROFILE

POMMERELL, F.1, RAHMANI, A.1, BOYAS, S.1, SAMOZINO, P.2, MOREL, B.2, PEYROT, N.1

1 LE MANS UNIVERSITÉ, LABORATOIRE MOTRICITÉ, INTERACTIONS, PERFORMANCE, UR 4334, FRANCE ; 2 UNIVERSITÉ SAVOIE MONT-BLANC, LABORATOIRE INTERUNIVERSITAIRE DE BIOLOGIE DE LA MOTRICITÉ, UR 7424, FRANCE

INTRODUCTION: Torque production for single- or multi-joint movements depends on joint angle and angular velocity due to the muscle force-length and force-velocity relationships[1]. Therefore, to characterise individual strength variations with joint angle and angular velocity can be useful to better understand and enhance human performance.

A three-dimensional model constructed from Hill's hyperbolic Torque-angular Velocity (T-V) and Torque-Angle (T-A) relationships modelised by a second order polynomial can be used to describe the Torque-Velocity-Angle (T-V-A) relationship[1]. However, this model is based on some assumptions, such as: 1) the optimal joint angle (A0) at which the maximal torque is produced for a given angular velocity is independent on the angular velocity, and 2) the T-V relationship can be modelised by the Hill's function over the entire angle spectrum. So, in order to validate these assumptions, the purpose of this study was to test 1) the A0 independence from velocity, 2) the degree of fitting (r^2) of Hill's hyperbolic T-V model for different joint angles, and 3) the consistency of the T-V relationships parameters (theoretical maximal torque, T0, and angular velocity, V0; curvature of the T-V relationship, C).

METHODS: Seven active participants randomly completed maximal intensity isokinetic knee extensions at 21 angular velocities (30 to 450°/s). Range of motion was set from 0 (full extension) to 110° knee flexion.

A0 was calculated for each angular velocity from the second order polynomial T-A relationships. A0 coefficients of variation were calculated to determine the deviation of A0 across velocities.

T-V relationships from Hill's hyperbolic function at different knee angles were modelised from experimental torque, angle and angular velocity data. T0, V0 and C were then extrapolated. Repeated measures ANOVAs were used to test differences in T-V relationship parameters (T0, V0, C and r^2) at three knee angles: A0-30°, A0-15°, A0.

RESULTS: Maximal torque occurred between 64 to 80°, resulting in a mean A0 of 72±8° knee flexion. The mean coefficient of variation was 6.72±4.08% illustrating that A0 remains stable across velocities.

T0 was significantly lower at A0-30° (156±17 N.m) than at A0-15° (194±23 N.m), and lower at A0-15° than at A0 (223±27 N.m).

Despite a high-level fitting (r^2>.85), V0 and C did not significantly change according to the knee angle, probably because of the high variability of the modelised values illustrated by a small effect size (η^2=0.005).

CONCLUSION: The optimal knee angle does not depend on the contraction velocity. Maximal torques obtained by Hill's hyperbolic extrapolation varied according to the second order polynomial torque-angle relationships. This result confirms the independent effect of angle and angular velocity in torque production. Further studies should include experimental data closer to the maximal knee angular velocity to improve model parameter adjustments, mainly V0 and C.

TRICEPS SURAE MUSCLE-TENDON UNIT MECHANOBIOLOGICAL RESPONSES TO FREQUENT HIGH MAGNITUDE OF MECHANICAL LOADING

EPRO, G.1, SUHR, F.2, KARAMANIDIS, K.1

1 LONDON SOUTH BANK UNIVERSITY; 2 UNIVERSITY OF BAYREUTH

INTRODUCTION: Muscle strength gains in response to long-term exercise are commonly accompanied by increased tendon stiffness (1), which is reported to increase tendons tensional load resistance. Over shorter timeframes muscles however react to mechanical loading at faster tissue renewal rates than tendons (2). Accordingly, frequent exercise with limited resting periods may lead to a net degradation of tendon matrix (3), potentially causing a higher mechanical demand for the tendon (i.e. increased strain). The current study examined the effects of consecutive repetitive high strain cyclic loading with different resting periods on triceps surae (TS) muscle-tendon unit (MTU) mechanical properties and extracellular matrix turnover-related biomarkers.

METHODS: Eleven young healthy male adults (26±6 yrs) underwent 12 consecutive days of isometric resistance exercise for ankle plantarflexors using high AT strain cyclic loading (90% MVC). Participants exercised one leg once a day (~24h rest; low dose) and the contralateral leg three times a day (~2h rest between sessions within day; high dose). TS MTU mechanical properties (maximal AT force, maximal AT strain and AT stiffness) were assessed at baseline, every second day of exercise intervention and 48h after last day (i.e. retention effects) using synchronized dynamometry, ultrasonography and motion capture. Further, extracellular matrix turnover-related biomarkers concentrations were determined from serum along the exercise period.

RESULTS: Similar increase in maximal AT force (~10%) was observed along the 12-day exercise period in both legs. While low dose exercise did not alter the AT mechanical properties, high dose leg showed ~20% increase in maximal AT strain along with a corresponding decrease in AT stiffness already after 8 consecutive days of high AT strain cyclic loading, an effect which remained even after 48h of rest ($P<0.05$). However, when adjusting for total training volume no significant leg-differences in tendons force-length-relationship were observed. Extracellular matrix biomarker analysis revealed no

inflammatory responses, but an altered collagen turnover and delayed increase in collagen type I synthesis rate. Further, biomechanical and biochemical measurements were supported by gradually higher perceived AT pain in the high dose trained leg.

CONCLUSION: This study indicates that frequent high strain cyclic loading exercise can lead to a persistent elevated tendon strain, potentially due to an accumulation of molecular damage within the tendon. One decisive factor to exercise-related increase in tendon strain seems to be the total experienced volume of mechanical loading. Hence, high cyclic mechanical loading over short timeframes may overweigh tendon's recovery leading to an increased demand and decrease tendons' tensional load resistance.

IS-EX02 FEPSAC invited symposium - Psychological perspectives on sport injuries

IMPLEMENTATION OF PSYCHOLOGICAL BASED STRATEGIES FOR INJURY PREVENTION

IVARSSON, A.

HALMSTAD UNIVERSITY

There are high injury rates associated with sport participation, both on grassroot as well as lite level. Taking this into consideration-together with the negatively consequences at the individual, team/club, and community levels-the development of preventive programs and strategies for sport injuries are important. In the process of developing effective preventive programs and strategies, the first step is to identify risk factors that will increase the likelihood of sport injuries. In the history of research focusing on risk factor and prevention of sport injuries, the dominant perspectives have been physiological and/or biomechanical During the last three decades, the role of psychological factors in sport injury prevention has, however, gained more attention. The aims of this presentation are to: (a) present psychosocial risk factors for injuries, (b) describe potential mechanisms for the relationship between the presented risk factors and sport injuries, and (c) discuss the development and implementation of psychological based injury prevention programs. In relation to the first aim (a) the focus will be to present psychosocial risk factors for sport injuries. Following the presentation of risk factors, I will also explain how these risk factors might influence injury risk (aim b). Related to the last aim (c) I will present the designs and effects of injury prevention programs implemented in different sports. Despite most studies having shown that psychological based training programs can reduce the number of injuries within several different sports, there are few teams, clubs, or organisations that have included this type of training into their general injury prevention programs. There might be several reasons for the rather unsuccessful implementation of this type of content into general prevention practice. I will, therefore, also discuss aspects that can improve the implementation of psychological strategies within the injury preventive work for sport clubs. This talk is relevant to researchers and clinicians wishing to understand the how psychological techniques and strategies can be implemented to prevent sport injuries within various sporting contexts.

PSYCHOLOGICAL INTERVENTIONS TO OPTIMISE POST-INJURY RECOVERY

VAN DE WOUW, A.

PRIVATE PRACTICE

For competitive athletes the chance of sustaining an injury during a regular season is fairly high. One could argue that injury is an inevitable part of engaging in sport.

In prevention and rehabilitation of sport injuries, the primary focus of sports medicine professionals is on the physical aspects. However, psychosocial variables also influence both injury risk and injury rehabilitation outcomes (1). A variety of psychosocial interventions both pre-and post-injury have been developed and scientifically evaluated, but these are often overlooked (2).

In adopting a holistic perspective on injuries, the aim of this presentation is to: (a) examine psychological interventions that have been shown to optimise post-injury recovery, (b) articulate benefits of these interventions and (c) discuss ways of implementing them in rehabilitation programmes.

In regards to aim (a), research indicates that psychosocial interventions can facilitate post-injury recovery by managing fear and anxiety, increase motivation, positively influence therapy compliance and speed up the rehabilitation process (3). Psychosocial interventions shown to be effective are: relaxation, imagery, goal setting, self-talk, self-confidence, social support and effective physician-patient communication (3). The focus of this talk will be on relaxation and imagery. In relation to aim (b), the use of deep breathing or voluntary muscle relaxation techniques during physical rehabilitation has shown to decrease anxiety and pain, and to speed physical recovery (3). Using imagery results in a faster recovery time from injury (3). Finally, for aim (c), various ways of integrating relaxation and imagery exercises in rehabilitation pro-

grammes will be discussed. Examples will be given from my experience working with injured athletes and sport medicine professionals. Key is integrating the interventions into the daily rehabilitation schedules, providing information, communication, co-operation and education.

This talk is relevant to clinicians, injured athletes, coaches and researchers wishing to know more about psychological interventions optimising post-injury recovery, the benefits of these interventions and how they can be implemented.

A RELATIONAL PERSPECTIVE ON THE RETURN TO SPORT FOLLOWING INJURY

PODLOG, L.

UNIVERSITÉ DE MONTRÉAL & CHU SAINTE-JUSTINE RESEARCH CENTRE

Over the past 20 years, research has shed light on a variety of psychological factors influencing athlete's return to sport following injury. The return-to-sport (RTS) refers to the time frame when athletes are transitioning from the completion of rehabilitation (or recommended rest period) to sport-specific training and competitive performances. While much of the research to date has focused on variables impacting athletes' RTS, an exclusive focus on the athlete neglects the fact that returning athletes can impact and be impacted by relevant others in the rehabilitation environment. The latter focus has been referred to as a relational perspective on sport injury. In adopting a relational perspective on the RTS, the aim of this presentation is to: (a) examine returning athlete's impact on key injury stakeholders, (b) articulate benefits of a relational perspective and (c) discuss future relational research on the RTS. In regards to aim (a), initial research suggests that a returning athlete can have a range of positive and negative effects on coaches, teammates, family/friends, and sport psychologists. For example, coaches may experience benefits of a returning athlete such as: more options in team-selection, bolstering and reinvigorating the team atmosphere, and increasing the likelihood of achieving key performance objectives (e.g., winning a game or league). A returning athlete may also have negative impacts on others. In one study, parents reported their fears of their children getting re-injured, while in another report, a sport psychologist described feelings of guilt, professional incompetence and sleeplessness after informing a returning athlete that re-injury was highly unlikely, only for the athlete to experience an ACL re-tear in her first competition back. In relation to aim (b), adopting a relational perspective can broaden the scope of inquiry to include key injury stakeholders, can provide important information for helping injury stakeholders better cope with the injury experience, and can influence the development of sport injury models and frameworks for investigating key interactions and dynamics surrounding injury management. Finally, for aim (c), I will discuss various future research directions, such as the need to further explore the impact of athletes' RTS on sport medicine providers (e.g., physiotherapists) and to examine RTS interactions between injury stakeholders (e.g., discussions between coaches and physiotherapists regarding RTS decisions). This talk is relevant to researchers and clinicians wishing to understand the impact of injury on others and injured athletes interested in understanding their impact on various injury stakeholders.

EXOGENOUS KETOSIS IMPROVES HYPOXIC TOLERANCE AND MAINTAINS BLOOD OXYGEN SATURATION IN HYPOXIC CONDITIONS.

STALMANS, M., HESPEL, P., DEBEVEC, T., POFFÉ, C.

KU LEUVEN

INTRODUCTION: High-altitude exposure, especially when the altitude exceeds ~2000m, poses individuals at risk to develop acute altitude sickness which becomes more and more prevalent with further altitude increases (1). This is primarily due to a drop in partial oxygen pressure resulting in hypoxemia (2). Intriguingly, we have recently shown that elevating blood ketone bodies via ketone ester (KE) ingestion increases blood oxygen saturation during exercise (3). Therefore, we investigated whether KE intake could counteract the drop in blood oxygen saturation and the development of acute altitude sickness during an intermittent exercise protocol at high-altitude.

METHODS: In a randomised crossover design, thirteen subjects participated in two experimental sessions in a normobaric hypoxic facility set at a simulated altitude of 4000m (FiO2: 12.7 %O2). During the 28 hour protocol, subjects performed five 30-min submaximal exercise bouts (1.5 W.kg-1), to simulate the workload associated with normal ascend rates to alpine huts and summits, interspersed by passive recovery. Throughout the protocol subjects received either placebo (CON) or ketone ester (KE), with the specific aim to induce a stable physiological ketosis at ~3 mM throughout the day. Immediately

after entering the hypoxic room (0h) and after 4h of hypoxic exposure, blood oxygen saturation (SpO2), oxygen uptake (V02) and minute ventilation (VE) were assessed in a resting state. Subjects were asked to comply to the 28 hour protocol until voluntary resignation. A paired t-test and two-way repeated-measures ANOVAs were performed to evaluate differences between the experimental conditions.

RESULTS: In KE, blood D-β-hydroxybutyrate concentrations were stable at ~3-4 mM during the diurnal phase of the hypoxic residence, while they remained low (~0.3 mM) in CON ($p < 0.05$ for KE vs. CON). KE increased duration of compliance to the protocol by 29% (CON: 16.0 ± 10.1h vs. KE: 20.7 ± 9.5h, $p = 0.028$). Blood SpO2 dropped by 6.3% in CON throughout the first 4h in hypoxia ($p < 0.001$), but remained stable in KE ($p > 0.999$). As such, blood SpO2 values were higher in KE vs. CON after 4h ($p = 0.007$). V02 concomitantly increased by 10% in CON ($p < 0.001$), yet remained stable in KE ($p = 0.982$), while VE increased by 17% in both conditions ($p < 0.001$).

CONCLUSION: These data indicate that KE ingestion delays the development of high altitude sickness. We provide preliminary evidence that this is related to an inhibition of the drop in blood oxygen saturation level and the increase in oxygen consumption during hypoxic residence.

EXOGENOUS KETOSIS IMPROVES SLEEP EFFICIENCY AND COUNTERACTS THE DECLINE IN REM SLEEP FOLLOWING STRENUOUS EXERCISE

ROBBERECHTS, R., ALBOUY, G., HESPEL, P., POFFÉ, C.

KU LEUVEN

INTRODUCTION: Available evidence indicates that strenuous exercise impairs sleep quality and quantity (1). Interestingly, a study in rodents suggests that ketone bodies may improve sleep quality (2). Therefore, we determined whether increasing blood ketone bodies, by ketone ester (KE) ingestion, could counteract sleep disruptions induced by strenuous exercise.

METHODS: In a randomised crossover design, ten well-trained cyclists participated in two experimental sessions each involving a morning endurance training and an evening high-intensity interval training ending one hour before sleep. Following exercise, sleep architecture was assessed during the night using polysomnography. Post-exercise and 30min before sleeping time, subjects received either 25g KE (EXKE) or a placebo drink (EXCON). A third session without exercise, but with placebo supplements (RCON) was added to evaluate the effect of exercise per se on sleep. A one-way and two-way repeated-measures ANOVA or a linear mixed model was performed to evaluate differences between the experimental conditions.

RESULTS: Blood D-β-hydroxybutyrate concentrations transiently increased to ~3mM post-exercise and during the first part of the night in EXKE but not in EXCON or RCON. Exercise significantly reduced REM sleep by 26% ($p = 0.001$ vs. RCON) and increased wakefulness after sleep onset (WASO) by 95% ($p = 0.004$ vs. RCON). Interestingly, KE improved sleep efficiency by 3% ($p = 0.040$ vs. EXCON) and counteracted the exercise-induced decrease in REM sleep ($p = 0.011$ vs. EXCON) and the increase in WASO ($p = 0.009$ vs. EXCON). This was accompanied by a KE-induced increase in urinary dopamine excretion ($p = 0.033$ vs. EXCON). In addition, exercise increased sleep spindle density by 36% ($p = 0.005$ vs. RCON) suggesting an effect on neural plasticity processes during sleep.

CONCLUSION: These data indicate for the first time that KE ingestion improves sleep efficiency and quality following high-intensity exercise. We provide preliminary evidence that this might result from KE-induced increases in dopamine signalling.

THE EFFECT OF EIGHT-DAYS ORAL TAURINE SUPPLEMENTATION ON THERMOREGULATION AT FIXED HEAT PRODUCTION IN HOT CONDITIONS OF INCREMENTAL HUMIDITY: A DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL

PEEL, J.S.1, MCNARRY, M.A.1, HEFFERNAN, S.M.1, NEVOLA, V.R.1,2, KILDUFF, L.P.1,3, WALDRON, M.1,3,4

1SWANSEA UNIVERSITY, UK.; 2DEFENCE SCIENCE AND TECHNOLOGY LABORATORY , UK.; 3WELSH INSTITUTE OF PERFORMANCE SCIENCE, SWANSEA UNIVERSITY, UK.; 4UNIVERSITY OF THE SUNSHINE COAST, AUSTRALIA.

INTRODUCTION: Exercise in hot and/or humid environmental conditions can cause positive heat storage, if thermal equilibrium is not maintained through sufficient dry or latent heat dissipation (Eskin) [1]. This may lead to uncompensable heat stress, denoted by inexorable increases in core temperature (Tcore) [2]. To delay the upward inflection of Tcore, thermal sweating and the efficiency of evaporative heat transfer can be enhanced through interventions, such as heat acclimation [2]. Similarly, taurine supplementation has been shown to increase sweat rate and hasten the onset of sweating during exhaustive exercise in the heat [3], but its potential role in thermoregulation has not been thoroughly evaluated. The aim of the current study was to determine the effect of an eight-day taurine supplementation period on Tcore and sweating responses, calorimetric heat transfer components (Eskin, heat storage), plasma volume and plasma taurine concentrations during prolonged exercise of a fixed heat production (Hprod) in hot conditions at both fixed, and incremental vapour pressures.

METHODS: Fifteen healthy, non-heat acclimated females (n = 3) and males (n = 12; 27 ± 5 years) completed a treadmill walking protocol in the heat (37.5 ± 0.1°C) at fixed- and ramped-humidity, following one-week of oral taurine supplementation (50 mg/kg/bm) or placebo in a double-blind, randomised, placebo-controlled, cross-over design. Participants were assessed for whole-body sweat loss (WBSL), local sweat rate (LSR), sweat gland activation (SGA), core temperature (Tcore), point of uncompensability (Pcrit) and calorimetric heat transfer components (Eskin and heat storage). Plasma volume and plasma taurine concentrations were established through pre- and post-trial blood samples.

RESULTS: Taurine supplementation increased WBSL by 26.6% and 5.1% (p = 0.035), LSR by 15.5% and 7.8% (p = 0.013), SGA (1 x 1 cm) by 32.2% and 29.9% (p < 0.001) and SGA (3 x 3 cm) by 22.1% and 17.1% (p = 0.015) during the fixed- and ramped-humidity exercise periods, respectively. Evaporative heat loss (Eskin) was enhanced by 27% (p = 0.010) and heat storage was reduced by 72% (p = 0.024). Pcrit was greater in taurine vs. placebo (p = 0.002), as was plasma taurine concentration (p = 0.001).

CONCLUSION: Taurine supplementation increased sweating responses during fixed Hprod in hot conditions, prior to substantial heat strain and before the point of uncompensability. The enhanced evaporative cooling and reduced heat storage delayed the subsequent upward inflection in Tcore – represented by a greater Pcrit. The apparent taurine-induced augmentation of the sweating response offers preliminary evidence for the use of this dietary supplementation strategy to support thermoregulation in humans during exercising heat stress.

ALGAE INGESTION INCREASES RESTING AND EXERCISED MYOFIBRILLAR PROTEIN SYNTHESIS RATES TO A SIMILAR EXTENT AS MYCOPROTEIN IN YOUNG ADULTS.

VAN DER HEIJDEN, I., WEST, S., MONTEYNE, A.J., FINNIGAN, T.J., ABDELRAHMAN, D.R., MURTON, A.J., STEPHENS, F.B., WALL, B.T.

UNIVERSITY OF EXETER

INTRODUCTION: Algae are protein and essential amino acid rich, sustainably produced food sources. As such, several species are potential non-animal-derived dietary protein sources to stimulate myofibrillar protein synthesis (MyoPS); however, in vivo human data are lacking. We assessed the impact of ingesting isonitrogenous boluses of spirulina ('blue-green algae' or cyanobacterium; Arthrospira platensis) or chlorella (microalgae; Chlorella vulgaris) compared with an established high quality non-animal-derived dietary protein source (fungal-derived mycoprotein) on plasma amino acid concentrations, and resting and post-exercise MyoPS in young adults.

METHODS: Thirty-six healthy young adults (age: 22±1 y; BMI: 23±0 kg/m2; male [m]/female [f], 18/18) participated in a randomised, double-blind, parallel-group trial. Participants received a primed, continuous infusion of L-[ring-2H5]-phenylalanine and completed a bout of unilateral resistance leg exercise before ingesting a drink containing 25 g protein from either mycoprotein (MYCO; n=12; m/f, 6/6), spirulina (SPIR; n=12; m/f, 6/6), or chlorella (CHLO; n=12; m/f, 6/6). Blood and bilateral muscle samples were collected at baseline, and during a 4-h postprandial and post-exercise period to assess plasma amino acid concentrations and MyoPS rates in rested and exercised tissue. Two- and three-way ANOVAs were used to detect differences in plasma amino acid concentrations (time × group) and MyoPS rates (time × group × leg), respectively (with Bonferroni post-hoc tests applied to detect individual differences).

RESULTS: Protein ingestion increased plasma total (TAA) and essential (EAA) amino acid (and leucine) concentrations (time effects; all P<0.001), but most rapidly and with higher peak responses following ingestion of SPIR vs MYCO and CHLO (P<0.05), and MYCO vs CHLO (P<0.05). Protein ingestion increased MyoPS rates (time effect; P<0.001) in both rested (MYCO, from 0.041±0.01 to 0.060±0.004%·h-1; SPIR, from 0.043±0.009 to 0.067±0.007%·h-1; and CHLO, from 0.037±0.002 to 0.055±0.005%·h-1, respectively) and exercised (MYCO, from 0.046±0.004 to 0.092±0.007%·h-1; SPIR, from 0.036±0.003 to 0.087±0.009%·h-1; and CHLO, from 0.048±0.005 to 0.090±0.007%·h-1, respectively) tissue, with no differences between groups (interaction effect; P>0.05), but with higher rates in exercised compared with resting muscle (time × leg effect; P<0.001).

CONCLUSION: Ingestion of protein-rich boluses of algae robustly increases resting and post-exercise MyoPS rates, and to a comparable extent as a high-quality non-animal-derived protein source, despite divergent postprandial plasma amino acid responses. These mechanistic data are the first to indicate microalgae and cyanobacteria as viable alternative protein sources to acutely support (post-exercise) skeletal muscle reconditioning.

EFFECTS OF REDUCING DIETARY PROTEIN ON PERFORMANCE AND BODY COMPOSITION IN WELL-TRAINED ENDURANCE ATHLETES

ALMQUIST, N.

UNIVERSITY OF COPENHAGEN

INTRODUCTION: Dietary protein intake is high among athletes, but the actual requirement for protein in endurance athletes has not been directly assessed in a controlled longitudinal dietary intervention study with performance outcomes.

Reducing protein intake in endurance athletes allows for higher carbohydrate intake, ensuring glycogen replenishment between daily exercise sessions, which may be beneficial for performance and training adaptations.

METHODS: Here, we investigated performance in well-trained cyclists and triathletes (maximal oxygen uptake; VO2max, mean±SD: 61±5 ml·min-1·kg-1) before and after a 6-week controlled, eucaloric, dietary intervention. After a 3-week run-in period with diet- and activity registration, participants were randomized into a control group continuing their habitual, normal diet (NP, n=7; 2.4±0.4 g protein·kg-1·d-1, 53±1E% carbohydrate) and a reduced protein group with carbohydrate replacement (RP, n=7, 1.07±0.07 g protein·kg-1·d-1, 64±1 E% carbohydrate). Dietary fat intake was matched (30±1 E%) and in accordance with their habitual diet. All foods were weighed to 1 gram of accuracy and delivered to the participants. Daily activities and body composition were carefully monitored before and throughout the intervention, and habitual training volume was maintained throughout the intervention (~15±4 h·wk-1). Cycling performance was evaluated during a 100-min cycling protocol including a 10-sec all-out sprint, an incremental test to exhaustion to determine VO2max, a 1-min maximal aerobic power (Wmax), and was finalized with a 15-min maximal test in the fatigued state.

RESULTS: Preliminary data show that both groups maintained lean body mass (RP: 63.5±5.7 kg vs. 63.2±5.0 kg, NP: 59.0±3.8 vs. 59.6±3.4 kg pre and post 6 weeks, respectively). Performance in a fresh state was unaltered in both groups from pre-, to post-intervention (relative changes in VO2max: RP: 1±4%, NP: 0±2%; Wmax: RP: 1±2%, NP: 0±2%; 10-sec mean power output: RP: 2±5%, NP: 1±3%, interactions p>0.05). The dietary interventions did not affect 15-min performance in the fatigued state differently between groups (time x group p=0.26). However, relative mean power output during the 15-min fatigue test was improved by 6±4% in RP (Pre: 4.29±0.35 vs. Post: 4.54±0.32 W·kg-1, p=0.003), while a non-significant change of 4±5% was observed for NP (Pre: 4.26±0.44 vs. Post: 4.42±0.43 W·kg-1, p=0.06).

CONCLUSION: These preliminary data suggest that endurance athletes can reduce dietary protein to as low as ~1 g protein·kg-1·d-1 for 6 weeks without compromising lean body mass and overall performance, and potentially may induce improvements in performance in the fatigued state.

DATA PROCESSING STRATEGIES TO DETERMINE MAXIMUM OXYGEN UPTAKE: A SYSTEMATIC SCOPING REVIEW AND EXPERIMENTAL COMPARISON WITH GUIDELINES FOR REPORTING

NOLTE, S.1, REIN, R.2, QUITTMANN, O.J.1

GERMAN SPORT UNIVERSITY COLOGNE

INTRODUCTION: Gas exchange data from maximum oxygen uptake (VO2max) testing typically requires post-processing. Different processing strategies can lead to varying VO2max values [1]. This affects their interpretation particularly in situations where small differences in VO2max matter (e.g. training monitoring or clinical classification) [2]. However, the exact processing strategies used in the literature have not been systematically investigated yet [3]. Previous research investigated differences across methods at the group level only [1].

METHODS: Based on preregistered methods and code, we conducted a scoping review and an analysis of experimental data. Out of a random sample, we investigated 242 recently published articles which measured VO2max during ramp(-like) tests. Reported data processing methods and their rationale were extracted. We compared the most common processing strategies on a data set of 72 standardized running exercise tests in trained athletes.

RESULTS: Almost all of the included studies (94.2%) failed to provide a rationale for the particular strategy chosen and 44.2% did not report their data processing strategy at all. In those which reported their strategy, most studies (79.5%) used binned time averages to determine VO2max, with a minority using moving time (6.8%), moving breath (5.7%) or other averaging methods (8.0%). Despite previous recommendations [3], no study reported the use of digital filters. The processing strategies found in the literature can lead to median differences in VO2max of more than 5% (range 0-7%) with considerable variation at the individual level.

CONCLUSION: Data processing strategies have a meaningful impact on determining VO2max. Hence, we recommend to report the following seven relevant items: (1) metabolic cart model, (2) measurement mode, (3) analysis software, (4) preprocessing routine, (5) processing strategy type, (6) processing strategy parameters, (7) rationale for the processing. To improve reproducibility, we encourage authors to use available software solutions [5] and share their analysis code.

MODE MATTERS - ENDURANCE EXERCISE MODES INFLUENCE CHANGES IN EEG RESTING STATE BRAIN NETWORKS

BÜCHEL, D., TORVIK, P.O., LEHMANN, T., SANDBAKK, Ø., BAUMEISTER, J.
PADERBORN UNIVERSITY

INTRODUCTION: Acute bouts of exercise affect the organization of human brain networks transiently and can either improve or deteriorate neural processes underlying sports performance. Exercise intensity is regarded as a key variable in this interaction, since moderate to high intensities facilitate neural processing, while exhaustive exercise seems to impair these processes. Besides intensity, the sensorimotor demands of different exercise modes may further affect modulations of brain networks due to differences in sports-specific techniques or muscles involved. However, exercise mode is barely considered an additional moderator of acute exercise brain interactions. Therefore, this study aimed to explore the effect of exercise mode on transient changes in electroencephalography (EEG) resting state networks (RSNs) comparing running and cross-country (XC) skiing.

METHODS: Fifteen male and highly trained XC skiers (20.1+.6 years, 74.4+5.6 kg, 178.9+5.5 cm) participated in the study. All athletes performed an incremental treadmill test to obtain peak oxygen uptake (VO2peak) in running (65.3 ml/min/kg) and XC skiing (63.5 ml/min/kg). Based on the incremental test, each athlete performed another incremental treadmill protocol with continuous stages at 50, 70, and 90% of speed VO2peak in both modes. EEG resting state data was recorded once before and intermittently throughout the protocols after each stage. The reconstruction of brain graphs allowed for the computation of the small world index (SWI, network efficiency), clustering coefficient (CC, network segregation), and path length (PL, network integration) in the theta, alpha-1, and alpha-2 frequency bands. To compare physiological demands between modes, blood lactate concentration, heart rate, and Borg scale were assessed. Repeated measures ANOVA was applied to explore the modulatory effects of exercise intensity (protocol stages) and mode (running vs XC skiing) on RSN outcomes and physiological markers.

RESULTS: ANOVA revealed main effects of exercise intensity in the theta network which indicated modulations of SWI ($p < .001$), CC ($p < .001$), and PL ($p = .003$) following exercise at 90% of speed VO2peak for both modes. Further, main effects of mode on SWI ($p = .047$), CC ($p < .001$), and PL ($p = .031$) were observed in the alpha-2 network and indicated stronger modulations in network organization following XC skiing. Physiological outcomes were modulated by intensity solely and peaked after exhaustive exercise in both modes ($p < .001$).

CONCLUSION: The present study demonstrated that both exercise intensity and mode may affect transient modulations of brain networks after exercise. Exercise intensity seems to induce modulations in brain networks associated with attentional control. Additionally, exercise mode seems to induce modulations in brain networks related to task-related information processing. Further research is required to understand the modulatory role of exercise mode in the acute interaction between exercise and brain function.

CYCLING PERFORMANCE AFTER ACCUMULATED LOAD: DOES DURABILITY CHANGE DURING A CYCLING SEASON?

VOET, J.G.1, LAMBERTS, R.P.2, DE KONING, J.J.1, VAN ERP, T.2
[1] VRIJE UNIVERSITEIT AMSTERDAM [2] STELLENBOSCH UNIVERSITY

INTRODUCTION: Durability is the ability to produce high power outputs after accumulated load (at the end of a race), which has been shown to be an important success factor in professional road cycling [1-4]. Gross efficiency (GE), fat oxidation (FATox) and carbohydrate oxidation (CHOox) have been proposed as underlying physiological factors for durability, as changes have been shown to be related to a decrease in performance after accumulated load [5-7], although there is much debate about them. Therefore, the aim of this study is to investigate durability and the underlying physiological factors in semi-professional cyclists. Secondly, this study investigates how durability and certain physiological factors changed during a cycling season.

METHODS: In total, 16 semi-professional cyclists (10min PO: 379±22 W) visited the lab on 3 occasions: Start of pre-season (PRE), start of race season (START), and halfway into the race season (IN). Testing days included: a warm-up at 55% of VO2peak power at which GE, FATox and CHOox were determined, followed by a 1min and 10min time trial to measure power output (P1min, P10min). After 3hours of endurance training (31±5 KJ/kg) the same protocol was repeated to investigate the influence of accumulated load on performance (P1min and P10min) and physiological parameters (GE, FATox and CHOox). Differences between PRE vs START vs IN and fresh vs fatigued were investigated using a mixed-effects multilevel model. When significant ($p<0.05$) main effects occurred, Bonferroni post-hoc was executed for pairwise comparisons.

RESULTS: P1minfresh was significantly higher than P1minfatigued at PRE, START and IN, however, no differences between PRE, START and IN were found. P10minfresh did not differ from P10minfatigued on all occasions, however, both P10minfresh and P10minfatigued were lower at PRE compared to START and IN. CHOox (PRE and START) and GE (START) were lower in fatigued compared to fresh state, while FATox was higher in fatigued compared to fresh (PRE and START). In addition, GEfresh was higher at START and IN compared to PRE, while there was a decrease in FATOxfatigued from PRE and START to IN. Lastly, an increase from PRE to START in CHOoxfatigued and PRE to IN in GEfatigued and CHOoxfatigued was noted.

CONCLUSION: This is the first study investigating (the change in) power output, GE and substrate oxidation in fresh and fatigued state after accumulated load during a cycling season. Performance over short efforts (P1min) is affected by fatigue but doesn't improve from PRE to IN. Endurance capacity (P10min and GE) is not significantly affected by accumulated load, however, improves throughout the season (from PRE to IN). Also, substrate oxidation after accumulated load changes as FATox decreases while CHOox increases from PRE to IN.

PERFORMANCE UNDER PRESSURE: PHYSIOLOGICAL AND COGNITIVE RESPONSES TO HYPEROXIC EXERCISE IN SCUBA-DIVING

MÖLLER, F., JACOBI, E., HOFFMANN, U., VOGT, T.

GERMAN SPORT UNIVERSITY COLOGNE

INTRODUCTION: Hyperoxia reduces minute ventilation (VE), heart rate (HR), and blood lactate ([Lac-]) during exercise in normobaric settings1,2. In addition, hyperoxia and exercise are known to positively affect executive functions (EF) of cognition3,4. However, little is known about applied sports activities underwater, like SCUBA-diving, where the practical relevance is emphasized by elevated inspiratory oxygen pressures (PIO2) from water depth and used gas mixtures. Here, environmental factors, the sport-specific exercise modality of underwater fin-swimming (UFS), and breathing resistance from diving equipment might alter previous results. We hypothesized that the combined increase in exercise intensity and PIO2 would (I) reduce VE and (II) amplify a positive interaction between exercise intensity and EF performance.

METHODS: Based on a priori power analysis (f=0.5; Power 1-β=0.9), 15 experienced SCUBA-divers (age: 28±6.2; 5 female) performed 3×8min of UFS at individual exercise intensities of 25% (LOW), 45% (MOD), and 75% (vIG) heart rate reserve. This scenario was repeated on three separate days with altered oxygen fractions in the breathing gas, resulting in 29, 56, and 140kPa PIO2 at 4m water depth (double-blind). HR and VE were measured continuously. Post-exercise, an EF task on inhibitory control was conducted (100 stimuli), capillary blood taken, and breathing gas analysis performed. Two-way ANOVAs with repeated measures on the factor INTENSITY and GAS investigated differences in VE, [Lac-], end-tidal pressure of carbon dioxide PetCO2, and incompatible reaction times (RT) and accuracy (ACC) for EF.

RESULTS: VE was significantly lower during 140kPa PIO2 compared to 29kPa at MOD (p=0.006, d=0.437) and VIG (p=0.006, d=0.405), and during 56kPa compared to 29kPa at VIG (p=0.002, d=0.525) compared to air (GAS: p=0.004, η2P=0.356). [Lac-] and PetCO2 showed no effects. RTs, not ACC, were significantly faster after VIG compared to REST, LOW, and MOD (all p≤0.022), without effects for GAS.

CONCLUSION: VE was reduced by 8-10 % during MOD to VIG exercise only, while a ceiling can be assumed between 56 and 140kPa PIO2. Based on similar post-exercise [Lac-] and PetCO2 values (all p>0.669), but in contrast to studies with submerged bicycle exercise (-15% VE5), dampened chemoreceptor control rather than metabolic changes was suspected as a possible cause. Superior EF performance corresponds to elevated [Lac-]- levels6 and maintained cerebral oxygenation during severe exercise7. Findings emphasize sport-specific influence from exercise modality and capacity, affecting safety, planning, and training for underwater activities like SCUBA diving.

INFLUENCE OF USING INDIVIDUALIZED ERGONOMIC HANDLES ON UPPER LIMB KINEMATICS, NEUROMUSCULAR ACTIVITY AND PERCEIVED COMFORT, DURING SCULL ROWING.

ERTEL, G.N., PITTO, L., MORNIEUX, G., SIMON, F.R., GAUCHARD, G.C.

UNIVERSITÉ DE LORRAINE

INTRODUCTION: All the power generated by the rower is transmitted to the oars and water by the handles, resulting in significant mechanical stress on wrist, elbow and shoulder joints. This might explain the large injury rate of the upper limb, representing more than 60% of injuries in paddle sports. This could be linked to joint overuse (e.g. repetition of 1800 propulsive cycles per training session in rowing (1)). In addition, the use of the standard circular handle could increase the injury risk, since a circular handle with a generalized size is not optimal for a strong and simple gripping pattern (2). Also, discomfort could lead to a higher risk of injuries (3). The purpose of this study was to measure the impact of using individualized ergonomic handles on upper limb kinematics and neuromuscular activity and perceived comfort during rowing.

METHODS: Twelve elite rowers performed 250 meters runs in single scull at their own race stroke rate with three handle types: (a) standard circular handles, (b) ratio handles following a 1:1.25 diameter ratio with an irregular hexagon shape fitted to the hand length of the athlete (CareMoSim, Nancy, France) and (c) comfort handles with ratio handles optimized based on adequacy of the rowers (CareMoSim, Nancy, France). Rowers were equipped with surface EMG electrodes (Flexor carpi Ulnaris, Brachioradialis, Biceps brachii, Triceps brachii longus, posterior and anterior Deltoid), and inertial movement units on the left upper limb. Joint range of motion and EMG were calculated from the recorded data. A comfort scale was used after the test for each handle (3). Repeated measures ANOVAs and Statistical parametrical mapping (SPM) were performed.

RESULTS: SPM showed a significantly smaller amplitude pattern of wrist flexion-extension during the first and last third of the drive phase (p<0.001), and during the last half of the recovery phase (p<0.001) with both ratio and comfort handles compared to the standard handle. There was significantly less EMG activity of posterior Deltoid (p=0.01) and Triceps brachii longus (p=0.03) with the ratio handle. There was significantly more comfort with the ratio (p=0.04) and comfort (p<0.001) handles compared to regular handle.

CONCLUSION: Individualized handles increased comfort and decreased wrist flexion/extension amplitude suggesting less articular stress on the wrist. It also induces lesser neuromuscular stress on the shoulder with less recruitment of Deltoideus posterior and Triceps Brachii Longus. Greater comfort, and lesser stress may decrease injury risks. The ergonomic design of the handle allows the rower to precisely control his wrist due to a constant wrist position feedback provided by the hand-fitted shape, thus decreasing stress over the upper limb. Hand-casted handle may be the next step.

IS-MH03 Physical exercise as a therapeutic strategy

THE EFFECT OF EXERCISE TRAINING ON PERIPHERAL VASCULAR RESISTANCE AND BLOOD PRESSURE IN MEN AND WOMEN

HELLSTEN, Y.

UNIVERSITY OF COPENHAGEN

Essential hypertension is a major cause of cardiovascular events and premature death in the world. The condition is closely associated with arterial stiffness and a reduced ability to adequately regulate peripheral vascular tone. Skeletal muscle contributes importantly to systemic vascular resistance due to its proportionally large mass and relatively extensive vascular network. Vascular resistance in skeletal muscle is regulated by a balance between, on one hand, sympathetic constriction and circulating vasoconstrictors and, on the other hand locally formed vasodilators and mechanisms which inhibit the constrictive effect of sympathetic activity, so called functional sympatholysis.

It is well known that regular aerobic exercise training has multiple beneficial effects on the vasculature in skeletal muscle with profound effects on arterial blood pressure, in particular in individuals with hypertension. Vascular effects include enhanced arterial compliance, an increased balance between vasodilators and vasoconstrictors, a lowering of sympathetic activity and improved functional sympatholysis. The enhanced capacity for vasodilation with training involves several compounds of which nitric oxide and prostacyclin are known to be central. Their increased bioavailability is the result of an upregulation and activation of related proteins but occurs also through a reduction in oxidative stress.

Although both men and women present vascular adaptions to regular physical exercise, evidence suggest that there is a reduced and/or slower adaptive progress in postmenopausal women compared to age matched men and that this progress is particularly evident in women many years after menopause. The mechanisms underlying this effect remain to be unraveled but some possibilities will be addressed in this talk.

METABOLIC FLEXIBILITY WITH AGING: IMPACT OF PHYSICAL ACTIVITY

BROOKS, G.

UNIVERSITY OF CALIFORNIA

Metabolic Flexibility can be defined as the ability to switch among energy substrates depending on metabolic need and substrate availability. The key hypothesis is that fragmentation of the mitochondrial reticulum results in loss of muscle respiratory capacity, one result being loss of metabolic flexibility in aging. For this, a mixed model has been employed with results of studies on young and old, male and female NIA mice informing the course of human experimentation. The human experiment is to compare metabolic responses in physically active (trained) and inactive (sedentary) young men and women (21-35 yr.). Results are to be compared with those on older, trained and sedentary men and women (60-80 yr.). Before, during and after a 75 g Oral Glucose Tolerance Test (OGTT) volunteers receive primed continuous infusions of [13C]Bicarbonate, D2-Glucose, [3-13C]Lactate and D5-Glycerol. On mouse, heart and muscle 3-D microscopy will reveal presence of mitochondrial reticulum fragmentation and disruption of the mitochondrial lactate oxidation (mLOC) complex. On human subjects, muscle biopsies genomic analyses will be by RNAseq and single cell whole genome sequencing. Dr. Brooks will deliver first report on the role of mitochondrial fragmentation on loss of metabolic flexibility in aging.

MUSCLE AND FUNCTIONAL REPERCUSSIONS OF SICKLE CELL DISEASE: BENEFICIAL EFFECTS OF ENDURANCE TRAINING

MESSONNIER, L.

UNIVERSITÉ SAVOIE MONT BLANC

The fundamental challenge of physical exercise for sickle cell disease patients remained prevention of exercise-induced complications like vaso-occlusive crises, favoured by lactate accumulation-associated risks. Indeed, lactate accumulation i) is accompanied by acidosis, which, in turn, may promote hemoglobin S polymerization and red blood cell (RBC) sickling, ii) is related to exercise-related adrenaline secretion which activates muscle glycogenolysis but also cell adhesion, and iii) is primarily driven by sympathetic nervous system activation with also induces vasoconstriction. Sickling, cell adhesion and vasoconstriction are all major triggering factors of VOCs. Because moderate-intensity exercise avoids blood-lactate ac-

cumulation, a safe and potentially beneficial moderate endurance-exercise training program appeared conceivable for SCD patients. Therefore, a randomized-controlled trial including an 8-week personalized moderate-intensity endurance training programme on a cycle ergometer in adult patients without severe chronic complications has been implemented. No significant peripheral oxygen desaturation, blood lactate accumulation, or complications occurred, so that the proposed programme appeared safe. This programme also induced muscle microvascular, structural, energetic, and functional improvements. More specifically, muscle histological analysis highlighted microvascular benefits in the trained compared to the untrained patients, including increases in capillary density and functional exchange surface between muscle fibre and the adjacent capillaries. Endurance training also increased type I muscle fibre surface area and oxidative enzymes activity (citrate synthase; cytochrome c oxidase of type I fibres; complex IV of the respiratory chain). Concerning more integrative physiological parameters, respiratory exchange ratio, blood lactate concentration and rating of perceived exertion were all significantly lower at a given submaximal power output after training. Finally, trained patients improved their workload at the first lactate threshold and their metabolic flexibility compared to controls. In conclusion, an individually-tailored endurance exercise training can be considered as a possible strategy to counteract the skeletal muscle defects, and to improve muscle function and quality of life of patients with SCD. In addition, we recently observed that the muscle microvascular and structural remodeling observed in (male and female) patients with sickle cell disease included sex specificities. These specificities will be exposed. Finally, age-related disease progression on muscle energetics and function have been recently highlighted on the Townes model of sickle cell disease. This age-effect will be addressed during this symposium.

SPEED AND POWER IMPROVEMENTS DERIVED FROM HYPOXIC REPEATED-SPRINT TRAINING IN WORLD-CLASS SHORT-TRACK SPEED SKATERS ARE INFLUENCED BY THE ANAEROBIC SPEED RESERVE

BILLAUT, F.1, DEGUIRE, S.2, BIEUZEN, F.2

1 UNIVERSITÉ LAVAL, QUÉBEC, QC, CANADA; 2 INSTITUT NATIONAL DU SPORT DU QUÉBEC, MONTRÉAL, CANADA

INTRODUCTION: Short-track speed skaters with different physiological traits can be successful on the international stage. We aimed to investigate the ergogenic potential and transferability of cycling repeated-sprint training in hypoxia (RSH) on key performance indicators in world-class speed skaters with different physiological and race profiles.

METHODS: Fourteen national team short-track speed skaters (women, n=6; men, n=8), including World and Olympic champions and world cup performers, added RSH (FIO2 13.5%) to their training regime 3 times per week for 3 consecutive weeks. RSH was implemented immediately after specific ice training sessions to prolong metabolic stimulation. Testing included on- and off-ice evaluations, pre and 2- and 4-weeks post RSH. Skaters were classified based on their race profile (endurance, hybrid, sprinter) estimated from fuzzy cluster analysis of the anaerobic speed reserve (top speed – maximal aerobic speed). Due to the team heterogeneity in sexes and race profiles, control participants could not be used, and all athletes undertook RSH.

RESULTS: On-ice top speed measured during a 3-lap test improved in both males (0.8%, Cohen's effect size ES 0.63, p=0.03) and females (1.3%, ES 1.04, p=0.06) 2-weeks post. Concomitantly, males improved their peak power during a 7-s cycling sprint (5.1%, ES 0.39, p=0.04). These changes were not meaningful 4-weeks post. In males only, Wingate average power also improved 4-weeks post RSH (3.3%, ES 0.23, p=0.08). Training did not enhance indices of endurance capacity (maximal aerobic power and 27-lap time-trial time). Sub-analysis of race profiles suggested that endurance-type athletes benefited the most from RSH to improve on-ice top speed (ES 0.45 vs hybrid ES 0.32 vs sprinter ES 0.17).

CONCLUSION: Results demonstrate that cycling RSH can transfer into meaningful improvements on the ice that are associated with neuromuscular function and anaerobic capacity in world-class skaters. This RSH modality tended to benefit athletes with the smallest anaerobic speed reserve, which could be used to target athletes with the greatest chances of improvements.

COMPARATIVE ANALYSIS OF THE DIAGONAL STRIDE TECHNIQUE DURING ON-SNOW AND ROLLER-SKIING IN JUNIOR CROSS-COUNTRY SKIERS

MA, M., LIU, H., LONG, T.

BEIJING SPORT UNIVERSITY

INTRODUCTION: To investigate the similarities and differences of the Diagonal Stride (DS) technique during on-snow and roller-skiing in junior cross-country skiers by three-dimensional video analysis. The results of this study provide a theoretical basis for the design of DS technique training and supplementary training for junior athletes on land.

METHODS: Six junior cross-country skiers participated in the experiment. The kinematic data of the DS technique on snow and land were obtained by three-dimensional video analysis. Two cameras were placed on the left and right sides of the test ramp. The Angle between the main optical axis is about 80°, the shooting frequency is 60fps, and the shutter speed is 1/500s. Athletes techniques were obtained using automatic recognition techniques and Direct Linear Transfor▪mation(DLT)

methods. The coefficient of multiple correlations (CMCs) and one-dimensional statistical parametric mapping (SPM1d) were used to evaluate the similarity and difference in angle-time curves for each stage of the DS technique for on-snow and roller-skiing. Paired sample T-test was used to compare the cycle characteristics, range of motion at each stage, and the angle at each moment of DS technique between on-snow and roller-skiing.

RESULTS: No significant difference in roller-skiing cycle characteristics compared to on-snow in DS technique. The hip flexion and extension angles are highly similar and the body anteversion angle, trunk anteversion angle, calf anteversion angle, and the vertical movement range of the center of the mass showed moderate similarity in the landing stage and the swing stage; The adduction and abduction angle of the hip joint showed low similarity in the swing stage, the body anteversion angle and calf anteversion angle are smaller on roller-skiing and the anteversion angle is smaller on roller taking off. The flexion and extension angle of the shoulder joint, the adduction angle of the shoulder joint, the flexion and extension angle of the elbow joint, the angle of pole-ground, and the vertical movement range of the center of mass show high similarity in the poles-support stage and the back-swing stage; The body anteversion angle in the poles-support stage and the trunk anteversion angle in the back-swinging stage are moderately similar; The range of flexion and extension of the shoulder joint is small in the back-swinging stage, and the body anteversion angle and trunk anteversion angle are small at poles landing and taking off.

CONCLUSION: Higher similarity of upper limb movements, the moderate similarity of lower limb movements between on-snow and roller-skiing with DS technique, and the movement range of the DS technique on land are small. Junior athletes should imitate fast kick in the kick zone of the ski when training DS technique on the roller, and increase the explosive power of the lower extremity, especially the explosive power of plantarflexion, as well as upper extremity extensor strength.

EFFECTS OF POSTURE ON THE AERODYNAMIC CHARACTERISTICS DURING TAKE-OFF IN SKI JUMPING

HU, Q.

CHINA INSTITUTE OF SPORT SCIENCE

INTRODUCTION: From an aerodynamic perspective, take-off phase is very critical because athletes always need to find a balance between maximizing vertical acceleration and minimizing aerodynamic drag. Rapid full exposure to the air during take-off leads to a rapid increase in the aerodynamic drag, while the aerodynamic lift helps the athlete during the take-off process. The research on the aerodynamic characteristics of take-off phase mainly focuses on the experimental test and training in the wind tunnel, or the analysis from the perspective of kinematics, but the aerodynamic force during take-off is still unclear, and few related computational fluid dynamics (CFD) studies are reported.

Rapid full exposure to the air during take-off leads to a rapid increase in the aerodynamic drag, while the aerodynamic lift helps the athlete during the take-off process. The research on the aerodynamic characteristics of take-off phase mainly focuses on the experimental test and training in the wind tunnel, or the analysis from the perspective of kinematics, but the aerodynamic force during take-off is still unclear, and few related computational fluid dynamics (CFD) studies are reported.

RESULTS: 1) For take-off mode A, the initial total drag is 40.20N and the final total drag is 99.05N; the initial total lift is 31.31N and the final total lift is 53.58N; the initial moment is 19.69N·m and the final moment is 69.05N·m; the lift-to-drag ratio drops from 0.779 to 0.541.For take-off mode B, the initial total drag is 50.66N and the final total drag is 140.01N; the initial total lift is 35.56N and the total lift peak is 55.54N; the initial moment is 28.06N·m and the final moment is 98.82N·m; the lift-to-drag ratio drops from 0.702 to 0.365. 2) The total drag and moment of take-off mode B are significantly higher than that of take-off mode A, and the lift-to-drag ratio of take-off mode B is significantly lower than that of take-off mode A. 3) At first the total lift of take-off mode B is higher than that of take-off mode A, but in the last attitude the total lift of take-off mode B does not rise but fall, and finally the total lift of the take-off mode B is lower than the take-off mode A .

CONCLUSION: 1) The aerodynamic characteristics change dynamically in a short time, and the two take-off modes differ greatly, which are difficult to be observed in real training and competition site. 2) Take-off mode A has obvious aerodynamic advantage compared with take-off mode B. During take-off, the angle between trunk and thigh should not be too large, or the extension angle of the hip joint should not be too fast and too large, which can bring obvious aerodynamic advantage. 3) Although the aerodynamic force of arms themselves is not obvious, they have a huge impact on the overall aerodynamic characteristics of the athlete, so the posture of arms cannot be ignored. 4) The influence mechanism of different take-off postures on the aerodynamic characteristics in ski jumping can provide scientific guidance for the training and improvement of jumping and flight technology, and also provide effective auxiliary support for on-the-spot prediction and decision-making.

DOES TRUNK RANGE OF MOTION DURING SITTING PARA CROSS-COUNTRY SKIING DIFFER BETWEEN CLASSES?

SEVERIN, A.C., BAUMGART, J.K., KOCBACH, J.

NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY

INTRODUCTION: In sitting Para cross-country (XC) skiing, athletes compete in a seated position and thus rely predominantly on their arms and trunk for propulsion [1]. Double poling at higher work rates requires increased trunk motions [2], and it is likely that the trunk function of Para sit-skiers will influence their ability to produce high power output [3] and speeds. The classification of sitting XC-skiers is based on clinical trunk function tests, and athletes with higher trunk func-

tion are often allocated to higher classes. However, it is difficult to accurately estimate the functional trunk range of motion (ROM) of an athlete during sit-skiing based on these assessments. Modern inertial measurement unit (IMU) technology allows the estimation of the trunk ROM during on-snow competitions. This study therefore aimed at comparing the trunk ROM between classes of sitting para-XC skiers during competition.

METHODS: A single IMU sensor (AdMos, ASI, Lausanne, Switzerland) was attached to the back of the race bib of 22 sitting para XC-skiers during a sprint race at a World Championship competition (9F, 13M, LW10=1, LW10.5=4, LW11=3, LW11.5=9, LW12=9). The IMU was placed between the scapulae and recorded gyroscope and accelerometer data at 200Hz, which was processed in Matlab (R2022b, MathWorks, Natick, MA, USA) to calculate joint angles. Data from the final 70-meter stretch of the race was extracted for analysis. Due to the low number of athletes in each class, the data was solely assessed descriptively. The differences in trunk ROM between classes were assessed by comparing the 95% Confidence Intervals (CI) around the mean. When these showed no overlap, it indicated 95% confidence of a difference between means.

RESULTS: Since the dataset only had one LW10, this data point was excluded from the comparison (ROM: 6.3°). The 95%CI did not overlap for the comparison between the LW10.5 and LW12 classes (mean ROM ±95%CI: LW10.5 12.4°±6.4°, LW12: 28.7°±5.9°). The other comparisons had overlapping CI and quite a large variability in ROM (mean ROM ±95%CI: LW11: 25.6°±31.1°, LW11.5: 19.8°±14.0°).

CONCLUSION: While we see a tendency towards larger functional trunk ROM in the higher classes, the 95%CI overlapped for all comparisons except for LW10.5 vs LW12. This overlap between adjacent classes, and in some cases also classes further apart suggests that the clinical assessment used in classification may sometimes fail to adequately identify the amount of trunk function a sit-skier uses during competition. The extent to which the functional trunk ROM differs between the classes remains unknown and should be subject to further research. This study suggests that assessing the functional trunk ROM alone may not provide sufficient information to differentiate between the classes during para sit-skiing.

V2 CROSS-COUNTRY SKIING TECHNIQUE VARIATIONS ASSESSED THROUGH PRINCIPAL MOVEMENT DISCRIMINANTS EXTRACTED FROM WEARABLE SENSOR DATA

DEBERTIN, D.

UNIVERSITY OF INNSBRUCK

INTRODUCTION: Cross-country (XC) skiing experts (instructors, coaches) describe precise technique forms, e.g. V2 technique, and distinct variation/deviation patterns from the technique ideal. These qualitative decriptions have high practical value, e.g. for the communication between coach and athlete, however, they are difficult to quantify, limiting their applicability for research or technology development. The current study utilizes and expands technique analysis approaches based on principal component analysis of kinematic data [1,2] and applies them to analyse V2 technique variations in XC skiing. The aim of this proof-of-concept study was to determine sensitivity for 14 distinct V2 technique variations.

METHODS: Ten experienced XC skiers (5 females, age 30±8y, national or FIS licenced as instructor or athlete) performed the V2 technique according to curriculum guidelines [3] and according to 14 technique variations, each represented through two opposite extremes: weight shift (forth/back, up/down, lateral/centered), inward/outward upper body rotation, closed/opened legs, flat/canted ski strike, flat/canted ski off, long/short gliding phase, raised/lowered head, lowered/lifted heel, highly extended/flexed elbows, lowered/lifted elbows, maximal/minimal arm swing, closed/opened hands. The skiers' body segment movements were recorded using a full-body wearable sensor system (Xsens, Enschede, NL; 240Hz). For each technique variation, a principal component analysis (PCA) was calculated on centered and normalized kinematic data yielding principal movements (PMs) [2] that were dominanted by the variance produced by the two opposite variation extremes. Three left-right step cycle sequences were extracted and then averaged for each subject. These averaged PM scores were normal distributed (Shapiro-Wilk) and effects of the technique variation (3 levels: extreme(-); guideline V2 technique; extreme(+)) could therefore be tested using rmANOVAS (a=.05). Sensitivity was quantified through effect sizes (np2).

RESULTS: Eleven out of the 14 technique variations showed significant differences in their waveform means, with the largest effects found for horizontal weight shift (np2= .906), arm swing (np2 = .803) and elbow flexion/extension (np2 = .785).

CONCLUSION: The current study proved sensitivity for 11 of 14 distinct technique variation/deviation patterns. The three variations for which our approach was not sensitive included variations for which a more sofisticated analysis might be promising, but also variations poorly represented in the current sensory signals (e.g. raised/lowered head) for which hardware adaptations might be needed. In conclusion, our approach utilizes the knowledge and skills of skiing experts and makes them accessible for research and technology development.

INVESTIGATION OF FALSE POSITIVE RESULTS IN ANTI-DOPING TEST CAUSED BY PRESERVATIVES IN COSMETICS

LU, Y.W.1, CHAN, K.H.2,3, WU, Y.T.1, CHANG, W.C.W.1

SCHOOL OF PHARMACY, KAOHSIUNG MEDICAL UNIVERSITY 1, GRADUATE INSTITUTE OF ATHLETICS AND COACHING SCIENCE, NATIONAL TAIWAN SPORT UNIVERSITY 2, CHINESE TAIPEI ANTI-DOPING AGENCY 3

INTRODUCTION: Chlorphenesin is a legitimate preservative used in cosmetics. Chlorphenesin shares the same urinary metabolite of 4-chlorophenoxy acetic acid (4-CPA) with a stimulant meclofenoxate which is prohibited in sports. In recent years, there have been several cases involving athletes who used chlorphenesin-containing products were misjudged as using meclofenoxate. To distinguish the origins of 4-CPA from using chlorphenesin or meclofenoxate, we investigate the content of personal care products on the market and perform an administration study to confirm whether using chlorphenesin-containing products can lead to an adverse analytical finding (AAF) or not.

METHODS: We selected personal care products with different functions (e.g. facial care, body cleansing, sun protection, make-up, hairstyling, perfume and oral cleaning) on the market. These cosmetics were detected for chlorphenesin by using the developed liquid chromatography with diode-array detection (LC-DAD) method. To further investigate the metabolic pattern after applying chlorphenesin-containing cosmetics, we established a liquid chromatography-tandem mass spectrometry (LC-MS/MS) method for the quantification of 4-CPA and related metabolites in urine.

RESULTS: A total of 61 personal care products were tested. Among all, there were 29 labeled as containing chlorphenesin, and their concentrations ranged from not detected (ND) to 2.67 μg/mg (0.267 %). Chlorphenesin was not detected in the 32 items unlabeled with chlorphenesin. The LC-MS/MS method successfully achieved mass transitions of the target analyte by optimizing the parameters for ionization, fragmentation, and MRM detection. The accurate mass of the precursor ion (m/z 184.85) and product ions (m/z 140.85 and 126.86) was confirmed for 4-CPA analysis. In the proof-of-concept study, participants applied chlorphenesin-containing products and the concentrations of 4-CPA in their urine were measured.

CONCLUSION: The detection of chlorphenesin in cosmetics did not exceed the limit of 0.3 % (3 μg/mg), which was in accordance with Taiwanese regulations. According to the World Anti-Doping Agency (WADA) Technical Document, the urinary concentration of 4-CPA exceeding 5 μg/mL may be considered as an AAF. Therefore, it is inferred that single or multiple doses of chlorphenesin-containing products may result in 4-CPA higher than the threshold. The present study can support sports drug testing to identify the sources of 4-CPA and assist in the results management process.

NON-INVASIVELY MEASURED CENTRAL AND PERIPHERAL FACTORS OF OXYGEN UPTAKE ARE AFFECTED BY AGE, SEX, ENDURANCE CAPACITY, AND CHRONIC HEART FAILURE

BROCHHAGEN, J.1, COLL BARROSO, M.T.2, BAUMGART, C.3, WASMUS, D.T.1, FREIWALD, J.3, HOPPE, M.W.1

1 LEIPZIG UNIVERSITY, GERMANY; 2 UNIVERSITY OF WITTEN/HERDECKE, GERMANY; 3 UNIVERSITY OF WUPPERTAL, GERMANY

INTRODUCTION: Maximum oxygen uptake is influenced by age, sex, endurance capacity, and chronic heart failure. However, underlying central and peripheral factors are essential to take into account for optimizing diagnostics and interventions in athletes and patients [1, 2], but are less studied due to the in part invasive approaches. This study aimed to investigate the effects of age, sex, endurance capacity, and chronic heart failure on non-invasively measured central and peripheral factors of oxygen uptake.

METHODS: 15 male children (11±0 years), 15 male recreationally active adults (24±1 years), 14 female recreationally active adults (23±1 years), 12 male highly trained endurance athletes (24±2 years), 10 male elders (59±3 years), and 10 male chronic heart failure patients (62±4 years) were tested during a cardiopulmonary exercise test until exhaustion on a cycling ergometer for: oxygen uptake, systolic blood pressure, diastolic blood pressure, mean arterial pressure, heart rate, stroke volume, cardiac output, cardiac power output, vastus lateralis muscle oxygen saturation, and (calculated) arterio-venous oxygen difference. Stroke volume and muscle oxygen saturation were measured non-invasively using bioreactance analysis and near-infrared spectroscopy, respectively. A two-factor repeated measure ANOVA was applied for statistical analyses at rest, 80, and 100% of maximum oxygen uptake.

RESULTS: For the age effect, there were statistically significant group differences for all factors ($p \leq .033$; ES:≥.169). Concerning sex, there were group differences for all factors ($p \leq .010$; ES:≥.223), except diastolic blood pressure and heart rate ($p \geq .698$; ES:≤.006). For the effect of endurance capacity, there were no group differences for any of the factors ($p \geq .065$), albeit up to medium effect sizes (ES:≤.129). Regarding chronic heart failure, there were group differences for the heart rate and arterio-venous oxygen difference ($p \leq .037$; ES:≥.220).

CONCLUSION: Non-invasively measured central and peripheral factors of oxygen uptake are affected by age, sex, endurance capacity, and chronic heart failure. The detected differences may be due to various morphological or physiologi-

cal reasons, particularly heart volume or myoglobin functions [3, 4], which however remain unknown. Our outcomes should serve as a basis for further studies in sport science and medicine.

EFFECTS OF CONCURRENT, WITHIN-SESSION, AEROBIC AND RESISTANCE EXERCISE TRAINING ON FUNCTIONAL CAPACITY AND MUSCLE PERFORMANCE IN PATIENTS WITH CHRONIC HEART FAILURE

IELLAMO, F.1, CAMINITI, G.2, PERRONE, M.A.1, MANZI, V.3, VOLTERRANI, M.2

1 UNIVERSITY TOR VERGATA, ROME; 2 IRCCS SAN RAFFAELE PISANA, ROME; 3 TELEMATIC UNIVERSITY PEGASO, NAPLES

INTRODUCTION: The best format of exercise training (ET) in the setting of cardiac rehabilitation in patients with chronic heart failure (CHF) is still to be defined. Current guidelines recommend aerobic exercises, such as running and cycling including some sessions per week of resistance exercise. The aim of this study was to address the effectiveness of a concurrent exercise training program utilizing a circuit of sequential endurance and resistance exercises on functional capacity and muscular strength in patients with CHF.

METHODS: Ninety-five consecutive male patients with CHF (EF<40%) in NYHA functional class II /III, with were randomly assigned on 1:1 basis to a 12-week aerobic continuous training (AT) or concurrent CT), aerobic + resistance, training (CT), three times a week, with each session lasting 80 minutes. We used high quality, specifically designed, ergometers, connected one each other and governed by a central consol, managed by a single physiotherapist. Before and after training all patients performed a symptoms-limited exercise test on a treadmill and a 6-min walking test (6MWT). Patients in the CT group also performed resistance exercises of the upper and lower body.

RESULTS: 6MWT and exercise duration at ergometric test increased significantly in both AT and CT groups, with the increase being greater in CT group (P<0.001; ES = 0.13; P<0.01; ES = 0.07). Muscular strength increased significantly in the CT group, particularly in the-lower body muscular districts (P<0.001). Quality of life improved in both groups, with a significantly greater improvement in the CT group (P< 0.05). No side effects leading to discontinuation of training were observed.

CONCLUSION: These findings indicate that concurrent, within-session. training results in larger improvements in functional capacity, in addition to muscle performance, in patients with CHF in comparison to single-mode aerobic training.

RETINAL LAYERS PARAMETERS ASSESSMENT AS BIOMARKERS AFTER RUGBYMEN'S HEAD TRAUMA

BONNIN, S., BLANCHARD, S., AZAR, G., VINCENT, Q., LAFOLIE, J., ALONSO, A.S., THÉVENIN, S., SALVIAT, F., MAUGET, M., VASSEUR, V.

ROTHSCHILD FOUNDATION HOSPITAL

INTRODUCTION: The consequences of mild traumatic brain injures and sports-related concussions are a challenge for clinicians, players, coaches and parents involved in contact sports. Retinal layers' changes have been reported in numerous neurodegenerative diseases. The aim of this study was to investigate longitudinally the retinal thickness changes and their association with concussion during one rugby season in professional rugbymen, using spectral domain (SD) - optical coherence tomography (OCT).

METHODS: This is a longitudinal prospective cohort study. All patients were members of the Racing 92 rugby team (Paris, France). The first ophthalmological visit was performed before the beginning of the season, then a second visit was planned the following year just before the beginning of the next season. During the season, participants were closely followed by the teams' medical staff and the number of concussions was reported. At each ophthalmological examination, all participants had SD-OCT and OCT-angiography, which allowed the measurement of peripapillary and macular thicknesses.

RESULTS: Among the 59 rugbymen included at baseline, 36 were followed during one year and had one final visit after the season. Mean Retinal Nerve Fiber Layer (RNFL) thickness decreased significantly between the initial and the final visit (102.65 ± 7.01 µm vs. 101.46 ± 7.14 µm, p=0.0001). There was also a significant decrease of the mean ganglion cell layer (GCL) volume (1.16 ± 0.08 mm3 vs. 1.14 ± 0.09 mm3, p<0.0001) and of the mean macular vascular density (19.71 ± 3.01 % vs. 19.36 ± 3.03 %, p = 0.0002).

Among those 36 patients, 5 (13.9%) suffered from at least one concussion during the follow up. Mean RNFL loss was significantly higher in rugbymen who had at least one concussion during the follow up (n=5, -3.9 □ 1 µm) in comparison with those who had no concussion (n=31, -0.8 □ 1.2 µm) (p = 0.0008). No correlation was found between the number of concussions and the position of the rugbyman in the team.

CONCLUSION: RNFL loss was significant in professional rugbymen, after only one season time, and was significantly higher in concussion group, showing the interest of SD-OCT in the assessment of head traumas' consequences in rugby-

men. OCT RNFL monitoring could be helpful for the management of concussions in rugbymen. Further longitudinal studies are still needed to determine which level of RNFL loss should be a recommendation of sport cessation.

PHYSICAL ACTIVITY AND VENTRICULAR TACHYCARDIA IN PATIENTS WITH ARRHYTHMOGENIC CARDIOMYOPATHY

SORIANO-MALDONADO, A., RAMOS-MAQUEDA, J., MIGUELES, J.H., MOLINA-JIMÉNEZ, M., RUIZ-GONZÁLEZ, D., JIMENEZ-JAIMEZ, J.

UNIVERSITY OF ALMERÍA

INTRODUCTION: The aim of this study was to investigate the association of accelerometer-measured lifestyle physical activity with rapid-rate non-sustained ventricular tachycardias (RR-NSVTs) in patients with arrhythmogenic cardiomyopathy (AC).

METHODS: This multicenter, observational study enrolled 72 patients with AC (recruited from two Spanish hospitals), including right, left-, and biventricular forms of the disease, with underlying desmosomal and non-desmosomal mutations. Lifestyle physical activity was objectively and continuously monitored for 30 consecutive days with accelerometers (Axivity AX3, OmGui, Newcastle University). To evaluate the occurrence of RR-NSVTs, the participants were required to wear a textile Holter electrocardiogram (Holter Nuubo ECG PLATFORM®) for 30 consecutive days. A RR-NSVTs was identified as having a heart rate >188 bpm for >18 beats and were confirmed by an independent electrophysiologist blinded to the patients' medical history and the level of physical activity.

RESULTS: Sixty-three AC patients (38±17.6 years, 57% men) had valid data for both devices and were included in the analyses. A total of 17 patients experienced ≥1 RR-NSVTs, and a total of 35 events were recorded. The odds of occurrence of ≥1 RR-NSVT during the recording did not increase as a function of either total physical activity (OR=0.95, 95% confidence interval [CI 95%]=0.68-1.30 for 60-min increase) or moderate-to-vigorous activities (OR=0.89, CI 95%=0.71-1.08 for 5-min increase). Participants presenting RR-NSVTs during the recording (n=17) did not present greater odds of RR-NSVT in the days with more time either in total physical activity (OR=1.05, CI 95%=0.84-1.29 for 60-min increase) or moderate-to-vigorous activities (OR=1.05, CI95%=0.97-1.12 for 5-min increase). Physical activity levels were neither different between the patients with and without RR-NSVTs during the recording period nor on the days of the occurrence of RR-NSVT compared with the rest of the days. Finally, 4 of the 35 RR-NSVTs recorded in the 30 days occurred during physical activity (3 during moderate-to-vigorous intensity and 1 during light-intensity activities).

CONCLUSION: The main findings of this study suggest that lifestyle physical activity is not associated with RR-NSVTs in AC patients. Therefore, this study supports the notion that lifestyle physical activity of light and moderate intensity could be promoted among AC patients to ensure they obtain the multiple benefits associated with physical activity.

PERFORMANCE PROFILE IN INTERNATIONAL MALE 3X3 BASKETBALL, REGARDING LIVE-STOPPAGE TIME RATIO AND GAME TIME

HAUER, R.1, SCHARNER, P.2, MATHY, A.1, BACA, A.2, TRISKA, C.1

1LEISTUNGSSPORT AUSTRIA, 2UNIVERSITY OF VIENNA

INTRODUCTION: 3x3 basketball is a novel sports discipline and merely a paucity of evidence on the physical demands is available. Only few studies deal with live- (LT) & stoppage-time (ST) and the ratio of these parameters, which could be useful for coaches to design appropriate and close-game training sessions [1]. Therefore, the aim of this study was to analyze LT and ST in relation to the dynamics of the game.

METHODS: Fifteen international male 3x3 basketball games were analyzed using a video analyze system. For each game LT and ST were tagged and categorized into five phase (ph) durations: ph-I: 1-10s; ph-II: 11-20s; ph-III: 21-30s; ph-IV: 31-40s; ph-V: >40s. Time intervals (TI) were defined to subdivide the game: first 5min (t1), 5-10min (t2), last 3min (t3).

A repeated measures ANOVA was used to detect differences between the number and duration of LT and ST as well as effect size expressed as partial eta-squared (ηp^2). Significant main effects were followed-up by Bonferroni post-hoc procedures. Significance was set at $P<0.05$.

RESULTS: Mean±SD of all actions and rest periods per game were 28±5 each. The total time ratio between LT and ST was 0.92±0.22.

Actions in ph-I accounted 42% of all actions (ph-II: 23%, ph-III: 15%, ph-IV: 9%, ph-V: 11%). Significant differences were found in the number of all actions between TI ($P\leq0.001$; ηp^2=0.748). Observed number of actions in t1 were 9±1, t2: 6±1 and t3: 3±1. Post-hoc test revealed differences between all TI with a significance of $P\leq0.004$.

Rest periods lasting for 11-20s accounted 53% of all breaks (ph-I: 11%, ph-III: 11%, ph-IV:10%, ph-V: 14%). The distribution of LT and ST for the entire game is also reflected in all TI (t1-t3). Significant differences were found regarding the number of rest periods in relation to the TI ($P\leq0.001$; ηp^2=0.690). The number of rest periods in t1 were 8±1, t2: 7±1 and t3: 4±1. Post-hoc test revealed differences between all TI with a significance of $P\leq0.038$.

Mean duration of LT was 20.0±3.7s and of ST 22.0±1.9s. Significant differences were only found in ST regarding to the TI (P=0.023; ηp^2=0.280). The duration of ST in t1 were 18.3±4.1s, t2: 30.9±15.0s, and t3: 24.8±7.3s. Post-hoc test revealed differences between t1&t2 (P=0.018) and t1&t3 (P=0.042) with no differences between t2&t3. No significant differences were found regarding the duration of LT.

CONCLUSION: T1 showed significantly higher numbers of actions and breaks compared to t2 and t3. Furthermore, rest duration was highest in t2, which could be caused by external influenced breaks (e.g.: TV time-out). Even if the total LT duration is 20.0s, almost half of the actions last for ≤10s only. In summary, results of this study suggest that game dynamic seems to change over the course of time. This should be considered for technical and tactical competition preparation by the coaching staff.

THE MOMENTARY EFFECT OF TIMEOUTS IN NATIONAL BASKETBALL ASSOCIATION GAMES

CHEN, C., CAO, R., CUI, Y.

BEIJING SPORT UNIVERSITY

INTRODUCTION: During competitive basketball matches, coaches are expected to optimize the collective performance throughout effective decision-making, including calling timeouts, devising player rotation and rearranging tactics. Previous studies have demonstrated that teams usually presented better scoring performance after coaches' substitutions and their decisions were influenced by multifactorial competition constraints. In this vein, this study aimed to quantify the temporal effects of the timeouts during professional basketball matches, so as to evaluate the performance of coaches' decision-making and to provide insights into player management and match status anticipation.

METHODS: Play-by-play and spatio-temporal data from 100 NBA games during the 2015-2016 season provided by STATS LLC were used, with 1155 timeouts being identified and extracted. The temporal effects that timeout may have on scoring performance were analysed using the points scored and received within the previous and post 5 ball possessions. The analysis included the following performance indicators: rebounds, fouls, turnovers, free throws, 2-point and 3-point field goals; contextual indicators: point difference, location, timeout type, and period; and spatio-temporal indicators: team run distance and average speed. For each category, the indicators were calculated as the difference between two teams. After normalizing the data, a stepwise multiple linear regression model was established to explore the relationship between the timeout effect and indicator variables, with the teams points difference as the dependent variable.

RESULTS: After considering a total of 10 independent variables above, the model was obtained after 5 steps of modeling, 4 variables were excluded. The model obtained is y= -0.075+0.167*period+0.324*rebounds-0.316*turnovers+0.181*free throws+0.112*fouls-0.055*team run distance (adjusted R-squared: 0.200, p<0.05). During 5 ball possessions, team run distance showed significant negative effect for the timeout (p=0.04). For the dummy variable of period, the coefficient of the 4th period is 0.167 (p=0.023), while the other periods had no statistically significant effect for the timeout (p>0.05).

CONCLUSION: The results showed that calling a timeout in the 4th period positively affects rebounds, free-throws, and fouls, possibly due to increased pressure and fatigue in this crucial period of the game. Also, it is important for teams to focus on minimizing turnovers in order to improve overall performance. Nevertheless, team run distance had a negative relationship of timeout effect in this model, which was probably due to the fact that coaches tend to call timeouts to modify team tactics. This could lead to a decrease in overall team run distance as players move deliberately to execute specific plays. In conclusion, the study provides novel insights for assessing timeout effectiveness and emphasizes the need to consider multiple factors when evaluating coaches decision-making performance.

EXPLORING SUCCESS OF FOUR LIQUI-MOLY HANDBALL BUNDESLIGA TEAMS FROM 2019 TO 2022

SAAL, C.1, ACKERMANN, N.1, WEGENER, F.1, SÖLTER, F.2, BAUMGART, C.3, HOPPE, M.1

1UNIVERSITY LEIPZIG, 2MT MELSUNGEN, 3UNIVERSITY OF WUPPERTAL

INTRODUCTION: Handball is a contact team-sport with the objective to score more goals than the opponent. Knowledge about the match demands and their relation to playing success are crucial to optimizing training procedures. Previous studies show that running related demands do not differ with respect to the match outcome [1], while other studies found differences between winning and losing teams [2]. Thus, the aim of this study was to explore match demands in relation to the team and match outcome in top-level handball players.

METHODS: Four handball teams competing over three seasons (2019-2022) in the LIQUI-MOLY Handball-Bundesliga (HBL) were compared and analyzed according the match outcome using a range of common match demand metrics (n = 28) collected by a local positioning system (Kinexon Perform LPS). Match summary statistic files (n = 371, n=228 with ball tracking) were exported using the Kinexon software and merged with the match outcome data. Mean differences were investigated by one-way ANOVAs on trimmed means. Pairwise comparisons were conducted and p-values were adjusted for multiple testing by Bonferroni corrections.

RESULTS: The lower ranked teams spent less time at high-speed (-89.9 [-140.0, -48.9]; -132.5 [171.5, -93.4]) and high metabolic power (-86.4 [-123.9, -48.9]; -73 [-220.0, -139.4];-179.8 [-220.1, -139.5]), whereas they executed a higher number of jumps (16.7 [9.8, 23.6]; 8.0 [2.0, 13.9]) and passes (168.6 [123.3, 213.9]; 97.2 [47.7, 146.7]; 105.3 [53.4, 157.2]). Winning teams perform slightly less passes (-51.2 [-101.2, -1.14]; -28.4 [-67.6, 10.7]) than drawing teams and show no differences in

time at high-speed (29.1 [-25.3, 83.5]; 10.7 [-18.3, 39.8]) and time at high metabolic power (21.0 [-42.3, 84.5]; -24.6 [-55.4, 6.1]) than drawing or losing teams.

CONCLUSION: The lower ranked teams spent less time in high-intensity running and perform more passes. In this context, winning teams tend to perform less passes, but do not differ between drawing and losing teams in terms of high-intensity running. These findings provide a new perspective of the influence of match demands on success in top-level handball. It underlines that the players are all "physically well developed" [2] and therefore we hypotheses that technical-tactical actions are more important to win a game at this level. However, more studies that include the technical-tactical context to explain success in top-level handball are needed.

OPTIMISING THE USE OF MACHINE LEARNING AND COMPUTER VISION IN SPORT: AN ECOLOGICAL DYNAMICS PERSPECTIVE

AULTON, C., STRAFFORD, B., DAVIDS, K., CHIU, C.

SHEFFIELD HALLAM UNIVERSITY

INTRODUCTION: Machine learning and computer vision technology is a growing area of research aimed at improving athlete development and performance, but the use of machine learning and computer vision in athlete development programs does not guarantee an improvement in athletic performance (5). Computer scientists typically design and implement machine learning and computer vision technology into athlete development programs because of the high level of technical knowledge required. This approach can lead to siloed working and sporadic approaches to athlete development which can negatively impact skill development [1, 2]. The integration of machine learning and computer vision in athlete development programs need to be rationalised to allow practitioners to collaborate effectively and avoid siloed working to maximise its potential within athlete development programs. Currently there has been no attempt to contextualise the applications of these technologies.

METHODS: In this study, pervious literatures were reviewed to show that the development of an ecological dynamics and Department of Methodology pillared framework is necessary to support the application of machine learning and computer vision into athlete development programs. A pillared ecological framework including the Department of Methodology was then developed.

RESULTS: This study suggests that the transdisciplinary approach of the Department of Methodology can allow practitioners to collaborate effectively through shared principles and language under the rubric of ecological dynamics to create information rich practice environments enriched with machine learning and computer vision. Machine learning and computer vision techniques can improve the quality of athlete development programs by improving perceptual information within virtual environments (6), predict overuse injuries (4) and provide coaches highly detailed data to increase the quality of coaching feedback. To fully utilise machine learning and computer vision technology within athlete development programs collaboration between sub-disciplines of sport and computer science is essential. The ecological pillared framework developed can also support the need for a more embodied and embedded application of machine learning and computer vision in sport [1].

CONCLUSION: This study provides practitioners with an ecological dynamics and Department of Methodology pillared framework to enhance athlete development programs through the implementation of collaboratively designed machine learning and computer vision technology. This study also demonstrates how an ecological pillared framework can improve the representative learning design, promote an individualised approach and enhance but not replace the quality of coaching feedback through the application of machine learning and computer vision technology.

SMART BOXING GLOVE: TECHNIQUE AND TARGET RECOGNITION USING MACHINE LEARNING

CIZMIC, D., HOELBLING, D., LICHTMANNEGGER, C., BREITENEDER, R., BARNANYI, R., GRECHENIG, T.

VIENNA UNIVERSITY OF TECHNOLOGY

INTRODUCTION: Novel technologies, such as the smart boxing gloves establish new ways for training and documentation. This technology comprises of a specifically developed and validated force sensor and an IMU, which combined, enables the possibility to provide more exact estimations of the used boxing technique using machine learning (ML) algorithms (anderes boxing paper zitieren). The aim of the study is to include and evaluate different ML algorithms, to establish the best procedure for (kick-) boxing technique recognition (punch, hook, upper cut, backfist, and ridge hand) and target

object recognition (wall, punching bag, and hand pads) in a broad spectrum of fighters with different anthropometrics and experience levels.

METHODS: Two experiments (model development n=13; system evaluation n=8) were conducted to implement models for the striking technique and target object classification. The data samples (n=3453) from the first experiment were used to identify necessary data pre-processing steps, derive a suitable feature extraction method as well as perform model selection by evaluating and optimizing the following classifiers: Decision Tree, Random Forest (RF), Naive Bayes, k-Nearest-Neighbour (kNN), Perceptron, Multi-Layer Perceptron (MLP), Support Vector Machine (SVM) and Logistic Regression. For the evaluation, the three-way holdout method and k-fold cross-validation were used. As performance metrics, the accuracy and f1-score were used. Subsequently, the second experiment was used to evaluate the final models based on new and unseen data from additional participants which were chosen so that they represent a broad sample regarding height, experience level and sex.

RESULTS: The model implementation and selection phase showed that similarly good accuracy results can be achieved with the RF, kNN, MLP and SVM classifiers for the striking technique as well as for the target object classification. The best result for both classification tasks was achieved with the optimized SVM model which was 93.03% for the striking technique and 93.49% for the target object classification based on model development dataset. Regarding the system evaluation dataset (n=1951), the final accuracy for the striking technique classification was 89.55% and 75.97% for the target object classification.

CONCLUSION: The research demonstrated which process steps and components are necessary to be implemented in order to develop a striking technique and target object classification based on data collected using IMU and force measurement sensors of the smart boxing gloves. Furthermore, the implemented models provide a good generalization performance based on the high accuracy results regardless of the broad range of athlete characteristics. This paves the way for further research in this area, as e.g. the automatic assessment of the quality of an executed striking technique which could suppport athletes during their learnining process.

DEEP REINFORCEMENT LEARNING FOR SIMULATING VIRTUAL BOXERS THAT IMITATE THE FIGHTING INTERACTIONS GIVEN IN MOTION CAPTURE DEMONSTRATIONS

YOUNES, M.1, KIJAK, E.2, KULPA, R.3, MALINOWSKI, S.2, MULTON, F.1,3

1 INRIA, IRISA, UNIVERSITY OF RENNES, 2 UNIVERSITY OF RENNES, INRIA, IRISA, 3 UNIVERSITY OF RENNES, INRIA, M2S

INTRODUCTION: VR enables to immerse users in a simulated environment, with simulated opponents in fighting sports, to minimize the impacts and the risk of injuries, while increasing the number of repetitions. However, designing a virtual opponent that behaves and moves as a real opponent would, is still an open problem. Recent approaches include Generative Adversarial Imitation Learning, which enables a virtual character to have realistic behavior learned from large datasets of multiple motion clips [1, 2]. We propose to extend this idea to imitate realistic boxing fights with a little set of examples, i.e. motion capture clips with two opponents. As a result, a real-time controller is designed to compute the relevant joint torques to apply to each physics-based character.

METHODS: We propose to associate an adversarial motion prior (similar to [1]) with a new concept, the adversarial interaction prior. Both priors are based on the same approach, composed of a policy that computes the relevant actions to transit from the current state to the next one. The motion prior uses a single boxer motion clip to compute a reward quantifying to which extent a transition from the current pose to a next one is similar to those viewed in the examples. The interaction prior aims at computing a similar reward but for interaction between two fighters instead of the motion of a single boxer, using a second motion clip with two fighters. A controller (namely a policy) is trained using reinforcement learning to compute the joint torques required to simulate the next pose while maximizing both rewards.

RESULTS: This method has been successfully applied to simulate two virtual boxers fighting each other while imitating the motions of a 6-minute single boxer motion clip, and another 70-second motion clip with two boxers. The results demonstrate the ability of the approach to simulate realistic fighting behaviors.

CONCLUSION: We have proposed a new deep reinforcement learning approach to simulate two-boxers fighting each other while imitating the style of fight given in a 70s example. Future works will tend to control a virtual opponent thanks to this controller, while fighting against a real user, and evaluate the ability to actually reproduce realistic interactions for serious training game in VR.

MACHINE LEARNING FOR AUTOMATED CATCH RECOGNITION IN AMERICAN FOOTBALL TRAINING.

VOLMER, J.C., REITER, B., HOLLAUS, B.

MANAGEMENT CENTER INNSBRUCK

INTRODUCTION: Mastering a sport requires hours of practice. To practice and train efficiently an athlete's abilities have to be monitored precisely. So it is with catching passes in American Football. However, evaluating each pass manually and keeping track of the statistics by hand is a tedious job. State of the art systems for catch recognition, e.g. [1], are accurate

but require IMUs worn by every athlete. To remove this restriction, we propose an audio-visual recording system combined with a machine learning approach to automatically classify catch attempts during training.

METHODS: A camera and a microphone with a directional pattern were mounted on the ball-throwing machine from [2]. After triggering, an audio sequence and an independent video sequence were recorded for each catch attempt. Experiments were conducted both indoor and outdoor with different background types. The recorded dataset, consisting of 2,276 passes, formed the basis for training the neural networks. The dataset was then labelled using two main classes: catch or drop and four sub classes: jump, one-handed, run and stand. In addition, the dataset was augmented using various methods for the video and audio signal and divided in train, validation and test parts.

The machine learning approach was based on a Convolutional Neural Network (CNN) used for feature extraction. To this end, the pre-trained VGG16 [3] network was embedded and combined with a Long Short-Term Memory (LSTM) layer to classify the video data. In addition, classification of the audio data was performed using a one-dimensional CNN.

RESULTS: The network described above was only used to predict the two main classes: catch and drop. Achieved accuracies when using only the audio network range from 76%-81%. Using only the video network 83%-87% accuracy was obtained. When combining both networks, catch attempts were classified with an accuracy of up to 92%.

CONCLUSION: It was shown that the classification of catch attempts using audio and video data is possible. The achieved accuracies are comparable to that of state of the art methods using wearable sensors. Further research should focus on identifying the sub classes and improvement of audio and video only classification.

OP-SH04 Psychology and Motivation

A QUALITATIVE INVESTIGATION OF CHILDRENS PERCEPTIONS OF SCHOOL-BASED PHYSICAL ACTIVITY AND ITS IMPACT ON THEIR COGNITION AND ACADEMIC ACHIEVEMENT.

DIXON, S., HETTINGA, F., TEMPEST, G., MCCULLOGH, N.

NORTHUMBRIA UNIVERSITY

A Qualitative Investigation of Children's Perceptions of School-Based Physical Activity and its Impact on their Cognition and Academic Achievement.

Dixon, S. Hettinga, F. Tempest, G. McCullogh, N.

Northumbria University

Introduction

Physical activity (PA) provides a wealth of benefits to children. Over recent decades, academic research has shown that it might also positively impact their cognition and academic achievement (AA). However, findings are inconsistent, and common conclusions simply state that PA is of no detriment to children's cognition or AA. Further, in this field, qualitative research involving key stakeholders, including children themselves, is sparse. This research aimed to investigate children's perceptions on their school-based PA, and the perceived influence this PA has on their cognition and AA.

Methods

Twenty-one semi-structured focus groups were conducted across two different schools, totalling 77 participants aged between 5 – 12 years old.

Reflexive Thematic Analysis with an inductive and semantic perspective was conducted. Study quality was promoted through several methods, such as peer debriefing, prolonged engagement with schools, and reflexivity.

Results

A notable finding was that most children enjoyed their school-based PA and believed it was beneficial to them. Further, children readily identified aspects they felt either hindered or assisted in the delivery of, or their engagement with, school-based PA, such as lack of time, the impact of schoolwork, and social factors pertaining to peers, teachers and class behaviour. However, whether such aspects were perceived as barriers or facilitators varied between children.

Additionally, children were able to identify the influences they believed school-based PA had on their cognition and AA, discussing aspects such as focus, attention, listening, handwriting and mistakes. However, perceptions again differed between children regarding the extent of the influences and whether these were identified as beneficial or adverse. Additionally, children commonly discussed their requirement for an appropriate 'wind-down' period following their in-school PA, allowing them time to adjust both physically and mentally before continuing with academic content.

Discussion

The inter-relatedness of factors discussed by the children highlights the complexity of the relationships between children's PA and their cognition and AA. The majority of children enjoying PA is a notable finding and remains an under-explored factor in this area. Further, this aligns with Self-Determination Theory, which states that enjoyment leads to prolonged PA participation.

This study provides an important insight into how children perceive their school-based PA, and how they perceive its influence on their cognition and AA. Addressing the barriers and promoting the facilitators identified by children, as well as focusing on their enjoyment, may increase engagement and improve the benefits of school-based PA.

THE EFFECTS OF COACH-CREATED MOTIVATIONAL CLIMATE IN RHYTHMIC GYMNASTICS

LAROËRE, B.M.1, HOROVÁ, E.1, MUDRÁK, J.2, CROSSAN, W.1, TREBICKÝ, V.1

1. FACULTY OF PHYSICAL EDUCATION AND SPORT, CHARLES UNIVERSITY; 2. FACULTY OF ARTS, CHARLES UNIVERSITY

Introduction

Rhythmic gymnastics is an aesthetic sport involving complex and particular training processes with high physical and psychological demands. As in other gymnastics disciplines, the coach plays a crucial role in the development and training of athletes. It is essential that coaches strive to create a positive and supportive motivational climate and nurture an optimal environment for their athletes. This study aimed to investigate the athletes' perception of the coach-created motivational climate in rhythmic gymnastics and its relation to the athletes' motivational and social outcomes.

Methods

Ninety-one rhythmic gymnasts (aged 12 to 18) completed an online survey consisting of several standardised questionnaires, including the Empowering and Disempowering Motivational Climate Questionnaire-Coach, Athlete Engagement Questionnaire, and Youth Sport Environment Questionnaire. The participants were all experienced contestants who competed at the national level (57.1 %) or had international experience at a non-elite level (42.9 %). Using the concept of empowering and disempowering coaching climate, we hypothesised that the empowering climate (represented by greater autonomy, task orientation, social support, and lower ego orientation and controlling coaching) would be positively related to motivational (i.e., athletes' engagement) and social (i.e., team cohesion) outcomes.

Results

The observed patterns of correlations between engagement, team cohesion, and dimensions of motivational climate corroborated our predictions. In regression models, autonomy-supportive climate and task involving motivational climate were the main predictors of athletes' engagement and team cohesion, explaining 43.5 % of the variance in athletes' engagement and 33.1 % in task cohesion. In the k-means cluster analysis, we identified two types of participants, which we labelled as "empowered" and "disempowered". Overall, the disempowering climate was more prevalent, as 57 % of participants belonged to the "disempowered" type. The participants of the "empowered" type reported high levels of task-involving, autonomy-supportive and socially supportive climates and low levels of ego-involving and controlling climates, whereas the "disempowered" gymnasts reported opposite values in all dimensions of motivational climate. Furthermore, the "empowered" gymnasts showed significantly higher engagement and team cohesion.

Discussion

These results suggest that the coach-created empowering motivational climate may be an important predictor of motivational and social outcomes in competitive athletes. Coaches providing higher emphasis on athletes' autonomy and task orientation and lower emphasis on social comparisons and control of athletes might enhance their positive experience of their sport. This environment may be especially important in rhythmic gymnastics, as only a minority of our participants experienced the empowering coach-created motivational climate.

COACH/PEERS/PARENTS NEED SUPPORTIVE QUESTIONNAIRE (CPP-NSQ-FR): PRELIMINARY VALIDATION, AND RELATIONSHIPS WITH ADOLESCENT ATHLETES WELL-BEING.

MAJ, L., TROUILLOUD, D., ISOARD-GAUTHEUR, S.

UNIVERSITY GRENOBLE ALPES

Introduction: In the competitive sports context, coaches, parents, and peers constitute the close social network of adolescent athletes [1]. To date, no measurement scale simultaneously captures adolescent athletes perceptions of the behaviors and attitudes of these three agents. However, this is necessary when it is known that they can foster ill-being in athletes.

Based on self-determination theory [2], the present study aimed to (a) examine the psychometric properties of a french questionnaire (based on the Interpersonal Behavior Questionnaire [3]) adapted to the three actors, designed to measure the need-supportive style of coach, parents, and peers (the CPP-NSQ-Fr), and (b) examine the links between the need supportive style of the three agents on athlete well-being (i.e., vitality, need satisfaction, and burnout).

Method: French athletes in competitive team sports (N = 290; F = 131; Mage = 15.19; SD = 1.56) completed the CPP-NSQ-Fr and questionnaires measuring well-being. Using the R studio software, several evidences of validity were tested: factorial (with CFA), convergent (with factor loadings), discriminant (with inter-factor correlation), internal consistency (with Cronbachs alpha) and criterion validity (correlations with well-being variables).

Results: A hierarchical model with a latent variable for need satisfaction by each actor in the first order, and a latent variable by actor in the second order showed the best fit to the data (χ^2 (546) = 877.02, $p < .001$, CFI = .93, TLI = .92, RMSEA = .05 (90% CI [045-.057]), SRMR = .06), acceptable standardized factor loadings (<.05) and good estimates of internal consistency (α between .76 to .85). The CPP-NSQ-Fr subscales correlated with well-being outcomes in the expected direction. Indeed, CPP-NSQ-Fr subscales were positively correlated with need satisfaction (autonomy, competence, and relatedness) and subjective vitality, and negatively correlated with the dimensions of athlete burnout (reduced accomplishment, negative feelings toward sport, and physical exhaustion).

Discussion: The present study results outlined preliminary validity evidence for the CPP-NSQ-Fr. Further research is needed to confirm these results and to demonstrate the validity of the CPP-NSQ-Fr in different populations (e.g., high performance athletes). In the future, this tool may be used to simultaneously compare athletes perceptions of coach, peers, and parents' need-supportive style. Further studies may also explore the potential interactions between athletes perceptions of their social environment and links with well-being.

EXPLORING THE ROLE OF INTENSITY PREFERENCE AGREEMENT ON BASIC PSYCHOLOGICAL NEEDS, ENJOYMENT, INTENTION TO CONTINUE EXERCISING, AND EXERCISE FREQUENCY: A MODERATED MEDIATION ANALYSIS

TEIXEIRA, D.S., ANDRADE, A.J., FARIA, J., MARQUES, P., BASTOS, V., RODRIGUES, F., SOUSA, A.M., PEREIRA, H.V.

ULHT - UNIVERSIDADE LUSÓFONA DE HUMANIDADES E TECNOLOGIAS

Introduction

Several theoretical frameworks have been used to understand and promote exercise adherence. Basic psychological needs, grounded on self-determination theory, have received large attention for this purpose. More recently, the hedonic theory and the assumptions related to the exercise characteristics that can bolster positive affective responses have been revitalized. One of those characteristics pertains to the way exercise intensity is being experienced by the individual. Given the need to further explore theoretically integrated models and their interaction mechanisms, this study aimed to explore the associations between the agreement of current exercise intensity and the one individually preferred (as a trait characteristic), basic psychological needs satisfaction/frustration, enjoyment, the intention to continue exercise, and exercise frequency. Additionally, an exploration of the direct and indirect effects, while also testing for sex as a moderator, was also intended.

Methods

A sample of 369 health club exercisers (Mage = 43.6, SD = 12.96; 214 females) enrolled in 26 health clubs representing all districts in Portugal participated in this study voluntarily. Data received in a first approach descriptive and correlational analyses. Next, a moderated mediation was performed using model 15 (PROCESS v.4.2 macro for SPSS v.26.0). This model assumes an independent variable (preference agreement), parallel mediators (six; autonomy, competence, and relatedness satisfaction; autonomy, competence, and relatedness frustration), a dependent variable (separately: enjoyment, intention, frequency), and a moderator (sex; tested in the independent > dependent variable path, and mediators > dependent variable paths).

Results

Agreement in preference for exercise intensity was positively associated with enjoyment, intention, and all needs satisfaction, and negatively associated with all needs frustration. In the moderated mediation analysis, the same pattern of results emerged in the direct effects. Indirect effects were significant for autonomy in most of the models. Regarding sex as a moderator, the most relevant interactions were detected with preference and with autonomy satisfaction in the enjoyment and intention models.

Discussion

Findings suggest that promoting an individually adjusted training intensity may foster basic psychological needs satisfaction. It appears to be present an independent (of needs) but positive association with exercise enjoyment and intention to continue exercising, two well-known predictors of exercise behavior. Also, sex appears to differentiate how preference agreement and some psychological needs relate to these outcomes. In general, partial mediation results were detected, highlighting the need to consider individual characteristics in exercise prescription/supervision when aiming to promote the conditions for the development of self-determined and sustainable behavior.

THE 'WHAT' OF ATHLETES' GOAL PURSUIT: RELATIONSHIPS TO THE PERCEIVED MOTIVATIONAL CLIMATE, GOAL-RELATED PROCESSES, AND WELL-BEING

MARTÍNEZ-GONZÁLEZ, N., ATIENZA, F.L., DUDA, J.L., BALAGUER, I.

UNIVERSITY OF VALENCIA

Introduction

Goal Contents Theory (GCT) [1] postulates that the goals people pursue not only direct their perceptions of and behaviours relevant to goal pursuit, but also hold implications for their well-being. According to GCT, intrinsic goals (e.g., mastery, personal growth, self-expression) should link to more adaptive goal processes and optimal functioning while extrinsic goals (e.g., social recognition, popularity, superiority) are expected to correspond to maladaptive goal processes and compromised well-being. Past research [2] has found the perceived motivational climate on a team to predict the 'why' (motives) of goal pursuit but little is known whether this social environmental factor relates to 'what' (goal content) is being pursued in sport.

Extending past sport work grounded in GCT, this study examined whether athletes' self-generated goals were differentially aligned with empowering and disempowering coach climates, goal-related processes (self-efficacy for goal attainment, perceived goal difficulty, goal-directed effort), and well-being (vitality, burnout).

Methods

414 University team sport athletes (M = 20.61; SD = 2.58 years of age; male (n=206), female (n=208)) provided their goal for the season via an idiographic methodology and responded to validated scales tapping the targeted goal-related processes, perceptions of the motivational climate and positive and negative indicators of well-being. Three expert judges deductively coded the goal content.

Results

Fleiss' Kappa revealed substantial agreement amongst coders; 60.8% of the goal content was classified as intrinsic, 31.1% extrinsic and 8% ambiguous. Women reported more intrinsic goals compared to men. MANCOVA (with gender as a covariate) revealed that athletes who pursued extrinsic goals reported significantly lower self-efficacy ($\eta 2$ =.02), greater goal difficulty ($\eta 2$=.10) and perceived the motivational climate to be more disempowering ($\eta 2$ =.03) than athletes with intrinsic goals. No differences in well-being indicators emerged.

Discussion

Findings were largely congruent with GCT and indicate that: (a) features of the motivational climate hold implications for the type of goals athletes pursue, and (b) the quality of athletes' goal-related processes vary as a function of whether they are pursuing intrinsic or extrinsic goals. Future work may address whether an interplay between goal content and athlete well-being emerges when examined as the season progresses.

OP-SH25 Qualitative and quantitative methods

ASSESSMENT OF VARIABILITY IN PREFERENCE AND TOLERANCE TO EFFORT INTENSITY AND AFFECTIVE RESPONSES

TAKITO, M.Y., TAVARES, M.A.D., PEREIRA, R.M., SILVEIRA, R.

SCHOOL OF PHYSICAL EDUCATION AND SPORT OF UNIVERSITY OF SAO PAULO

Introduction

Understanding psychological variables along with the individual characteristics and motivations of subjects are interesting tools to associate with quality and adherence to physical activity. Recent studies have focused on hedonist theories to relate physical activity enjoyment and the biopsychosocial factors involved in the prescription of physical training. This study aimed to assess the effects of exercise intensity preference and tolerance over time, their link to affective responses, and subjective perception of effort in a 3-month self-paced training program.

Methods

Twenty-one adults of both sexes were randomly allocated to two groups based on their baseline scores on the Exercise Intensity Preference and Tolerance Questionnaire (Smirnaul et al. 2015). A personalized follow-up program was applied remotely for 3 months, with three weekly training sessions lasting 60 minutes, two supervised by a professional and one unsupervised. Participants reported their preferences and tolerances for exercise intensity, perceived exertion, and enjoyment each month. The effects of preference, tolerance, perceived exertion, and enjoyment (Alves et al. 2019) over time and between groups were observed using Anova two-way with a significance level of $p < 0.05$ and Power 1-ß >0.8.

Results

There was no significant effect on exercise intensity preference over time. The group with lower scores showed approximately 27-31% less tolerance over time with differences at the start and at the 3rd month ($p<0.05$). The group with lower scores showed increased tolerance until the 2nd month with a decline in the 3rd month, inversely proportional to the group with higher scores. Enjoyment presented a significant difference between groups at the start ($p<0.05$), with the

group with lower scores having less enjoyment, without differences over time. The perceived effort was lower in asynchronous training than in synchronous training sessions, with significant effects of time on perceived effort in both types of sessions (p <0,001). In the group with the lowest preference and tolerance score, it was observed that despite an increase in perceived effort, tolerance decreased.

Discussion

The findings suggest that individuals who initially had lower exercise preference and tolerance showed a significant improvement in both tolerance and enjoyment in the first two months of the study. However, there was no significant change in exercise intensity preference over the three-month period. Its important to note that these individuals did not show an increase in tolerance similar to those with higher scores, and also they reported a higher subjective perception of effort.

COGNITIVE ABILITIES EVALUATION OF EXPERT ATHLETES : SCIENTIFIC VALIDATION OF TESTS BATTERY

FERNANDEZ, L., RELOT, T., DEPIEDS, L., LE CHANONY, E., GUIDI, O.

HUMAN MOVEMENT INSTITUTE, CREPS PACA, MAISON RÉGIONALE DE LA PERFORMANCE, RÉSEAU GRAND INSEP

To be an expert in sport result of fine adaptations on the physical, technical, psychological and cognitive levels. For a long time, Sports sciences have examined the methods of physiological and technical development and they thus become essential in the preparation of athletes. While tests to measure the physiological and physical abilities of an athlete (e.g. Vameval test, force test) are widely standardized and referenced in the literature, the investigation of cognitive abilities still remains unclear and equivocal.

The present study was based on the postulates of the cognitive skills approach, which studies the differences between athletes by testing their basic cognitive abilities through standardized laboratory tests, dissociated from the sport context. Using a battery of cognitive tests to investigate different cognitive skills, the objective of the current study was to determine how expertise in a sport shaped the athletes cognitive identity card. The hypothesis that there is a specific development of certain skills according to the sport practiced was tested (as well as the link between this development and the level of expertise of the athletes).

A battery of cognitive tests was proposed to measure (i) executive functions (motor inhibition (Go/No Go task), cognitive flexibility (switching task), working memory (N back Task)), (ii) selective attention (Flanker task) and (iii) information processing (perceptual visual task).

98 athletes of national level (61 males & 27 females, average age : 16.3 ±1.5) classified according to 3 categories of sport were involved in the experimental protocol (N = 40 for interception sports, N = 23 for static sports and N = 35 for strategic sports).

The results confirmed the law of information processing. Indeed, complexity of the processing process manipulated through the experimental conditions for each test resulted in increased processing time and lower success rates regardless of the sport. This main result allow us to validate our cognitive test battery. Secondly, differences obtained in dominant cognitive functions across sport types showed that athletes practicing interception and strategic sports performed better on the selective attention task, while athlete in interception sports showed better performance on motor inhibition and working memory test. Thus, the results of this study validate an operational test battery for the sports domain that reliably measures executive functions.

The prospects for the integration of this test protocol to the already well known physiological and physical test battery is of particular interest and really promising to complete the identity card of the athlete at different levels. Furthermore, later on, the choices and orientations of cognitive training protocols will be all the more relevant as they will be based on reliable and complete scientific data.

Waseda University

Introduction

The Sport Imagery Intervention Questionnaire (SIIQ) was developed to assess athletes use of imagery intervention. SIIQ was developed based on PETTLEP model of imagery (Holmes & Collins, 2001). This model provides a framework for the effective execution of seven imagery interventions (i.e., Physical, environment, task, timing, learning, emotion, and perspective). Because imagery is related to performance, it is important to understand whether such imagery interventions can be evaluated.

Methods

In this three-part study, the psychometric properties of the SIIQ were addressed. After items were developed based on constitutive definitions representing each of the seven elements of the PEPPLEP model to measure athletes use of imagery intervention, SIIQ's factor structure was verified using exploratory factor analysis (EFA) and confirmatory factor analysis (CFA). Multivariate analysis of variance (MANOVA) was used to evaluate the group differences in SIIQ (such as gender and subjective performance level). Finally, correlation and regression with imagery ability were investigated.

Results

In study 1 (N = 366) EFA revealed a 10-factor model assessing imagery intervention of physical, environment, task, timing-real, timing-slow, timing-fast, learning, emotion, perspective-third-person, perspective-first-person and these were confirmed through the CFA conducted in study 2 (N = 442) and study 3 (N = 378).

Result demonstrated good fit with the data of the 10-factor model. Additional validation of the SIIQ demonstrated good temporal reliability and concurrent validity. SIIQ scores distinguish between athletes with varying subjective performance levels. However, there was no significant gender difference in SIIQ mean scores. Several SIIQ subscales positively predicted imagery ability.

Discussion

The SIIQ provides a comprehensive assessment of athletes use of imagery intervention through ten subscales.

The results highlight the importance of separately evaluating imagery interventions for timing as timing-real, timing-slow, timing-fast, and perspective as perspective-third-person, perspective-first-person. These were confirmed through series of CFAs. A 7-factor model in which timing-real, timing-slow, and timing-fast items were forced onto a timing subscale and perspective-third-person and perspective-first-person items were forced onto a perspective subscale revealed a poorer fit than 10-factor model.

SIIQ discriminated among athletes of different subjective performance levels. Athletes with a higher subjective performance level significantly used imagery intervention more in their sport compared with those with a lower level. SIIQ subscales predicted imagery ability positively, which suggests how the SIIQ can be practically applied in the sporting field. Overall, SIIQ has excellent psychometric properties.

APPLYING THINK ALOUD TO APPLIED SPORT PSYCHOLOGY PRACTICE

WHITEHEAD, A., MCEWAN, H., TOD, D., VAUGHAN, S., SWETTENHAM, L., BIRCH, P., JACKMAN, P.

LIVERPOOL JOHN MOORES UNIVERSITY

Introduction

The Think aloud (TA) method involves an athlete or participant verbalizing his or her thoughts whilst performing a task and has been used in sport research to generate understanding of athlete cognition (e.g., Whitehead et al., 2016;2018). This research often suggests the benefits of TA as a useful tool for applied sport psychologists (ASP) in service-delivery with clients. However, no study has yet explore how practitioners could use TA within their practice. To address this gap, we explored trainee and registered ASP's use of TA in practice, when working with clients.

Methods

A workshop was delivered to ASP's (n = 25, registered and trainees) on how TA could be used with clients. At approximately 4 and 12 months' post workshop, 11 participants (5 females and 6 males) with 1-15 years of professional experience were interviewed to share the story of their use of TA in their practice. Data analysis began with an examination of the narrative structure of the practitioners' stories, followed by an investigation of the narrative themes related to factors influencing its effectiveness. A composite vignette was developed to fuse the account of multiple participants to represent our findings.

Results

A story of Steve the ASP and Barney the darts player provides an account of how TA can be used within sport psychology practice. We found that TA influenced client self-awareness, particularly in the needs analysis and intervention phases. Practitioner confidence in applying TA was shaped by the practitioner-client relationship.

Discussion

This study extends literature on TA by demonstrating how ASP's can use the method as a collaborative applied practice tool at multiple stages of the consultancy process. We encourage ASP's to use the method in creative and meaningful ways to support their clients.

PSYCHOMETRIC VALIDATION OF THE FRENCH VERSION OF THE COACH-ATHLETE RELATIONSHIP QUESTIONNAIRE

ROUX, V., TROUILLOUD, D.

LABORATOIRE SENS

Introduction.

For the past twenty years, the Coach-Athlete Relationship Questionnaire (CART-Q; Jowett & Ntoumanis, 2004) has been considered as an effective measurement tool to explore the coach-athlete relationship (CAR) quality (in terms of closeness, commitment, complementarity, and co-orientation). However, although few studies used a French translation of the CART-Q, these did not focus on evaluating the psychometric properties of this scale. The two present studies aim to contribute to the psychometric validation (i.e., factor structure, discriminant, convergent, criterion validity, and temporal invariance) of a French athlete version of the CART-Q among two different samples.

Method.

In the first study, 442 athletes (Mage = 21.66, SD = 4.82; 34.2% of women) from both individual and team sports competing at different levels completed a French translation of the 11-item CART-Q. For study two, 282 young handball players (Mage = 15.39, SD = 1.01; 41.6% of women) involved in intensive training centers completed at two measurement times (early and mid of the season) a revised 12-item French version of the CART-Q. Confirmatory factor analysis and structural equation modelling were conducted to explore the psychometric properties of the CART-Q.

Results.

Results of the first study indicate a satisfactory fit of the second-order model (χ2/df = 4.97; CFI = .90; SRMR = .05), a satisfying convergent validity (factor loadings above 0.63), and a good criterion validity with athletes' perceptions of self-competence (b = .30, p <.001). In the second study, results also reveal a satisfactory fit of the second-order model (χ2/df = 3.96; CFI = .90; SRMR = .07), a satisfying convergent validity (factor loadings above 0.55), and a good criterion validity (b = .34, p <.001). In addition, results provide evidence for the temporal invariance (scalar invariance: χ2 >.05; delta CFI <.01) of the CART-Q over time.

Discussion.

These two studies provide evidence for the psychometric validity of the 12-item French revised version of the CART-Q. In addition, the second study is the first – to our knowledge – to highlight the temporal invariance of the CART-Q. This result suggests that despite the dynamic nature of the CAR (Roux et al., 2022), the factorial structure of the CART-Q remains stable over time. Thus this 12-item French version of the CART-Q can be considered as adapted to measure the CAR quality among French-speaking athletes.

THE INFLUENCE OF RESISTANCE TRAINING AND PROBIOTICS SUPPLEMENT ON INSULIN SENSITIVITY AND COGNITIVE FUNCTION IN ELDERLY

HSIAO, H.J.1, WU, C.L.1, WU, S.L.2, CHANG, C.K.3, HE, H.H.1, HSIEH, C.C.1

NATIONAL CHUNG HSING UNIVERSITY1, CHUANGHUA CHRISTIAN HOSPITAL2, NATIONAL TAIWAN UNIVERSITY OF SPORT3,

INTRODUCTION: Aging associated with sarcopenia, gut microbiota dysbiosis, cognitive function decline, and insulin resistance. Maintaining muscle mass and gut microbiota abundance may be beneficial for insulin sensitivity and cognitive function during aging process. However, limited studies examined the the impact of exercise and probiotics in the elderly. The current study was to investigate the effect of resistance training and probiotic supplementation on gut microbiota, insulin sensitivity, and cognitive function in healthy elderly.

METHODS: A total of 36 volunteers over the age of 65 were recruited for this study(71.3±6.1yrs). The participants were randomly assigned into three groups : resistance training + placebo (R), resistance training + probiotics (RP), and probiotics supplement (P). The R & RP groups were instructed to complete a 6-week resistance training program. The RP and P groups were asked to consume probiotic for 6 weeks. Participants were asked to give their fasting blood samples, feces samples and to complete stroop test, fitness tests, body composition before and after the 6-week intervention. Plasma samples were analyzed plasma biochemistry markers and cytokines. Feces samples were analyzed gut microbiota.

RESULTS: The RP group significantly reduced fasting plasma glucose (p<.05), and the RP & R group significantly increased GLP-1 (p<.05) after the intervention. The insulin sensitivity assessed by HOMA-IR, QUIKI index and McAuley index were no

differences before and after intervention in each group (p>.05). The abundances of Fusobacteria and the Simpson index were significantly reduced (p<.05) in R group. The Firmicutes/Bacteroidetes (F/B) ratio were significantly negatively correlated to QUICKI index and TC/HDL-C (p<.05). There were no significant differences in plasma lipids profiles before and after intervention in each group (p>.05). Among the change of plasma cytokines concentrations, the R group was found a significant increase in IL-6 (p<.05) after intervention. Plasma brain-derived neurotrophic factor (BDNF) concentration was significantly increased following the R group and the RP group compared with the P group (p<0.05). In the stroop test, the R group and the RP group significantly reduced the time required to complete the word and color tests (p<.05), and the R group also significantly reduced the time required to complete the incongruent test (p<.05).

CONCLUSION: The current study suggested that the resistance training and probiotic supplement improved cognitive function and gut microbiota abundance in older adults. The changes in the proportion of dominant gut microbial species ratio may be closely related to the risk of metabolic disorders in the elderly. Regular resistance exercise program in combination with probiotics supplement is likely to have positive health effects in the elderly.

EFFECTS OF RESISTANCE EXERCISE WITH INSTABILITY ON PHYSICAL AND COGNITIVE FUNCTIONING OF MIDDLE-AGED AND OLDER ADULTS: SYSTEMATIC REVIEW WITH PRELIMINARY META-ANALYSIS

CAVALCANTE, B.R., FALCK, R.S., DA SILVA, D.T., CAMPOS, I.R.A., SILVA, M.S., TOMAZ, M.L.L., SILVA, Y.A., SOUZA, M.S., DE ARAÚJO, R.C.

UNIVERSIDADE FEDERAL DO VALE DO SÃO FRANCISCO

INTRODUCTION: Resistance Exercise (RE) is an effective preventive and treatment strategy to combat many geriatric syndromes including sarcopenia, frailty, and cognitive impairment. Recent evidence suggests that RE with instability (REI) (e.g., weight-bearing, machine-based or free-weight exercise using unstable surfaces/devices: foam pads, Swiss ball, BOSU®) is a promising intervention to maximize the benefits of RE on health outcomes in older adults. With this in mind, we performed a systematic review with preliminary meta-analysis to examine the impact of REI on physical and cognitive functioning, falls risk and quality of life.

METHODS: We searched electronic databases (PubMed, APA/PsycInfo and PEDro) from inception to January 2023 to extract data of eligible hits who examined the chronic effects (>4 weeks) of REI, compared with a control group (lifestyle maintenance, wait list, usual care, health education or active control), on the physical and cognitive functioning of older adults living independently in the community. Included articles were peer-reviewed, randomised controlled trials and without establish language restrictions. Risk of bias and quality of reporting were assessed (PEDro Scale and CONSORT checklist, respectively). In our preliminary meta-analysis, we performed random-effects models using robust variance estimation to examine the effects of REI on physical function, cognitive function, falls risk, and quality of life.

RESULTS: Eighteen studies with participants from Brazil, Spain, German, and South Korea (Total n=525, aged 50+ year, %woman varying from 35-100%) were included in the qualitative review and 11 studies in the meta-analysis. Eleven studies provided 103 effect sizes examining the effect of REI on physical function, with Hedge's g ranged between -1.71 and 2.52. The summary effect was g=0.61 (95%CI: [0.35,0.86]; p<0.001), which is representative of a medium-to-large effect. More than two-thirds of the variance was estimated to be true effect size heterogeneity (I2=70.33%, tau2=0.27). Five studies provided 26 effect sizes investigating the effect of REI on cognitive function, with Hedge's g ranging between -0.27 and 1.90. The summary effect was g=0.67 (95%CI: [0.08,1.27]; p=0.035) which is indicative of a medium effect. Nearly half of the variance was estimated to be true effect size heterogeneity (I2=61.75%, tau2=0.21). The effects of REI on falls risk and quality of life the summary effect did not reach statistical significance (p's>0.05).

CONCLUSION: In summary, our findings suggest that REI is a promising strategy to promote physical and cognitive health of middle-aged and older adults. Further high-quality research is needed to strengthen the evidence in this field.

WHAT IS THE LONG-TERM EFFECTS OF RESISTANCE TRAINING WITH INSTABILITY IN COGNITIVE FUNCTION OF OLDER ADULTS WITH PROBABLE MILD COGNITIVE IMPAIRMENT? A RANDOMIZED CLINICAL TRIAL

SILVA, D.T., ARAÚJO, R.C., RODRIGUES, C.F., PEREIRA, T.N., OLIVEIRA, J.S., GUIMARÃES, I.K., SILVA, K.M., PINHO, A.M., CAMPOS, I.R., SILVA, M.S., TOMAZ, M.L., CAVALCANTE, B.R., SOUZA, M.F.

UNIVERSIDADE FEDERAL DO VALE DO SÃO FRANCISCO

INTRODUCTION: An impaired cognitive function is a hallmark of mild cognitive impairment (MCI), an established risk factor for dementia. Systematic reviews with meta-analysis showed that exercise training, including resistance training is effective to promote cognitive health in cognitively impaired older adults. Some studies proposed that exercise paradigms that embody high motor complexity is promising to boost cognition. Resistance training with instability (RTI) featured by combining strength exercises with dynamic balance conditions– is a such strategy. Clinical trials with RTI in the short term show controversial results in cognitive function. Long-term effects of RTI were not established. Herein, we examined the effects of 24-weeks of RTI on cognitive function of older adults with probable MCI.

METHODS: This is a 2-group parallel, assessor blinded, single-site, randomized clinical trial (RBR-9bv3dc9). Non-disabled, sedentary, older adults with probable MCI, aged 65 years and older were included. They were randomized into twice-

weekly RTI program or a sham-training, attention-matched control group (CG). The RTI protocol involved 3-sets of 10-15 maximum repetitions, seven whole-body exercises, simultaneously performed with instability devices (e.g., foam-pad, Bosu®, Swiss ball), that were progressively implemented. The CG included low intensity/no progression of strength, balance, stretching, and relaxation classes. Measurement occurred at baseline, 12-, and 24-weeks. Global and domain-specific (executive functioning [EF] and memory) cognitive function were assessed using the Montreal Cognitive Assessment (MoCA), Stroop Test, Trails part A and B, Digit Span (DS) Forward and Backward, Digit Symbol, Verbal Fluency (VF), and Wechsler Memory Scale. Treatment effects followed the intention-to-treat and were determined through ANCOVA controlling for age and baseline levels.

RESULTS: Ninety-one older adults with probable MCI (MoCA=20.0, SD=4.5) were included in the study (RTI=45; CG=46), most were female (78%), mean age of 71 years (SD=4.8) with an average of 12 years of education. In 12-weeks, participants of RTI group had greater performance in delayed memory (Mean difference [MD]=3.8 recalls, 95%CI=0.2; 7.4) compared to CG. At the same time-point, we observed a significant deterioration in executive functioning (Trails B: MD=43.8 sec, 95%CI=13.0; 74.7; Trials B–A: MD=45.4 sec, 95%CI 13.0; 77.8). At completion of 24-weeks, the RTI had greater improvement in language (VF: MD=1.6 words, 95%CI=0.1; 3.1), attention and working memory (DS Forward: MD=1.0-point, 95%CI=0.3; 1.8; DS Forward–Backward: MD=0.8-point, 95%CI=0.3; 1.7) compared to CG.

CONCLUSION: Our findings indicated that long-term RTI is effective to promote executive functioning of older adults with probable MCI. Therefore, RTI a promising multicomponent intervention to combat cognitive decline during aging.

Key words: Aging, cognitive impairment, balance, resistance training, unstable devices.

EFFECTS OF "ECCENTRIC WALKING" ON PHYSICAL FUNCTION AND HEALTH PARAMETERS IN MIDDLE-AGED AND OLD REGULAR WALKERS

KATSURA, Y.1, TAKEDA, N.1, INAMI, T.2, YAMAGUCHI, S.2, TAKAHASHI, S.3, NAKAMURA, M.4, NOSAKA, K.5

1KOGAKUIN UNIV. , 2KEIO UNIV. , 3DAITO BUNKA UNIV. , 4 NISHIKYUSHU UNIV. , 5EDITH COWAN UNIV.

INTRODUCTION: Walking does not increase muscle strength as resistance exercise does [1]. Our previous study [2] showed that eccentric exercises using body weight load such as sitting to a chair slowly increased leg extensor muscle strength and size, balance and mobility. Therefore, it is possible that adding eccentric exercise components in daily walking such as descending stairs or slopes and lunges (i.e., eccentric walking) improves muscle function. We investigated the effects of eccentric walking on physical function, blood and cognitive function tests in middle-aged and older adults who had been walking regularly for ≧3 years.

METHODS: Eleven adults (69.3±10.4 y) who had more than 5000 steps in exercise walking at least 5 days a week participated in this study. During the 12-week study period, participants walked as usual for the first 4 weeks and added eccentric walking into their walking routine by including lunges, and descending stair or slope walking for the next 8 weeks. The number of eccentric walking steps was gradually increased from 100 to 1000 steps over 8 weeks. Outcome measures included maximal voluntary isometric contraction torque of the knee extensors (MVC), 30-seconds chair stand (CS), 2-minutes step, balance ability assessed by center of pressure movement distance and area with eyes open (BAL-dis-EO, BAL-area-EO) and close (BAL-dis-EC, BAL-area-EC), sit and reach, a digit symbol substitution test (DSST) for cognitive function. These were assessed before, after the control period (week 4), after 4 weeks (week 8) and 8 weeks of eccentric walking intervention (week 12). Cholesterol, triglycerides and glucose in the fasting blood were measured before, week 4 and 12. Changes in the variables over time were analysed by one-way ANOVA.

RESULTS: The average steps per day were 10535±3516 in the first 4 weeks, and 10118 ± 3199 in the eccentric walking period without a significant difference. No significant changes in any of the measures were evident in the first 4 weeks. Significant ($P < 0.05$) improvements were observed in MVC (31.0±8.1→36.3±12.4 kg), CS (19.0±2.7→23.4±4.9 times), BAL-dis-EC (224.5±61.4→174.8±55.4 mm), and DSST (38.5±4.9→44.9±7.1 points) from week 4 to 12. Significant ($P < 0.05$) improvements were also observed for BAL-dis-EO (176.6±37.6→149.6±26.1 mm) and BAL-area-EO (117.6±40.1→84.3±30.9 mm2) from week 8 to 12. No significant changes in any of the blood tests were evident.

CONCLUSION: These results suggest that eccentric walking improved some physical and cognitive function that cannot be achieved by normal walking for the middle-aged and older individuals who had been walking regularly. It is possible that the intervention duration was too short to see changes in the blood tests. The eccentric walking should be implemented for a longer period to examine its effects on health and fitness using a larger number of individuals.

FOUR YEARS OF PHYSICAL EXERCISE IMPROVED COGNITION: EPD (EXERCISE FOR PREVENTION OF DEMENTIA) RANDOMIZED CONTROLLED TRIAL

CENTORBI, M., IULIANO, E., BUONSENSO, A., DI MARTINO, G., DELLA VALLE, C., FIORILLI, G., DI CAGNO, A., CALCAGNO, G., DI COSTANZO, A.

UNIVERSITÀ DEGLI STUDI DEL MOLISE

INTRODUCTION: Practice of regular physical activity (PA) positively influences health, also regardless the dementia risk, with minimal side effects.

Aim of this Randomized Controlled Trial (RCT) was to verify whether a 48-month program of supervised and standardized PA can influence the cognitive decline among older adults at risk of dementia, with a differentiation among groups within healthy people, people with Subjective Memory Complaints (SMC) and Mild Cognitive Impairment (MCI) (Iuliano, 2019).

METHODS: 674 participants, divided in an experimental group (EG) who took part in three time per week physical activity, and a sedentary control groups (CG), underwent 12, 24, 36 and 48 months assessment sessions based on the neurocognitive battery that included Mini-Mental State Examination (MMSE), Frontal Assessment Battery (FAB), Rey's Auditory Verbal Learning Test, Prose Memory Test, Attentive Matrices Test, Raven's Progressive Matrices, Stroop Color Word Interference Test, Trail Making Test (TMT), and Copying of Drawings, to evaluate differences among time-points and groups.

RESULTS: Concerning the MMSE score, GLMM analysis showed significant differences between EG and CG ($F1,2364 = 4.215$; $p = 0.040$), and over time ($F4,2364 = 13.356$; $p < 0.001$). FAB scores showed significant differences between EG and CG ($F1,2364 = 4.113$; $p = 0.043$), and over time ($F4,2364 = 5.237$; $p < 0.001$). In the two memory participants reached significant better performance over time ($F4,2364 = 8.820$; $p < 0.001$) and than CG ($F1,2364 = 17.281$; $p < 0.001$), even after 24 months. The Attentive Matrices' Test, showed significant differences between EG and CG ($F1,2364 = 15.873$; $p < 0.001$), and over time for EG ($F4,2364 = 3.354$; $p = 0.010$) after 12 months.

CONCLUSION: At least 48 months of regular PA are needed to reach significant differences between active and sedentary subjects in the global cognitive level assessment, while the single cognitive domains, such as memory and attention, were influenced in a relative shorter time (12-24 months). The SMC showed a significant improvement overtime only in the two memory tests. The MCI participants showed no change in tests' results over the 48 months, except in all the memory tests and have the most unstable values.

These results suggested that the adherence to long term PA protocols ensures a conservative effect against the natural cognitive decline due to aging (Kumar, 2022). An active lifestyle, taken up in a healthy state, without the presence of full-blown pathologies, showed its effectiveness in terms of delay the cognitive decline.

COACHES' SELF-EFFICACY TO INCLUDE ATHLETES WITH DISABILITIES IN BADMINTON: THE ROLE OF PSYCHOLOGICAL NEEDS' SATISFACTION

OCETE, C., GUTIÉRREZ, A., DELGADO, M., FRANCO, E.

UNIVERSIDAD PONTIFICIA COMILLAS1; FEDERACIÓN ESPAÑOLA DE BÁDMINTON 2

Introduction

Physical activity levels among people with disabilities are inadequate to reach recommended levels, lagging behind the levels achieved by typically developing people (King et al., 2013). How competent coaches feel to include athletes with disabilities in their daily practice has been identified as an important barrier to the development of inclusive sport contexts (Feltz & Lirgg, 2001). Literature suggests that coaches' motivational patterns can influence their professional beliefs and behaviours. This study aims to explore whether coaches' psychological needs' satisfaction might predict their self-efficacy to include athletes with disabilities in their practice sessions.

Methods

The sample consisted of 102 Spanish badminton coaches (72 male and 30 female) aging between 24 and 66 years old ($M = 40.72$ and $SD = 10.55$). Participants completed a validated questionnaire to measure their psychological needs' satisfaction as well as their self-efficacy to include athletes with disabilities in their practice sessions. A stepwise regression was used.

Results

The analysis revealed that only competence satisfaction acted as a predictor for self-efficacy to include students with disabilities in their lessons ($t = 2.63$, $p. < .05$). Neither autonomy ($t = -.04$, $p. > .05$) or relatedness satisfaction ($t = .93$, $p. > .05$) emerged as significant predictors for self-efficacy to include students with disabilities.

Discussion

The findings of the present study highlights that competence satisfaction might be a relevant predictor of badminton coaches' self-efficacy to include athletes with disabilities. This fact is not surprising given the similarities between both constructs, and aspects such as their previous training experiences could be affecting both constructs. Interestingly, neither autonomy nor relatedness satisfaction seemed to be related to teachers' self-efficacy. While these psychological needs have been found to be linked with outcomes such as coaches' well-being or the creation of autonomy-supportive

settings, they might be playing a less relevant role when it comes to exploring teachers' ability to foster inclusiveness in contexts with athletes with disabilities. This study sheds some light in the understanding of constructs which might be provoking the difficulty to foster inclusiveness in sport.

EXPLORATION OF BARRIERS AND FACILITATORS TO PHYSICAL ACTIVITY IN ADULTS WITH SCHIZOPHRENIA INVOLVED IN A LONG-TERM PSYCHOSOCIAL REHABILITATION PROGRAMME

AUGUSTIN, A., MULIN, E., CHALABAEV, A., GRUET, M.

UNIVERSITÉ DE TOULON, CLINIQUE INICEA-LE-VAL-DU-FENOUILLET

Introduction

Regular physical activity (PA) has positive effects on cardiometabolic risk factors, cognition and quality of life in people with schizophrenia (pwSCZ) (Girdler et al., 2019). However, pwSCZ exhibit high levels of physical inactivity and poor adherence to exercise programs, making the identification of factors underlying positive PA behaviours important (Bernard et al., 2013). Barriers to and facilitators of PA have been mainly investigated in small samples of individuals or in pwSCZ hospitalised for an acute episode, sometimes also including other severe mental illnesses (Firth et al., 2016; Rastad et al., 2014). The results of these studies may not apply to clinically stable pwSCZ involved in a long-term psychosocial rehabilitation programme who may experience specific levers and barriers to PA.

Methods

Forty-one clinically stable pwSCZ (age = 32 ± 9 years; n = 12 women) residing in a French psychosocial rehabilitation centre underwent semi-structured face-to-face interviews, to assess their perceptions of barriers and facilitators to PA practice which were analysed using a qualitative content analysis. Poverty of speech being one symptom in this population, pwSCZ were also asked to rate items previously identified as barriers and facilitators to PA in pwSCZ (Bernard et al., 2013) on a 5-point Likert scale.

Preliminary results

Twenty-six interviews were analysed so far (mean duration = 30 ± 7 min). Qualitative content analysis revealed that weight loss, pleasure for PA and practicing with a group were the main facilitators of PA. The main barriers were fatigue, lack of motivation and addictive substance consumption. The highest-ranking facilitators from quantitative analysis were improvement of general health, improvement of well-being and weight loss. The barriers to PA with the highest scores were fatigue, high level of stress or depression, and poor general health.

Conclusion

The present findings should help structures welcoming pwSCZ such as rehabilitation clinics to promote PA practice. Helping pwSCZ find a PA they enjoy, organising collective programs focusing on weight loss and providing therapeutic care to help manage identified barriers such as fatigue, amotivation and substance consumption might help promote positive PA behaviours among pwSCZ.

Introduction

Stereotypes are captured by two fundamental dimensions : warmth and competence (1). People with physical disability (PWPD) are mostly perceived as warm but not competent. This perceived incompetence is the cause of the discrimination they may experience (2).

Studies on the exerciser stereotype applied to PWPD have shown that practicing a physical activity could be a promising strategy to increase perceived competence (3). In this study, we aimed to demonstrate the role of the level of sport participation (recreational vs elite vs no sport information) on the stereotype content associated with PWPD.

Furthermore, research on social perception has suggested that competence and warmth dimension can be, each one, divided into different facets (4). We therefore aimed to distinguish the facets in the stereotype content associated to PWPD in order to have a more precise picture of the stereotype and contribute to a better understanding of the exerciser stereotype phenomenon.

Method

593 participants were randomly assigned in three experimental target conditions (elite athlete, recreational athlete, or control with no athlete status) to read the description of a physical disabled target i n which information about the athlete status was manipulated. After reading the description, participants rated the level of competence (including capability, assertiveness and courage facets) and warmth (including morality and sociability facets) that they perceived towards the target. Participants responded on a 7-point scale (from 1 "strongly disagree" to 7 "strongly agree").

Results

The athlete targets were perceived as more competent than the control target. The elite target was perceived as more competent than the recreational athlete. The facets analysis showed that all facets of the competence dimension were influenced in the same direction. Assertiveness was the facet which benefited the most from the information about the athlete status.

Concerning warmth, our results showed a negative effect of the athlete status. Athletes targets were perceived less warmth than the control target. The facets analysis showed that only the sociability facet was responsible for these differences in perceived warmth.

Discussion

Our study highlights the importance of taking into account the facets of warmth and competence in research on the exerciser stereotype as this may reveal hidden effects and help to understand how overall effects may occur.

By allowing the reduction of stigma and contributing to their empowerment, sport participation at different levels appears as a real strategic tool to improve the living conditions of PWPD in society. Thus, displaying one's athlete status could be used as a self-presentation strategy, especially in a professional context where PWPD are traditionally discriminated.

THE FAMILIES POINT OF VIEW: FROM EUROPE TO THE ITALIAN FOLLOW-UP OF THE IKONS PROJECT IN PEOPLE WITH INTELLECTUAL DISABILITY (ID)

SBRICCOLI, P., GIANCOLA, E., CAMOMILLA, V., QUINZI, F., VANNOZZI, G., VERDONE, F., PIACENTINI, M.F.

UNIVERSITY OF ROME

INTRODUCTION

The effectiveness of an adapted karate program in Down Syndrome individuals in terms of cognitive and coordinative function improvement has been demonstrated in the framework of a European project (IKONS). Thus, an additional analysis of the local contexts through online surveys was performed. The aim of the study was to collect information directly from the families about the impact of three months of training with the IKONS method in people with ID. The attention was focused on the impact of adapted karate training on their daily living, on the barriers they can find in practicing regular physical and/or sport activity and to which extent this activity is perceived as inclusive.

METHODS

The surveys of 45 family members of individuals with ID were collected and analyzed. The surveys were carried out by qualitative and quantitative research with the surveys administration before and after 3 months of adapted karate training. Respondents were supposed to answer questions regarding the Relationship between Users and Sport; aspects of Inclusiveness of Sport; Sports as an element supporting Autonomy; Activity Obstacles and Facilitator Elements; Effects of the project on Users. The surveys included closed (measured with the Likert Scale) and open-end questions. For the open-end questions, grouping tables were created for the responses, and this process generated different macro-areas, named differently for each question. The analysis was focused on defining facilitators and obstacles encountered in the past to participate in physical activity programs.

RESULTS

Before training, respondents declared many obstacles in practicing physical activity, such as the inadequacy of structures (23.5%), hostility towards disability by coaches and team-mates (29.4%), teachers not well prepared (5.9%), fear to relate with others (11.8%), distance and inconvenience (11.8%), unwillingness (11.8%), health problems (5.9%).

After training 100% of the respondents answered that expectations were satisfied, and 93.9% expressed their will to continue to participate to adapted karate classes. Socialization (46,7%) and sharing (20%) were classified as main determinants in attributing to sport activity a relevant role in the inclusion process. Moreover, 71.9% of respondents noticed improvements in motor coordination (28.6%), posture (14.3%), tonicity (9.5%), slimming (9.5%), elasticity (4.8%), agility (9.5%), more energy (9.5%), body awareness (9.5%), and stereotypies disappearance (4.8%).

CONCLUSIONS

The main finding of this study was that three months of adapted training for people with ID was perceived by family members as effective in increasing their quality of life, as well as in improving physical, relational and behavioral aspects. The families highlighted the concept of "Autonomies" resulting from participation in sports. Adapted physical activity is thus confirmed as a valuable tool in this population in a logic of inclusion, and equal opportunity.

INFUSING DISABILITY AWARENESS IN EDUCATIONAL SETTINGS THROUGH REVERSE INTEGRATION: EXPLORING STUDENTS' KNOWLEDGE AND PERCEPTIONS OF DISABILITY AND INCLUSION IN WHEELCHAIR BASKETBALL

OLDROYD, R.

NORTHUMBRIA UNIVERSITY, UK

Introduction: Students' knowledge and learning experiences within the field of sport, exercise and adapted physical activity will contribute to promoting physical activity and facilitate inclusive opportunities for disabled people. It is necessary for researchers and educators to understand and expand pedagogical approaches on how students acquire learning experiences and knowledge. By applying reverse integration, this paper explores a set of learning practices that can be considered and adapted in an educational setting. Through a collaborative design of practice between academic tutors and the lead researcher, the aim was to enhance students' knowledge and understanding of disability and inclusion.

Methods: The context of this study is a short educational course informed by disability studies perspectives focused on reverse integration. A qualitative analysis of the meanings from students' engagement and experience in a disability awareness workshop focused on reverse integration in wheelchair basketball. Fifty-three students were invited to attend a workshop which coincided with their module delivery and assessment at university. The students were invited to attend a lecture, a practical and a seminar across two days while actively engaging with national wheelchair basketball athletes. Questionnaires and informal recorded discussions were used to gain responses. A content analysis was conducted and reviewed, and all patterns, commonalities and student perceptions were noted.

Results: The data indicate that students before the course had limited knowledge and disability awareness in wheelchair basketball. During the course, the students found the practical element/reverse integration, by taking part in a wheelchair basketball session, had helped them to become more aware and have a sense of appreciation towards people who use a wheelchair daily and the strength that it involves to perform certain skills. After the course, once all lectures and practical's had taken place, the students shared they had gained much more knowledge about disabilities and overall felt more confident to work with, and engage with disabled athletes. Lastly, most students found that it was an invaluable experience and expressed that there should be more sports that include able-bodied and disabled people together as it helps to minimise and address certain barriers towards sport participation.

Discussion: In analysing the data it was apparent that the students expressed a meaningful shift in their thinking and their value of performance ability of disabled athletes and disability sports was much more of an appreciation towards their thinking around disabilities in sport. As a result, from the workshop, reverse integration in wheelchair basketball has contributed to changing perceptions of players with disabilities and their understanding of disabilities and inclusion. These insights have the capacity to influence educational settings and coach education pathways.

BIMANUAL FORCE CONTROL FEEDBACK USING LISSAJOUS PLOTS: HELPFUL OR IN THE WAY?

WEINRICH, M., WANG, Y., KENNEDY, D.M.

TEXAS A&M UNIVERSITY

INTRODUCTION: Many daily tasks require precise coordination between the left and right limb to achieve a given task goal. Augmented visual feedback (e.g., Lissajous) is commonly used in bimanual coordination research to help facilitate skill acquisition (Kovacs, et. al. 2010). Subjects are able to take advantage of the integrated feedback provided by the Lissajous plot reducing attentional demands and utilize trial-by-trial errors to meet the goal coordination pattern when performing bimanual coordination tasks (Kovacs et al., 2009; Kennedy, et. al, 2016). The accuracy of force production has often been less emphasized during Lissajous guided task. Therefore, the first objective of the current study is to investigate the accuracy of bimanual force production when performing bimanual isometric force coordination tasks; the second objective is to examine whether the strength of force production influences the accuracy of producing the goal bimanual coordination patterns.

METHODS: Nine participants produced the maximum voluntary contraction (MVC) via abduction isometric contractions against fixed force transducers using the first dorsal interossei (FDI) muscles. The MVC was used to set the target force of 10% and 30% of subjects MVC. All subjects were required to complete 2 different coordination patterns (0° & 180°) using four Lissajous feedbacks, at two different force goals (10% & 30% MVC). Subjects completed 112 trials total. Lissajous feedback included classic Lissajous (CL), overshoot feedback (OF), target feedback (TF), color feedback (CF).

RESULTS: For absolute error (AE) of relative phase there was a main effect of task (p=<.001) indicating there were more errors produced for the 180° task (44.88±11.93) compared to the 0° task (10.18±2.54). For variability of relative phase (VE) there was a main effect of feedback (p=0.041) suggesting that additional feedback (CL: 21.48±2.07 compared to TF:24.90±4.63, OF: 23.87±2.56, CF: 23.91±2.724) can cause greater amounts of variability of bimanual force coordination. For the 0° task, force accuracy data revealed a main effect of feedback (p=<.001) with the CF condition having a higher percent accuracy compared to the other feedback conditions(CF: 21.94±14.34 compared to CL: 5.49±4.78 ,TF: 17.04±11.13 ,OF: 18.82±11.16). For the 180° task significant main effect of feedback (OF: 44.83±22.98 compared to CL: 29.74±28.11 ,TF: 43.406±19.04 ,CF: 39.57±24.83) found that the OF condition has the highest force accuracy measures compared to the other feedback conditions.

CONCLUSION: The results indicated that force accuracy was significantly better in the 180° task compared to the 0° task. It has been demonstrated that unimanual performance is more accurate than bimanual force performance during isometric force coordination tasks. Suggesting inphase and antiphase require different control strategies when approaching maximal force level for each limb (Fling & Seidler, 2011).

EXPLORING THE DIFFERENTIAL EFFECT OF MOVEMENT DISTANCE AND TARGET WIDTH ON AVERAGE MOVEMENT VELOCITY

CHEN, C.H., LIU, Y.T.

NATIONAL TAIWAN NORMAL UNIVERSITY

INTRODUCTION: Fitts' Law has been used extensively in sport performance as the basis for investigating the movement speed and accuracy relation (1, 2). There are two parameters, movement distance (D) and target width (W), in the index of difficulty (ID) of Fitts' Law, and increasing D or decreasing W will lead to an increase in ID. Fitts' Law predicted that movement time (MT) increases as ID increases. There have been observations that although the movement average velocity (AV) decreased with increasing ID when W was manipulated, the AV increased with increasing ID when D was manipulated (3). The purpose of the study was to investigate the influence of Fitts' ID on MT and the AV when both D and W were manipulated simultaneously.

METHODS: Twelve participants performed the line drawing task in 7 sets of ID conditions (1.9, 2.7, 3.8, 4.8, 5.9, 6.9, 8.0 bits) each with different combinations of D and W (10/5.5, 15/4.5, 25/3.5, 35/2.5, 45/1.5, 55/0.9, 65/0.5). The order of ID conditions was chosen at random. All participants practiced 10 trials before the 20 testing trials in each condition. The goal of the task was to draw a horizontal line to the target as quickly as possible. If the participant failed more than 4 trials to stop within the target in a condition, the condition would be re-tested for 20 trials. The linear and nonlinear regressions were performed on the average MT and AV over the IDs, and the one-way repeated measures ANOVAs were used to examine the effect of ID on MT and AV.

RESULTS: The exponential fit for MT over IDs had the R^2 of 0.99 whereas the R^2 for the linear fit on MT was 0.86. The quadratic equation fit for AV over IDs had R^2 of 0.99. The ANOVA result on MT showed significant ID effect, $F(1.57,17.31) = 90.05$, $p<0.001$. ID also had significant effect on AV, $F(2.76, 30.33) = 36.51$, $p<0.001$, where the AVs of the 2 middle IDs were significantly higher than those of lower and higher IDs (ps<.001).

CONCLUSION: The Inverted U shape of AV over the increased IDs demonstrates the competing influence of D and W in ID when both parameters were manipulated. The Lower IDs were dominated by the effect of shorter Ds where increasing D resulted in an increase of AV, whereas at higher IDs, smaller Ws lead to the decrease of AV. There appeared to be critical values for D and W for the changes of AV over the increase of IDs. Systematic manipulations of sets of Ds and Ws to create ID conditions may reveal these critical values.

BALL OR NO BALL? DISTINGUISHING MOVEMENT COORDINATION OF ACTUAL VS SHADOW TABLE TENNIS STROKES

LIN, L.Y., LIU, Y.T.

NATIONAL TAIWAN NORMAL UNIVERSITY

INTRODUCTION: During games, table tennis players pick up the information from the coming ball and use it to intercept the ball with optimal timing. Oftentimes, players also perform the shadow play to supplement their training, practicing stroke movements without balls. However, based on the constraint model [1], the movement coordination and control of players would be different between actual stroke and shadow play. We proposed that movement patterns of action conditions could be differentiated through visual perception of different levels of players. This is due to the impressive visual sensitivity human observers have to human movement, which can then be selectively enhanced by extensive visual experience [2]. Thus, this study aimed at investigating the movement coordination between table tennis shadow stroke and actual stroke in visual perception.

METHODS: Observers of different levels of table tennis (skilled, n = 34; less skilled, n = 30; naive, n = 31) viewed videos under the point-light display and answered if the actor was hitting a ball in each video. Each observer watched 48 videos that consisted of 24 trials from three actors (skilled; less skilled; novice). Each actor repeated the actions in four sessions

(shadow play; robot launched at 1.7s interval; robot launched at 1.1s interval; a player hitting the ball back and forth with the actor) in forehand and backhand positions. The number of correct answers were converted to score rate (SR), and the consistency rate (CR) was calculated from the answers of the duplicate videos. In addition, the correct information rate (CIR) was estimated using the correct answers from the trials and their duplicates. Observer (3) X actor (3) mixed-design ANOVAs were performed on SR, CR, and CIR, with repeated measures on the effect of the actor.

RESULTS: Interactions between the observer and the actor of SR [$F(3.66, 168.43)=7.59$, $p<.05$] and CIR [$F(3.53, 162.18)=7.13$, $p<.05$] were significant, revealing that both skilled and less skilled observers were superior at picking up information for the novice actors videos compared to the less skilled actors ($ps<.05$). In addition, SR and CIR of the naive observers were lower than the skilled and less skilled observers ($ps<.05$) for the novice player's videos. No significant results were found on CR.

CONCLUSION: Our results provide evidence to support the constraint model which states that the movement pattern of striking a table tennis ball is different compared to that of shadow play. The skilled players were better at differentiating the movement patterns, suggesting that visual sensitivity to stroke patterns was enhanced by extensive experience of the players. Lastly, we suggest that coaches should reconsider the purpose and effect of shadow practice for the beginner players.

SPATIAL DISTRIBUTION AND ACTIVITY OF THE ERECTOR SPINAE MUSCLES IN CYCLISTS WITH RECENT HISTORY OF LOW BACK PAIN

SAMPIERI, A., MAGISTRELLI, E., MASARIN, A., PAOLI, A., MORO, T., MARCOLIN, G., CASOLO, A.

UNIVERSITY OF PADUA, ITALY

INTRODUCTION: Low back pain (LBP) is the most prevalent overuse injury in cycling, which accounts for ~58% of all musculoskeletal disorders (1). The pathomechanics is still unclear but potential major causes may include prolonged maintenance of forward trunk flexion, mechanical creep, high mechanical loads experienced during cycling, and overactivation of erector spinae (ES) muscles (2). Previous evidences on rowers with recent history of LBP reported an altered activation and spatial distribution of ES activity (3). Conversely, less is known about the specific lumbar region activation patterns in cyclists with LBP. Accordingly, we compared the spatial distribution of ES in cyclists with and without LBP using high-density surface electromyography (HDsEMG).

METHODS: Eighteen participants (age: 40.3±12.4 yr, body mass index: 22.9±1.6 Kg/m2) took part in this cross-sectional study. Based on their Oswestry Disability Index value (ODI-I, vr. 2.1a), they were assigned to either a LBP group (n=8, ODI-I score: 20.8±8.9%) or to an asymptomatic group (CG, n=10). Participants underwent an incremental cycling test, characterized by 4 bouts of 3-min at 70, 80, 90, and 100% of their functional threshold power (FTP), interspersed by a 2-min resting period. Concurrently, HDsEMG signals were recorded with 2 electrode-grids positioned on the ES muscles. The average normalized root-mean-square amplitude (RMS) and the y-axis coordinate of the barycenter of activation (RMS-map) were extracted and compared between sides, intensities, and groups.

RESULTS: The two groups displayed similar anthropometric characteristics and FTP values. No differences were observed in RMS amplitude with increasing loads and in both sides within each group. However, as the pedaling load increased, we observed a different RMS amplitude trend in ES activation between groups. In particular, the LBP group showed a significantly higher RMS amplitude in the right ES muscle at 100% FTP compared to the CG (142.3±63.1 vs. 93.3±24.7 %RMS; $p= 0.003$). In addition, LBP group exhibited a tendency to a caudal displacement of the ES activity as the load increased, which was not observed in the CG. However, the y-axis coordinate displacement did not differ between groups at each pedaling intensity.

CONCLUSION: This study provides new knowledge about lumbar ES muscles activity in cyclists with recent history of LBP. Our results suggest that LBP cyclists show a greater ES activation and a tendency to a caudal displacement of muscle activation at the highest pedaling intensities compared to healthy controls. Based on these preliminary results, we hypothesize that the observed altered activation of ES muscles in LBP cyclists may be confirmed by enlarging our sample size. Furthermore, future analyses should investigate whether the increased ES muscle activation is the cause or consequence of the LBP.

DESPITE LEFT-HEMISPHERE SPECIALIZATION IN MORE COMPLEX FINGER-TAPPING TASKS, HANDEDNESS DOES NOT AFFECT MOTOR SKILL ACQUISITION AND ITS INTERLIMB TRANSFER

NÉGYESI, J.

HUNGARIAN UNIVERSITY OF SPORTS SCIENCE

INTRODUCTION: Our previous results (Négyesi et al., Sci. Rep, 2022) suggested left-hemisphere specialization for motor sequencing tasks. Here we examined whether handedness interacts with motor sequencing tasks with different complexity levels immediately and 24h after motor sequence practice. We hypothesize further improvements in accuracy, reaction time (RT), and movement time (MT) 24h after the practice, however, the level of improvement might differ between left- (L) and right-handed (R) participants.

METHODS: Participants performed finger key presses on a numeric keyboard with each hand in separate trials at 4 different complexity levels using our custom-made software. We analyzed the accuracy, RT, and MT of each trial. Participants underwent a short-term dominant-hand motor sequence practice, and then the changes in the dependent variables were measured in both the trained and non-trained hands immediately and 24h after the practice. We supplemented our study with EEG recordings but the current abstract reports only the behavioral data.

RESULTS: Each analyses of MT revealed similar gross patterns of changes as RT (all $r>0.9$, $p<0.001$). In line with our previous study, both R and L performed the motor sequence task more accurately and with shorter RT and MT when using their right hand. However, these effects appeared only in tasks with higher complexity levels (R: Level 3: $p<0.001$, Cohen's effect size $d=0.744$; Level 4: $p=0.034$, $d=0.311$; L: Level 3: $p<0.001$, $d=0.805$. Level 4: $p=0.008$, $d=0.334$). Motor sequence practice produced a similar magnitude of motor skill acquisition and interlimb transfer immediately after the practice which further improved the next day (all $p\leq0.002$). However, the changes were independent of handedness.

CONCLUSION: Overall, our results indicate that left-hemisphere specialization for these tasks might be present only above a certain complexity level. On the other hand, handedness seems to have effects on motor skill acquisition or interlimb transfer neither in simple nor in more complex tasks. Lastly, in line with our hypothesis, dependent variables further improved the next day as compared to their immediately post-practice values, however, the changes in skill retention were independent of handedness.

THE CONTEXTUAL INTERFERENCE EFFECT ON RETENTION AND TRANSFER IN MOTOR LEARNING - A LABORATORY ARTIFACT?

CZYZ, S.H.1,2,3, WÓJCIK, A.M.1, SOLARSKA, P.2, KIPER, P.4

1 - WROCŁAW UNIVERSITY OF HEALTH AND SPORT SCIENCES, POLAND; 2 - MASARYK UNIVERSITY, BRNO, CZECHIA; 3 - NORTH-WEST UNIVERSITY, SOUTH AFRICA; 4 - AZIENDA ULSS 3 SERENISSIMA, VENEZIA, ITALIA

INTRODUCTION: Contextual interference (CI)(Battig, 1966) affect performance, retention, and transfer differently depending on whether the practice was scheduled in random or in blocked order. Random practice condition hinders performance during acquisition, although it facilitates retention and transfer, while blocked practice is supposed to have the opposite effect. Many publications have confirmed the CI effect since Shea and Morgans (1979) classical study on the CI effect in motor learning. In 2004, Brady published a meta-analysis concluding that the CI effect is conspicuous in motor learning in the laboratory but not in applied settings. Given the broad interest in the CI effect, we aimed to update the somewhat obsolete Brady's meta-analysis and re-analyze the results of independent studies on the CI effect.

METHODS: The study was registered in PROSPERO (CRD42021228267). The following databases were searched: Scopus, EBSCO, Web of Science, PsycINFO, and ScienceDirect, supplemented by the search engine Google Scholar. The quality assessment was done with the Quality Assessment Tool for Quantitative Studies (Thomas et al., 2004) including elements: sample selection, study design, identification of confounders, blinding, reliability and validity of data collection methods, withdrawals, and dropouts. These elements are rated as strong, moderate, or weak. Studies with two or more weak ratings are considered weak, those with less than four strong ratings and one weak rating are considered moderate, and, subsequently, studies with no weak ratings and at least four strong ratings are regarded as strong.

RESULTS: We found that most of the studies on CI in motor learning are of poor quality and are potentially biased, and the CI effect was more conspicuous in laboratory than in applied studies. 59 studies were included in the analysis on retention. Only three articles presented moderate or high quality. The analysis of studies on the CI effect on transfer yielded similar results: none out of 42 studies included in the review was assessed as strong and only two articles were assessed moderate. Twenty-six studies scored weak on the Selection Bias criteria.

CONCLUSION: It may be concluded that studies on CI may be biased. Therefore, the question initially asked by Al-Mustafa and re-asked by Brady (2004) has to be re-stated again: is "contextual interference a laboratory artifact or sport-skill related?

THE EFFECTS OF ACUTE EXERCISE ON CORTICAL HEMODYNAMICS DURING EARLY STAGES OF MOTOR MEMORY CONSOLIDATION: AN FNIRS STUDY

WANNER, P.1, WUESTENBERG, T.2, DOERR, M.1, HETTMANNSPERGER, M.1, HERRMANN, G.1, SPINDLER, L.1, ROIG, M.3, STEIB, S.1

<1> HEIDELBERG UNIVERSITY; <2> HEIDELBERG UNIVERSITY; <3> MCGILL UNIVERSITY

INTRODUCTION: Current studies suggest that a single bout of cardiovascular exercise enhances motor memory consolidation. With increasing number of experiments, however, the findings have become equivocal. Discrepancies have been debated to stem from differential effects of exercise on prefrontal and motor cortex activity potentially depending on cardiorespiratory fitness. Thus, the aim of the study was to investigate the effects of post-practice exercise on prefrontal and motor cortex activity during the early stages of motor memory consolidation.

METHODS: 14 healthy males (24.1±3.1 yrs) participated in a counterbalanced within-subject design. At study enrollment peak oxygen consumption (VO2peak) was assessed in a graded exercise test to determine cardiorespiratory fitness. During the main experiment participants practiced an explicit motor sequence learning task followed by either (i) high-intensity interval exercise at 90%/60% Wmax (EXE), or (ii) seated rest (REST). Resting-state prefrontal and motor cortex activity was measured using functional near-infrared spectroscopy (fNIRS) before as well as 10, 30, and 60 min after EXE or REST. Consolidation was tested in a retention test 24 h later. Changes in prefrontal and motor cortex activity as well as normalized differences between cortical areas were analyzed using separate 3 (time) x 2 (condition) repeated-measures ANOVA. Paired t-test was used to examine memory consolidation (i.e. percent skill change from end of practice to retention test). Potential associations between consolidation, cortex activity, and VO2peak were tested using Pearson's correlation.

RESULTS: EXE resulted in a significant higher activity of the prefrontal ($F_{1,13} = 22.134$; $p < .001$) and motor cortex ($F_{1,13} = 31.941$; $p < .001$) compared to REST, while the difference between cortical areas indicated a greater increase of prefrontal cortex activity ($F_{1,13} = 8.546$; $p = .012$). EXE did not significantly improve memory consolidation ($t(13) = -0.291$; $p = .775$). Pearson correlation suggested no significant relation between global exercise-induced changes in cortex activity and consolidation (prefrontal: $r = -.073$, $p = .805$; motor: $r = -0.199$, $p = .496$) or VO2peak (prefrontal: $r = -.296$, $p = .305$; motor: $r = -0.085$, $p = .773$). However, separate analysis of participants with lower fitness (i.e. median-split of VO2peak) revealed a significant negative correlation between changes in prefrontal-motor cortex difference and VO2peak ($r = -.841$, $p = .018$) indicating a greater activity shift to the prefrontal cortex in lower fit participants.

CONCLUSION: Our results confirm an exercise-induced increase of prefrontal and motor cortex activity during early stages of consolidation with a greater increase in prefrontal cortex activity. Interestingly, this activity shift to the prefrontal cortex appears to be more pronounced in participants with lower cardiorespiratory fitness. These findings provide further insights into the differential effects of exercise on the prefrontal and motor cortex.

CAN HAND GRIP FORCE BE A PREDICTOR OF MOTOR COMPETENCE?

GISLADOTTIR, T., PETROVIC, M.

UNIVERSITY OF ICELAND

INTRODUCTION: Motor competence (MC) in children and adolescents may be an essential correlate of subsequent physical activity and the development and maintenance of physical fitness (Hardy et al., 2012; Stodden et al., 2009). MC can be conceptualized as the person´s ability to perform different movements, including both gross and fine motor skills. Hand grip force is found to be positively related to other muscle groups. The hand grip force also presents an indicator for valid evaluation of the overall body strength (Bohannon, 2001). The aim of this study was to investigate the association between hand grip force and motor competence in adolescents.

METHODS: Data from 210 boys (mean age: 13.6±1.1 years; body height: 167±1.1cm, body weight: 59.1±14.2 kg) and 177 girls (mean age: 13.4±1.1 years; body height: 161±0.9cm, body weight: 55.1±12.4 kg) were used in this study. The Movement Assessment Battery for children-2 (MABC-2) was used as an objective measurement of adolescents motor competence. The MABC-2 provides an assessment of gross and fine motor coordination and is designed for the age group from 13-16 years. The test consists of three tasks measuring manual dexterity, two tasks measuring ball skills, and three tasks measuring balance. Hand grip force was measured by a hand dynamometer with an adjustable grip. Correlations between the hand grip force and MABC-2 tests, for both girls and boys, were obtained by calculating Pearson's correlation from Jamovi software.

RESULTS: In girls, no significant correlations were found between hand grip force and MABC-2 tests. The only significant correlation, although weak, in boys, was observed between hand grip force and two tasks measuring ball skills, i.e., aiming & catching ($r=0.255$; $p=0.001$).

CONCLUSION: In the present study, results indicate that hand grip force was not correlated with motor competence. It can be explained in part by the fact that the component of the MABC-2 test includes fine motor skills where maximal strength does not play a relevant role. Moreover, even though gross motor skills rely more on strength, no correlation was found between grip strength and gross motor skills tasks in the MABC-2 test, except for a weak correlation between aiming and catching in boys. Grip strength is not an accurate predictor of motor competence.

The current study was conducted in a specific country (Iceland); hence, cross-cultural generalization of the findings is limited. Future studies should consider the development of gender differences from a long-term perspective, and in that sense, longitudinal studies could give better explanations.

FREQUENCY-DEPENDENT LEARNING EFFECTS OF THE BIMANUAL FIVE-DAY TRAINING

AZUMA-TAKESHITA, K., MIYATA, K., KUDO, K.

GRADUATE SCHOOL OF ARTS AND SCIENCES, THE UNIVERSITY OF TOKYO

INTRODUCTION: From daily life to sports performance, skilled experts can properly coordinate limbs both temporally and spatially to fulfill specific purposes. Professional drummers could maintain bimanual coordination accurately in an anti-phase pattern with maximum speed, while novices tended to be away from an anti-phase to an in-phase pattern (1). Since certain skillful performances need to coordinate in an anti-phase, an enormous effort is needed to obtain the coordination skill. In other words, experts have been exposed to a variety of movement conditions throughout the practice, and we assume that one of them is movement tempi. Therefore, we set the different training frequencies based on participants' inter-limb coordination profiles and investigated whether the training frequency affects the stability of performance or not.

METHODS: A total of 30 participants were divided into three groups, Group1, 2, and 3, who had engaged in five-day training of index fingers' flexion-extension in anti-phase mode at allocated frequencies. Before and after the training session, they performed the repetitive flexion-extension movement of the index fingers in anti-phase mode continuously with increasing metronome frequency by 16 beats from 60 to 260 beats per minute (bpm), then in-phase maximum trials for 10 sec. From recorded movies at 120 Hz, the coordinates of anatomical landmarks of both hands were extracted using DeepLabCut. The flexion angles of the index fingers and the relative phase between both hands were calculated. Since the relative phase of the anti-phase mode means 180 degrees, we calculated the root mean square (RMS) using the absolute errors of the relative phase from 180 degrees to evaluate the coordination performance. We assigned the training frequency for each participant based on the results of the trials before the training; 60 bpm for Group 1, the bpm over twice from RMS at 60 bpm for Group 2 (168 ± 47.3 bpm), and the averaged bpm of both hands at in-phase maximum trials for Group 3 (314 ± 32.7 bpm). A three-way ANOVA was performed on the RMS (Training pre/post, 11 bpm, and 3 Groups).

RESULTS: Although the three-way interaction of RMS was not significant, $F(7.45, 100.63) = 1.451$, $p = 0.19$, the main effects of the training and the bpm were significant, $F(1, 27) = 14.138$, $p < .001$, $F(2.53, 68.44) = 108.278$, $p < .001$, respectively. To compare the training effect on RMS at training frequency, we subtracted the RMS of pre from that of the post; -5.1 ± 7.0, -27.8 ± 35.8, and -14.8 ± 17.1 degrees, respectively.

CONCLUSION: Our findings showed that the learning effect of the five-day anti-phase movement training was not differentiated among individual frequency conditions, while the general improving effect on movement stability was evident. Therefore, further studies on training conditions including intensity, duration, or term are needed to elucidate the potential specific effects of the training.

THE EFFECT OF AN ACUTE BOUT OF PHYSICAL AND COGNITIVE EXERCISE ON EXPLICIT SEQUENTIAL MOTOR LEARNING

DIGONET, G., LAPOLE, T., POUILLOUX, G., DEBARNOT, U.

UNIVERSITY CLAUDE BERNARD

INTRODUCTION: Sequential motor learning is characterized by at least two distinct phases: a fast, online acquisition stage followed by a slow, offline consolidation process. Recent findings revealed that an acute physical exercise (PHY) before implicit motor learning promoted online and offline gains in performance as compared to no exercise. The physiological cascade induced by PHY may facilitate the activity-dependent neuroplasticity associated to motor acquisition and in turn consolidation. Similar findings have been observed on implicit motor learning but following cognitive exercise (COG). It is well-known that the nature of motor skill acquisition, either explicit/conscious or implicitly/unconscious, involves different neural substrates. Up to know, whether PHY and COG inductions before explicit sequential motor learning have been understudied. Therefore, we investigated the effect of PHY and COG inductions separately on explicit sequential motor acquisition and consolidation, and further explored their combined effects.

METHODS: To date 36 out of 48 expected participants were enrolled in this study. Participants were asked to perform either PHY (15 8-s sprints), COG (Time load Dual-back task), combined PHYCOG or a no-exercise (CTRL) condition prior sequential motor acquisition. The effectiveness of PHY and COG inductions was assessed by means of objective lactate collections and subjective NASA-TLX (i.e. cognitive and physical workload perception). Each induction type lasted 20 min, and then participants trained on the explicit sequential finger movement. Motor performance was evaluated before and after online training (i.e. acquisition), and following offline 24 h and 7 days delays (i.e. consolidation).

RESULTS: There was an increase in lactate concentration right after PHY and PHYCOG ($p < 0.001$) inductions, as compared to COG and CTRL. Subjective mental demand raised after COG and PHYCOG inductions relative to PHY and CTRL ($p < 0.001$). Other than the aforementioned findings, there was no other differences between groups. We observed an improvement of performance during acquisition ($p < 0.01$) whereas performance remained unchanged across consolidation (no further offline effect; $p = 0.68$).

CONCLUSION: Overall, the objective and subjective effects of mental and physical inductions have been effective as revealed by the modulations of lactate concentration and subjective measure of mental demand. These preliminary findings, with underpowered statistical analysis according to the small sample size, preclude any conclusion on the effect of PHY and COG inductions on explicit motor skill acquisition and consolidation. Data collection is ongoing.

EFFECTS OF A REPEATED HIGH-INTENSITY EFFORTS TRAINING COMPARED TO REPEATED SPRINT TRAINING ON REPEATED HIGH INTENSITY EFFORT ABILITY AND IN GAME PERFORMANCE IN PROFESSIONAL RUGBY UNION PLAYERS.

PAUL, G.

UNIVERSITÉ LYON 1

INTRODUCTION: This study investigated the effects of a repeated high-intensity efforts (RHIE) training compared to repeated sprint exercises (RSE) training on repeated high-intensity effort ability (RHIEa) and in-game performance in professional rugby union players. In recent decades, the ability to repeat sprints has been considered as a major determinant of performance in team sports. However, rugby union is not only characterized by repetitions of running phases, but also by contact efforts.

Therefore, an evolution of the RSa concept has been proposed in rugby union: the Repeated-High-Intensity Exercises ability (RHIEa). RHIE have been defined as a sequence of three or more intense efforts interspersed with less than 21 s of recovery between each. Thus, in rugby union, the ability of a player to repeat RHIE bouts is considered as a crucial element and appears to be more relevant than the RSa for measuring performance. The high-intensity repetition training programs based on sprinting (RSE training) and based on alternating high-intensity running and contact efforts (RHIE training) generate specific adaptations on RSa and RHIEa, respectively. However, the efficiency of these methods for developing RHIEa has never been compared, and it still unknown whether these training methods differentially impact in-game efforts in rugby union.

METHODS: Thirty nine male rugby union players (age, 26.4 ± 4.2 years ; height, 184.4 ± 7.6 cm; body mass, 97.2 ± 15.5 kg; 4 skinfolds body fat, 15.7 ± 4.1 %) from French second professional division were distributed into three training groups (RHIE training, RSE training, and Control groups). RHIE ability and high-intensity efforts characteristics during official games were assessed before (Pre-training) and after (Post-training) a ten-weeks specific (RHIE, RSE or control) training period.

RESULTS: Concerning RHIEa, both RHIE training and RSE training led to significant improvements in average sprint velocity ($p < 0.001$), average sled push velocity ($p < 0.018$) and RHIE score ($p < 0.001$). However, gains in average sprint velocity were higher in RSE group (+ 4.1 + 2.6 %) while gains in average sled push velocity were higher in RHIE group (+ 8.1 + 5.5 %). Concerning high-intensity efforts in game, while both groups showed significant improvements in total distance, accelerations and contact rate, the number of sprints was higher in RSE group ($p<0.001$). Conversely, increase in contact rate was higher in RHIE (+ 40.5 + 18.3%) compared to RSE (+ 11.13 + 8.2 %, $p<0.001$) group and CONT group (-7.8 + 8.5%, $p<0.001$).

CONCLUSION: These results suggest that both RSE and RHIE training are effective methods to develop RHIEa and athletic performance in professional rugby union games. As the gains of certain abilities and game performance data differ depending on the chosen training method, we suggest that coaches may choose the most appropriate method according to the type of player, their position, and according to the style of play they want to develop.

PHYSICAL PERFORMANCE OF AMERICAN FOOTBALL PLAYERS: THE ROLE OF CHRONOTYPE

MULÈ, A., CIORCIARI, A., GALASSO, L., CASTELLI, L., ESPOSITO, F., MONTARULI, A., ROVEDA, E.

UNIVERSITY OF MILAN

INTRODUCTION: Several differences existing between individuals are related to the different expression of the circadian rhythmicity of biological functions. This inter-individuality allows to distinguish three chronotypes: Morning-, Neither- and Evening-types (MT, NT and ET) [1]. MT and ET differ in sleep-wake timing and mental/physical activation, with an early peak in the MT. NT have intermediate characteristics. Despite several studies showed a chronotype influence on sports performance [2], no one investigated them in the American football game. The study aimed to verify if the physical performances of American football players differ in relation to the chronotype, also considering the time of day in which the tests are performed.

METHODS: Athletes filled out the Morningness-Eveningness Questionnaire to evaluate their chronotype. After, they performed 4 physical tests: 40 yards (40y), 3-Cone drill (3Cd), two-Armed Shot Put (2-ASP), and Broad Jump (BJ), in order to evaluate different physical abilities: speed/acceleration, agility, arms and legs power respectively. The tests were carried out in the morning (8:30-10:00 am) and in the evening (8:30-10:00 pm), on two different days and with 3-4 day break.

RESULTS: 43 male athletes were recruited (21.8 ± 4.6 years). The sample consisted of 12% (n=5) MT, 60.5% (n=26) NT, and 27.9% (n=12) ET. Comparing the three chronotypes in each test session, no differences were found between them. The time of day in which the tests were carried out influenced the sports performance in ET and NT. MT showed no difference in performance between the morning and evening sessions, possibly due to the small number of participants. ET performed better in the evening session than in the morning for all tests (40y: 5.4 ± 0.3 vs 5.3 ± 0.2 sec., p=0.001; 3Cd: 5.4 ± 0.3 vs 5.2 ± 0.2 sec., p=0.005; 2-ASP: 5.1 ± 0.5 vs 5.2 ± 0.5 m., p=0.001; BJ: 2.1 ± 0.2 vs 2.2 ± 0.2 m., p=0.016; morning vs evening sessions respectively). NT performed better in the evening than in the morning: 3Cd (5.2 ± 0.2 vs 5.1 ± 0.2 sec., p=0.013), 2-ASP (5.2 ± 0.4 vs 5.3 ± 0.5 m., p=0.042), and BJ (2.2 ± 0.2 vs 2.3 ± 0.2 m., p=0.004). A trend of improvement in performance during the evening session was found for 40y in NT (5.40 ± 0.2 vs 5.36 ± 0.2 sec., p=0.06).

CONCLUSION: Based on this evidence, we can assume that chronotype is able to influence the performance of American football athletes, in relation to the times of the day in which the tests take place. This provides useful information for coaches, and personal trainers to consider when evaluating the football athletes performance and in planning their workout, in order to obtain the maximum benefits from the training.

DIFFERENCES IN PHYSICAL FITNESS AND TECHNICAL-TACTICAL PERFORMANCE IN ELITE, SUB-ELITE, AND NON-ELITE YOUTH MALE SOCCER PLAYERS

KOUDELLIS, M., TSOULOUPAS, C., APHAMIS, G., CHRISTOU, M., BOGDANIS, G., GIANNAKI, C.

UNIVERSITY OF NICOSIA

INTRODUCTION: Successful match performance depends on the interaction of physical, psychosocial, technical and tactical qualities [1]. Such characteristics influence the players selection by the coaches (i.e. elite vs. non-elite players) in the youth categories. [2, 3]. The primary aim of the current study was to examine the differences in physical fitness between elite, sub-elite and non-elite youth male soccer players . The secondary aim was to investigate the association between physical fitness and technical-tactical performance.

METHODS: Two-hundred forty-three young male soccer players (16-17 years) participated in this study. The physical fitness parameters assessed included cardiorespiratory fitness (VAMEVAL test), countermovement jump test (CMJ), 10 and 40 m sprints, and the Illinois agility test. Skinfolds measurement was used to estimate body fat. Technical and tactical data were recorded during a competitive soccer match using a multicamera, semiautomatic optical tracking system (InStat Fitness, Instat Limited, Limerick, Republic of Ireland). The InStat index was considered an index of technical-tactical performance.

RESULTS: Body fat percentage was significantly higher in the non-elite players compared to the sub-elite and elite players. Between groups differences were observed in the VAMEVAL test CMJ, 10 m sprint and agility, with the elite players demonstrating superior performance in all the tests compared to the sub-elite and the non-elite players. Also, the elite and sub-elite players had faster 40m sprints than the non-elite players. Technical-tactical performance (as expressed by the InStat index) was significantly better in the elite group compared to the sub-elite and the non-elite players (216.8±28.4 vs 170.5±20.6 vs 154.9±31.5; $p < 0.050$). A moderate correlation was found between the InStat index and 10m sprint ($r = -0.578$, $p < 0.001$), and strong correlations were found between the InStat index and CMJ ($r = 0.616$, $p < 0.001$), 40m sprint ($r = -0.610$, $p < 0.001$), agility ($r = -0.669$, $p < 0.001$) and cardiorespiratory fitness ($r = 0.609$, $p < 0.001$).

CONCLUSION: Elite youth soccer players performed significantly better in the physical fitness and technical-tactical performance compared to their sub-elite and non-elite peers. Moreover, physical fitness parameters correlated with technical-tactical performance during competitive matches. Taking all into account, physical fitness in youth soccer players should receive special attention as this appears to affect both technical and tactical performance.

EXPLORING POSSESSION-BASED PERFORMANCE INDICATORS IN DIFFERENT LEVELS OF BASKETBALL

LAN, Y.C.1, LIU, Y.T.2

1> NATIONAL YANG-MING CHIAO-TUNG UNIVERSITY , 2> NATIONAL TAIWAN NORMAL UNIVERSITY

INTRODUCTION: Basketball possessions are the foundations for scoring. The number of possessions in a game reflects the pace of the game and opposing teams tend to have similar number of possessions in a game. Therefore, possessions provide a useful basis for evaluating the effectiveness of team performances. Possession efficiency (PE) is the percentage of possessions that have at least one field goal attempt. Floor percentage (FP) is the percentage of possessions that have at least scored 1 point. Both are considered the offensive performance indicators. The recovered balls per ball possession (RB), calculated as the ratio of the sum of the steals, opponents turnovers, and fractions of blocked shots to the total of the possessions, reflects the defensive performances. The purpose of the study was to analyze PE, FP, RB, and the proportion (λ) of blocks that turned possessions, between winning and losing teams in different levels of basketball.

METHODS: We analyzed 150 games of the 2020~2021NBA (30 games from the playoff), 92 games of the 2019FIBA men's World Cup (FIBA) (48 games from the preliminaries), and 56 games of the 2021FIBA Under-19 World Cup (U19) (24 games from the preliminaries). Two independent observers recorded data from two games that were not part of the study for reliability testing. Cohen's Kappas were 0.92 and 0.9 for the intra- and inter-observer reliability, respectively. Data was recorded for 298 games by one principal observer. Outcome (2) by stage (2) mixed design MANOVAs were used to analyze the three possession variables for the NBA, FIBA, and U19 games. Additional one-way ANOVA was used to analyze the proportion (λ) of blocks that turned possessions among the 3 groups of games.

RESULTS: The winners had significantly higher FP than the losers in all 3 groups (ps <.001). A similar trend was also observed on the RB for the NBA, U19, and the preliminary stage of FIBA games (ps < .05). The stage effect on RB was also significant for the 3 groups, and the rate was higher at the advanced stage for U19, while the opposite was true of the other two groups. For PE, the advanced stage of the FIBA showed significantly higher rate than the preliminary stage, (p<.001). Lastly, there was a significant group effect on λ (p<0.001) where both NBA (0.71) and FIBA (0.64) were significantly higher than U19 (0.48).

CONCLUSION: The higher rates of FP and RB of the winners demonstrate that the data derived from possessions not only serve as the indicator for offensive performance, but also for the defensive performance. In addition, the increasing possession converting rate of blocks from less than 50% in U19 to over 70% in NBA seems to suggest that blocking is an important defensive tactic that not only prevents scoring by the opponent, but also allows a greater degree of recovering the ball possession in high level basketball.

CALLING AT WORK: ILLUMINATING ONESELF AND ACHIEVING OTHERS

LIN, S.

NATIONAL PINGTUNG UNIVERSITY

Introduction

School sports coaches play a critically important role in youth sports. They listen, motivate, support, encourage, and challenge young student-athletes. Therefore, how to enhance job performance among school sports coaches is important. A number of studies have demonstrated that employees with a higher level of work engagement would produce a higher level of work performance. The job demands-resources model (JD-R model) is a well-established theory and it has been widely applied in predicting health and workplace outcomes. The core concepts of the JD-R model are negative and positive job performance arose from job demands and job resources, respectively. In addition, studies have indicated that calling may be seen as a kind of resource in the workplace and would buffer the stress of job demands and intensify personal motivation at work. Hence, this study examined the moderating role of calling among school sports coaches on the relationship between work engagement and job performance with the JD-R model.

Methods

Cross-sectional data in the form of a questionnaire were collected from 192 school sports coaches. Except for the demographic data of the participants, the measures of the focal variables in the study adopted scales from published research with appropriate reliability and validity. All of the Cronbach's alpha values in this study were above .7, indicating adequate reliability.

Results

Work engagement and calling were standardized to examine the interaction effect on job performance. The results of hierarchical regression analyses showed that the main effects of work engagement positively and significantly predict job performance, and the interaction between work engagement and calling positively moderates job performance.

Discussion

The findings in the study revealed that the higher the work engagement of school sports coaches, the better their job performance. And the higher the calling of school sports coaches, the stronger the relationship between their work engagement and job performance. Our findings correspond with previous studies that employees with high work engagement are more energetic and enthusiastic regarding their jobs, which could lead to increased individual and team performance. In addition, calling-oriented employees consider working an intrinsic source of personal meaning and a means to fulfill the value of helping others. Previous researchers have considered calling the "climate for engagement",

where employees are more likely to respond by investing time and energy and by being psychologically involved in their work, which in turn leads to better performance at work.

DUAL CAREER - TUG OF WAR BETWEEN ELITE SPORTS AND VOCATIONAL SCHOOLING

RATZLAFF, L.1, SPEER, A.1, WULFF, H.2, WAGNER, P.1
1 UNIVERSITY OF LEIPZIG, 2 UNIVERSITY OF POTSDAM

Introduction

In secondary school settings, dual career support services exist almost exclusively for high school students [1]. For vocational schools, less is known about students' challenges particularly resulting of school-based and vocational education and participation in elite sports (ES). The research project comprises an adjusted curricular framework to promote a dual career at a vocationally-oriented school for the first time nationwide. It includes a two-year extension of school time period and is focused on reducing the double load of requirements. Thus, the aim of the study was to evaluate the curricular framework's effects on daily school and exercise routines of ES students.

Methods

Between 2016-2022, N=160 ES students and N=171 regular students participated in evaluation program. Based on annual standardized questionnaires students were asked about their management of time resources, satisfaction with various support services and their academic and sports performance development (1="very dissatisfied" to 6="very satisfied"). Additionally, teachers' and coaches' point of view derived from interviews. All regular students were used as a control group. Data were analyzed descriptively based on mean and standard deviation. To calculate between-group-effects an independent t-test ($p<0.05$) was used.

Results

Descriptive analyses resulted that ES students have a higher workload due to athletic training (9.1±0.9 training sessions per week) in addition to daily study time. The organized support service of exemption from lessons was used significantly more by ES students than by the control group ($p<0.001$) and was rated higher with regard to satisfaction ($p=0.007$). Furthermore, ES students were "rather satisfied" with school routines (4.6±0.8). At the end of their school time, ES students rated satisfaction with their academic (4.3±1.0) and sports performance (4.4±1.1) development nearly the same. However, there were no significant differences in ratings of satisfaction with academic development between both groups ($p=0.964$). Overall, ES students were "fairly satisfied" with the extended school time period (5.2±0.9).

Discussion

Despite the double burden, there is a high level of overall satisfaction among the ES students with their academic and sports performance development. Special support services could help ES students coping with daily requirements at the vocationally-oriented school. The positive evaluation of the school routines reflects the structured organization and implementation of the adjustments in school time. According corona-related experiences, the increased application of digital teaching tools should lead to higher flexibility in everyday school life and support the offer to promote a dual career.

A QUALITATIVE ANALYSIS OF THE PROCESS OF COACHING EXPERTISE OF EXPERT COACHES FROM AN UNLEARNING PERSPECTIVE

KITAMURA, K.
NIHON UNIVERSITY

Introduction

It is difficult for instructors to become proficient simply by accumulating coaching experience. Unlearning, in which one looks back on ones own experiences from a meta-perspective and repeats contemplation, is indispensable. For this purpose, it is important to have an opportunity to question ones own current situation and a cycle of repeated experience of exploration and contemplation from a meta-perspective. However, there is insufficient accumulation of empirical research on specific strategies and practices of unlearning in actual instructional settings. This study focuses on the unlearning experiences of expert instructors and aims to clarify how unlearning works in their development as instructors through qualitative analysis.

Method

Eight Japanese expert coaches were selected as participants. The participant selection criteria were: 1) highly regarded for their coaching practices, 2) proven track record of developing outstanding players, and more than 10 years of coaching experience. Semi-structured, open-ended, in-depth interviews were used for data collection. Interviews lasted approximately 90 minutes. During the interview, participants were informed that their cooperation in the study was voluntary, that they could refuse or withdraw at any time, and that anonymized data would be used. Consent to use personal information for research purposes was obtained under ethical considerations. Interviews were systematically transcribed verbatim from IC recorders immediately after each interview. Analysis was conducted by qualitative analytical methods using inductive procedures.

Results

A total of 126 meaning units were collected as a result of the data analysis. They were composed of the subcategories "diversely know," "diversely understand," "diversely able," "discover unknown," "notice unknown," "notice not possible," "want to know more," and "convince." These subcategories were further divided into the categories of "experience of noticing discomfort," "understanding from diverse angles," and "pursuit of further questions."

Discussion

While the expert instructors who were the participants of this study formed beliefs about their own coaching and increased their confidence as they accumulated coaching experience, they also had an awareness of the problem of constantly questioning and questioning their own coaching behavior. It was inferred that the diffuse thinking style, which creates a learning loop of repeated questioning and verification of fixed beliefs about ones own coaching style, is critically important in the process of instructional mastery. In addition, it became clear that by involving further diffuse thinking styles based on unlearned experiences in such a learning loop, it is possible to generate a new learning loop and promote proficiency. Such double-loop learning is thought to have led to the occurrence of unlearning experiences.

INVESTIGATING CORTICAL HAEMODYNAMIC AND PHYSIOLOGICAL CORRELATES OF EXERCISE COGNITION IN TRAINED AND UNTRAINED CYCLISTS OVER AN INCREMENTAL SELF-PACED PERFORMANCE TEST, WHILE THINKING ALOUD

ROBINSON, N.J., MONTGOMERY, C., SWETTENHAM, L., WHITEHEAD, A.

LIVERPOOL JOHN MOORES UNIVERSITY

Objectives: Few studies have directly investigated changes in cortical haemodynamics during a self-paced interval endurance activity, while collecting conscious cognition and physiological performance data. This pilot study used functional Near Infrared Spectroscopy (fNIRS), while capturing conscious cognition using Think Aloud (TA) during an incremental paced cycling exercise.

Methods: A mixed design was implemented with cycling expertise (untrained vs. trained) as the between groups variable and incremental self-paced stage (5 stages of increasing effort) and site (12 optodes across the PFC) as the within groups variables. Dependent measures were the changes in cortical O2Hb, and physiological indicators (% heart rate max (%HRmax), average power output (APO), peak power output (PPO), rate of perceived exertion (RPE) and blood lactate (Bla)) over time. Participants used TA throughout their second interval trial.

Results: Trained cyclists had higher APO and maximum power output (MPO) from stages 2–5, in addition to a greater increase in PPO over the whole trial. There were significant main effects of stage on %HRmax, Bla and RPE. Differences in cortical haemodynamics were found specifically in areas in the mid left and right PFC. TA

data demonstrated that untrained participants verbalised more irrelevant information and feelings of pain and fatigue, in addition to both groups verbalising significantly more motivation-related thoughts during the final stage.

Conclusion: This pilot is the first to capture changes in Cox, physiological measures and conscious cognition through the use of TA. We demonstrate the potential role of mid- PFC, and how conscious cognition may change over time. This study has implications for coaches and sport psychologists who may want to understand the

cognitions of their athlete during an event and support low level athletes in developing a better understanding of the own cognitions.

EFFECTS OF LIFE-SKILLS DEVELOPMENT PROGRAM INTERVENTION ON YOUNG ELITE FEMALE FOOTBALLERS

HORINO, H.

WASEDA UNIVERSITY

INTRODUCTION: Researchers have stated that life-skills are important in positive youth development. Life-skills Development Program (LSP) is revealed to be one of the essential components for the positive youth development framework. However, few studies have applied Life-Skills Development Interventions to Young elite athletes. We reported the results of LSP for three years to young elite women footballers. The objective of this study was to investigate the effect of LSD, for three years, on athletes' psychological competitive abilities on young elite athletes.

METHODS: Eighty-one female young footballers of elite academy in Japan, aged 13 to 15yrs, participated in the LSP for three years. the LSP was age-specific and consisted of several group-work lessons designed to develop psychological skills (goal setting, emotion control, self-recognition, empathy with colleagues, decision making, problem-solving, management for stress, leadership and career planning). The LSP was delivered to players in the classroom of their dormitory every other month. To assess their psychological skills, two questionnaires of life-skills were conducted about the daily life and the sport domain before and after the intervention.

RESULTS: Wilcoxon signed-rank test were performed for the changes on both scores before and after the LSP. The scores of both scales in the two questionnaires significantly increased after the LSP(life-skills of Daily life: $Z=4.13$, $p<0.001$; Life-skills of sport domain: $Z=3.368$, $p<0.001$. Scores for several factors also improved after the intervention.

CONCLUSION: Our results showed that the continuous intervention of the LSP had positive impacts on the psychological development of young elite athletes in both domains of "Daily life" and "Sport field". This finding revealed that LSP could enhance athletes' psychological skills in the athletic field. The results also showed that our LSP also had little impact on participants about several factors. Therefore, it is also suggested that we need to improve our context of the LSP. To

achieve more effective intervention, practitioners of the youth development framework need to develop programs that adopt practical context based on their sport field.

TWELVE-WEEK LASTING OTAGO EXERCISE PROGRAM PROMOTED THE ELDERLY'S MOBILITY AND NEURAL FUNCTION WITH CORRELATION IN SPECIFIC BRAIN AREAS: A RANDOMIZED CONTROLLED TRAIL

ZHENG, M.

TSINGHUA UNIVERSITY

INTRODUCTION: Physical exercise has become a widely recommended training method to reverse the decline of older adults' mobility and cognition, of which the Otago Exercise Program (OEP) was designed to get rid of falls effectively[1]. OEP was featured with medium intensity, mild training movements, and well-combination with the elderly's daily activities, thus could improve elderly's mobility and prevent risks. The neurological mechanics of this kind of physical training have not been further explored yet, so the presented abstract focus on disclosing the changes of brain structure and functional connection after the physical training. Furthermore, this study aims to find some correlations between behavioral promotion and functional changes of the brain after the intervention.

METHODS: Thirty-five older adults (age: 64±6, female:43%) were randomly divided into exercise intervention group (EIG) and control group (CG), receiving intervention for 12 weeks, respectively. EIG took part in OEP with two sessions, the muscle strength and balance training (30 min each time; twice a week), and walking more in their daily life (30 min each time, 3 times a week). EIG, for total, received 720 min functional training and 1080 min daily physical activities thoughout the intervention. CG just kept their lifestyle and was not required to do exercises. The structural and resting state functional MRI data (fALFF, ReHo, and DC) before and after the intervention were obtained and analyzed, in connection with behavioral mobility measures (grip strength, 30-s chair-stand test, single leg station with eyes closed, and timed up go).

RESULTS: Physical exercises could improve the participants' 30-s chair-stand test, single leg station with eyes closed, and timed up go performances. EIG showed increased fALFF in the posterior central gyrus and superior temporal gyrus (Z=4.17), and central front gyrus (Z=3.55). EIG also showed increased DC in the dorsolateral prefrontal lobe and dorsal medial prefrontal lobe (Z=4.02). While CG showed no significant changes in the mobility measures after the intervention. Additionally, the change of EIG's 30-s chair-stand test is significantly correlated with ReHo in the left putamen, while the EIG's performance of "timed up go" can predict ReHo in the left caudate and the right insula.

CONCLUSION: Physical exercises adopting OEP could improve the elderly's mobility, and the exercise intervention might promote the elderly's mobility through regulating the sensorimotor cortex. Moreover, the correlation between mobility promotion and specific brain areas' MRI measurements could predict some neural changes of the brain structure and function.

THE EFFECTS OF EXERCISE SNACKING AND TAI-CHI ON MUSCLE ACTIVATION AND PHYSICAL ACTIVITY IN OLDER ADULTS

LIANG, I.J., MCGUIGAN, M.P., PERKIN, O.J., THOMPSON, D., WESTERN, M.J.

UNIVERSITY OF BATH

INTRODUCTION: Improving muscle strength and maintaining physical function is important for being independence in later life. Short bout 'snacking' exercise is designed to overcome typical barriers to older adults' participation in muscle strength and balance exercise and is acceptable and effective. Moreover, Tai-chi being performed with slow and gentle movements and mental concentration can improve balance and lower extremity strength as well as decrease fear of falling in older adults. To our knowledge, no prospective research has investigated the effects of exercise snacking, Tai-chi, and traditional resistance training on acute muscle activation.

METHODS: This study recruited 18 individuals aged 65 to 80 years who did not regularly engage in recreational sports or structured exercise. Individuals with any chronic illness, contraindications to exercise, or who scored less than 8 on the Short Physical Performance Battery were excluded. Participants were given a demonstration on how to safely perform

exercise snacking and Tai-chi activities at home and asked to do and log 3-days of each activity after two familiarised sessions. In the final session, participants performed exercise snacking, Tai-chi, supplementary unloaded exercises, traditional resistance exercises, and 5-minute treadmill walk in a randomised order. Muscle activation was recorded in the calf, quadriceps, and hamstring muscle groups, using Delsys EMG electrodes. The sample t-test was employed to identify differences in muscle activation variables between exercise snacking/ Tai-chi in comparison to traditional leg press exercise. Statistical significance was accepted at $p<.05$.

RESULTS: Eighteen healthy older adults aged 65 to 80 were recruited for this study. In this study, we found that participants' physical activity levels were slightly higher in the intervention week compared to their regular activity levels. In terms of the EMG integrated activity, the vastus lateralis had greater activities in sit-to-stand compared to leg press. The EMG integrated activity of the gastrocnemius was significantly greater in three of five exercise snacking movements compared to leg press. The EMG integrated activity of the soleus was significantly greater in marching, calf raise, and snake creeps than leg press. The EMG integrated activity of the vastus medialis oblique was significantly lower in four of five Tai-chi movements than leg press.

CONCLUSION: Specific exercise snacking movements could trigger more motor units than traditional leg press exercise. However, it seemed that muscle activated less in Tai-chi movements on thigh muscles. Presumably, motor unit recruitment highly depends on the specificity of training. It is necessary to investigate the effects of long-term exercise snacking and Tai-chi on physical functions.

FEMALE WORLD CHAMPION POWERLIFTING AT 71: THE BENEFITS OF EXERCISE AT AN OLDER AGE

FUCHS, C.J., TROMMELEN, J., WEIJZEN, M.E.G., SMEETS, J.S.J., VAN KRANENBURG, J., VERDIJK, L.B., VAN LOON, L.J.C.
MAASTRICHT UNIVERSITY

INTRODUCTION: Demographics indicate that aging is associated with a progressive decline in skeletal muscle mass, strength, and metabolic health. However, these observations are based on population data and certainly do not apply to the individual. Here, we assessed body composition, muscle strength, cardiorespiratory fitness, and metabolic health of a female world champion powerlifter at 71 years of age, who started resistance exercise training at 63 years of age with no prior experience with structured resistance exercise training.

METHODS: Body composition (Magnetic Resonance Imaging, Computed Tomography, Dual-energy X-ray absorptiometry), strength (One repetition maximum leg press and handgrip strength), cardiorespiratory fitness (peak oxygen consumption: VO2peak), and metabolic health (oral glucose tolerance test, blood pressure) were assessed. In addition, a muscle biopsy was collected to assess muscle fiber cross sectional area (CSA). Where possible, data were compared with sex- and age-matched data obtained in our laboratory. Skeletal muscle mass index was calculated by dividing limb muscle mass by height squared. Data from the control groups are expressed as mean ± 95% confidence interval.

RESULTS: Our participant reported a 33% greater skeletal muscle mass index when compared to healthy, older female control subjects (7.9 vs 5.9 (5.7 to 6.2) kg/m2; n=61). In addition, we observed 37% greater muscle quadriceps CSA (63.8 vs 46.6 (44.5 to 48.7) cm2; n=48) and 46% greater type II muscle fiber CSA (4536 vs 3097 (2707 to 3488) µm2; n=19). Absolute leg press muscle strength was 36% greater (190 vs 140 (132 to 147) kg; n=30) and handgrip strength was 33% greater (33 vs 25 (23 to 26) kg; n=48) when compared to healthy, age-matched controls.

CONCLUSION: From this case study it is evident that even at an older age, improvements in body composition and strength can be achieved by regular exercise training up to the level of a world champion.

DOES MINIMUM AMOUNT OF MODERATE-VIGOROUS PHYSICAL ACTIVITY MATTER FOR MUSCLE STRENGTH AND STATIC BALANCE IN OLDER ADULTS? A 12-MONTH PROSPECTIVE COHORT STUDY

HSUEH, M.C.
UNIVERSITY OF TAIPEI

INTRODUCTION: Whether a minimum amount of moderate-vigorous physical activity (MVPA) is beneficial for maintaining and improving physical function in older adults is unclear. Therefore, this study examined the association between daily 15-minute MVPA and subsequent muscle strength and static balance in older adults.

METHODS: Data on community-dwelling older Taiwanese adults (mean age: 69.5 years ± 4.88) were collected during the baseline period (2018) and through a 12-month follow-up survey (2019). Time spent for MVPA was objectively assessed using a triaxial accelerometer (Actigraph wGT3x-BT) during baseline. Upper and lower limb muscle strength was measured through handgrip strength and 5-times sit-to-stand test (STS), respectively. One-leg standing test was performed to record the static balance performance. The 12-month variations in muscle strength and static balance were calculated by subtracting the follow-up data from the baseline data (categorized as maintenance/improvement and decline). Forced entry adjusted logistic regression was conducted to examine the association between achieving daily 15-minute MVPA in the baseline period and subsequent muscle strength and static balance.

RESULTS: In total, 65.2% of participants engaged in at least 15-minute MVPA per day at baseline. After adjusted potential confounders, older adults who achieved daily 15-minute MVPA during the baseline period were more likely to maintain or improve static balance performance (odds ratio [OR], 95% confidence interval [CI] = 8.12 [1.61-40.97], p = 0.01). For muscle strength, the unadjusted model found that older adults who meet the daily 15-minute MVPA had a significant relationship with STS performance (OR [95% CI] = 4.644 [1.80-11.96], p = 0.001).

CONCLUSION: This study observed that 15-minute MVPA per day might be beneficial for older adults' subsequent performance of balance and lower limb strength. Our findings could be applied for developing future strategies of health promotion, to maintain and improve the static balance and lower limb strength in older adults.

EFFICACY OF A MULTICOMPONENT EXERCISE PROGRAM TO PROMOTE MOTOR AND COGNITIVE RESOURCES FOR NURSING HOME RESIDENTS AS A FUNCTION OF THE RESIDENTS MOBILITY STATUS

CORDES, T., BELOW, T.

UNIVERSITY OF VECHTA

INTRODUCTION: Nursing home residents are often characterized by heterogeneity in motor and cognitive performance with different mobility restrictions. Additionally, it is clearly stated that without exercise, motor and cognitive performance in nursing home residents decreases over time. Multicomponent exercise interventions may enable older people with different mobility status to promote or maintain motor and cognitive resources. However, most interventional studies investigated ambulatory older adults. Less is known about the efficacy of chair-based multicomponent exercise programs for those who are unable to walk. A higher level of mobility might have an influence on the effectiveness of a multicomponent exercise intervention to improve motor and cognitive resources. The aim of this study was to examine the efficacy of a multicomponent exercise program to promote motor and cognitive resources for nursing home residents as a function of the residents mobility status.

METHODS: A quasi-experimental study integrated N=55 nursing home residents (78,90 ± 15,56 years, n=41 female n=14 male, 74.5% female) assigned either to an ambulatory training group (n=20), a wheelchair training group (n=16) or a control group without exercise (n=19). Training duration was 16 weeks for both groups (twice a week; 60 minutes). Type of training was either a multicomponent exercise program for ambulatory residents or a wheelchair-based multicomponent exercise program for residents who are unable to walk. Primary outcomes to assess motor and cognitive resources were independence with the Barthel index, hand grip strength, cognitive status (MoCA), and depressive symptoms (CES-D). Statistics was performed using ANOVA for repeated measures.

RESULTS: The ANOVA revealed no interaction effect between the ambulatory group and the wheelchair group over time. Motor and cognitive resources of both groups remained stable while the control group decreased in all parameters from pre to post ($p < .001$). However, there was a significant time x group interaction between the training groups and the control group for Barthel index ($F(1, 52) = 24,515$, $p < .001$, $\eta_p^2 = .320$), hand grip strength ($F(1, 52) = 68.082$, $p < .001$, $\eta_p^2 = .567$), MoCa ($F(1, 51) = 51.320$, $p < .001$, $\eta_p^2 = .502$) and CES-D ($F(1, 53) = 16.540$, $p < .001$, $\eta_p^2 = .238$).

CONCLUSION: The multicomponent exercise program is beneficial to maintain motor and cognitive resources for nursing home residents regardless of the residents' mobility status, in contrast to a control group with no exercise. The results showed that both, exercise for ambulatory residents and exercise in a wheelchair for those who are unable to walk, can reduce the natural decline of motor and cognitive resources. A higher level of mobility has no influence on the effectiveness of an exercise program for nursing home residents. However, the absence of exercise leads to a decrease in motor and cognitive performance.

HEART RATE AND OXYGEN UPTAKE RESPONSES IN PRE-FRAIL SENIORS USING A PASSIVE-ASSISTIVE HIP EXOSKELETON

PIRSCOVEANU, C., FRANCH, J., HANSEN, E.A., MADELEINE, P.

*AALBORG UNIVERSITY AND *UNIVERSITY COLLEGE ABSALON*

INTRODUCTION: Maintaining walking abilities has been suggested to preserve the quality of life, independence, and social interaction within the senior population (1). Passive-assistive walking exoskeletons are designed to store and release energy during movement and provide walking aid (2). Passive ankle exoskeletons have been shown to reduce by 7.2 ± 2.6% the cardiopulmonary demands during walking (3). Thus, the purpose of this study was to assess a passive-assistive hip exoskeleton influence on heart rate, oxygen uptake, and respiratory exchange ratio (RER) during treadmill walking.

METHODS: Twenty-three pre-frail seniors (72.7±4.6 years, 1.6±0.1 m, 73.1±13.7 kg) walked at their preferred speed (1.9±0.6 m/s) on a motor-driven treadmill (Woodway Pro XL; Woodway Inc., Waukesha, WI, USA) with an exoskeleton (C1), without (C2) and with a sham version (C3). Recordings were made in a balanced order. A bilateral passive-assistive exoskeleton (aLQ) was used (IMASEN, Aichi, Japan). A 7-min walk test was performed in each condition with a 5-min warm-up and 2-min data collection. Heart rate was recorded using a chest strap (Polar RCX5 GPS system, Kempele, Finland). Pulmonary O2 and CO2 were measured by an automated on-line breath-by-breath system (Vyntus CPX, Vyaire Medical, Mettawa, IL, USA). Oxygen uptake and RER were extracted. Paired t-tests were performed for C1 vs C2, C1 vs C3, and C2 vs C3. A p-value of .05 or less was considered significant.

RESULTS: No significant differences in heart rate were observed between the three walking conditions (C1: 100.0±17.0 bpm; C2: 102.3±17.6 bpm; C3: 99.7±17.3 bpm), with $p = .18$ for C1 vs C2, $p = .67$ for C1 vs C3, and $p = .11$ for C2 vs C3. Similar results were found for oxygen uptake showing only a 2.5% difference between C1 (771.8±195.4 ml/min) and C2 (791.3±207.6 ml/min, $p = .14$), around 1.3% difference between C1 and C3 (781.9±188.6 ml/min, $p = .28$) and 1.2% difference between C2 vs C3 ($p = .47$). Similarly, no significant differences were found for the RER between the exoskeleton conditions (C1: 0.85±0.03; C2: 0.85±0.03; C3: 0.85±0.03), with $p = .67$ for C1 vs C2, $p = .36$; C1 vs C3, and $p = .19$ and C2 vs C3.

CONCLUSION: Walking at the preferred speed with aLQ or its sham version did not influence heart rate and oxygen uptake of pre-frail seniors, although the device does add a weight of approx. 1kg to the person wearing it. Unaffected RER

values also suggest that the relative contribution of fat and carbohydrate oxidation is maintained during walking. Therefore, this device could potentially be worn by other more at-risk populations without adverse effects from this perspective.

TRAINING IMPULSE (TRIMP) EVALUATION IN OLDER AMATEUR CYCLISTS: EFFECTS OF HEALTH STATUS

NEWTON, E., SIEGEL, L., MILBOURN, E., FATHI, A., FRANCIS, T., DUGGAL, N., LORD, J., LAZARUS, N., POLLOCK, R., HARRIDGE, S.

KINGS COLLEGE LONDON

INTRODUCTION: Ageing is typically associated with a decline in aerobic power, even in exercisers[1]. In addition, disease status can impact this rate of decline both directly and through altering exercise and physical activity levels.

The aim of the present study was to investigate the effects of diseases of various aetiologies on the training characteristics of amateur road cyclists.

METHODS: Fifty-three older amateur road cyclists were categorised into three groups based on either i) no declared health issues (Group 1, 14=M (males), 8=F (females)), ii) exhibiting new but well-controlled health condition(s) unlikely to affect exercise (Group 2, 13=M, 6=F) or iii) having any other underlying condition(s) that may compromise the ability to exercise (Group 3, 8=M, 4=F). Two self-selected rides on the road (100km for males, 60km for females) were tracked using a Garmin watch and heart rate sensor. Cycling intensity was quantified as training impulse (TRIMP) using the methods of Banister[2] and Edwards[3]. Percentage of time spent in 5 pre-determined HR zones was also determined (Zone 1=50-59%, Zone 2=60-69%, Zone 3=70-79%, Zone 4=80-89%, Zone 5=90-100% of maximum HR). Self-reported cycling volume was collected and actigraphy was performed over a 7-day period. Maximum heart rate (MHR) and maximal aerobic power (VO2max) were determined from an incremental exercise test. Depending on normality, One-Way ANOVA or Kruskal-Wallis H-test were used to compare health groups. Data are presented as mean±SD.

RESULTS: Results are presented in order of Group 1 to Group 3. There was no significant difference ($p>0.05$) in age (71.5±1.2, 71.6±1.3, 70.9±.1.8 yrs), VO2max (39.4±1.0, 35.4±2.7, 35.4±1.9 ml/kg/min), MHR (159.9±3.3, 156.0±4.4, 154.6±3.8 bpm), self-reported cycling volume (480±72, 576±83, 514±88 km/month), average velocity (18.3±1.0, 17.5±1.0, 17.2±0.9 kph) or total ascent (597.6±48.6, 621.9±67.1, 561.8±84.5 m) between groups.

There was no significant difference in Edward's TRIMP (260.8±13.7, 260.6±18.6, 266.0±18.0), Bannister's TRIMP (315.9±26.0, 399.1±58.3, 325.0±32.5) or time spent in zones 1,2,3,4 and 5 between groups. Actigraphy also revealed no differences in time spent in any activity zone.

CONCLUSION: Counterintuitively, these data show that in older amateur road cyclists their training characteristics need not be adversely affected by the presence of some diseases.

RELATIONSHIP BETWEEN EXERCISE TYPE, FREQUENCY AND COGNITIVE FUNCTION IN COMMUNITY DWELLING ELDERLY

YOON, J., HASHIMOTO, H., NISHIMURA, I., SHIBUYA, K., OKURA, T.

UNIVERSITY OF TSUKUBA

INTRODUCTION: Exercise has been suggested to prevent age-related cognitive decline and neurodegenerative diseases, and the usefulness of exercise interventions for cognitive decline in the elderly is also recommended. However, the effects may vary depending on the type and frequency of exercise. In this study, we investigated the relationship between type and frequency of exercise and cognitive function in the elderly.

METHODS: The subjects of this study were 273 elderly residents of Kasama city (74.4 ± 5.0, aged 65-93 years). They were divided into three groups: ① a non-exercise (NEX) group, ② an exercise (EX) group, which consisted of those who practiced regular exercise, and ③ a DEX group, which consisted of those who practiced exercise combining brain training and physical exercise. The ② and ③ groups were further divided into two groups (high- and low-frequency groups), and the results were compared and verified according to the frequency. The Five Cognitive Tests (5-Cog) was used for the cognitive function evaluation in the study. The 5-Cog test is a screening method used in Japan to detect cognitive decline in the elderly. The test material (DVD) consists of performing five elements such as attention, memory, spatial cognitive ability, language ability, and judgment. Amyloid beta (Aβ1-42) in plasma was determined as the secondary outcome.

RESULTS: The total score of the 5-Cog test was not significantly different, but the DEX group scored the highest (NEX group = 82.1 score, EX group = 80.2 score, DEX group = 85.7, p = 0.070).

In addition, the DEX group performed significantly higher on the memory subscale, with the post-hoc test results showing that the DEX (21.8 score) group scored significantly higher than the NEX group (19.1 score) and the EX group (19.2 score) (p = 0.009). On the other hand, the DEX group showed higher, although not significant, concentrations of Aβ1-42 in plasma (NEX group = 4.91 pmol/L, EX group = 5.55 pmol/L, DEX group = 6.07 pmol/L, p = 0.441, higher the better). The results of the analysis by frequency showed no significant differences in any of the items (p = 0.220-0.958)

CONCLUSION: The study showed that older adults who habitually practice DEX showed a tendency to maintain better cognitive function. In particular, memory score was significantly higher than that of other groups. The DEX in this study is an exercise method to remember and replicate the pattern of steps (1). Therefore, it is possible that the memory and replicate operation may have a favorable effect on memory maintenance/improvement. On the other hand, no significant difference for frequency of practice was obtained. Approximately 40% of elderly Japanese do not exercise. The results of this study showed that those who had an exercise habit (1time more than 30 minutes, twice a week, more than one year) maintained good cognitive function. Therefore, it is desirable to practice DEX at least twice a week for more than 30 minutes each time.

EARLY LIFE SPORTS PARTICIPATION AND LATER LIFE HEALTH-RELATED OUTCOMES IN JAPANESE ADULTS OVER 60 YEARS OLD

TOTTORI, N., KOIZUMI, N., FUKAO, N., OKUMURA, K., FUJITA, S.

RITSUMEIKAN UNIVERSITY

INTRODUCTION: Childhood experiences of sports and physical activity are strongly associated with physical activity and health later in life. High levels of physical activity in childhood and adolescence predict high levels of physical activity in adulthood (Telama et al., 2005). Maintaining physical activity from adolescence to young adulthood is associated with a lower risk of cardiovascular disease in later life (Rangul et al., 2012). In addition, recent studies suggest early life physical activity enhances the cognitive functions later in life. However, associations of participation in sports in childhood and adolescence and health-related outcomes such as muscle mass, muscle function, executive function, and quality of life in old age are not well understood. The aim of this study was to investigate the associations between sports participation in childhood and adolescence and the health-related outcomes in Japanese adults aged over 60 years old.

METHODS: One hundred and fifty-four older adults (71.6 ± 6.6 years; male, n = 61; female, n = 93) participated in this study. Experience and weekly frequency of participation in sports during primary school, secondary school, and senior secondary school were obtained by face-to-face interviews. Current total physical activity was assessed using the IPAQ-short form. Body compositions including lean soft tissue mass and fat mass were assessed by dual-energy x-ray absorptiometry. Muscle function was assessed by the Timed Up and Go test and 30-second chair stand test. Executive function was assessed by the Digit Span Forward and Backward tests for working memory, the Stroop test for inhibition, and the Trail Making test for cognitive flexibility. Health-related quality of life was measured by a WHOQOL-26 self-report questionnaire.

RESULTS: Experience of early-life participation in sports was significantly associated with current total physical activity ($P < 0.05$). The participation in sports during primary school was significantly associated with the Timed Up and Go test ($P < 0.05$), while no association between early life sports participation and body composition was observed. The participation in sports during senior secondary school was significantly associated with the results of the Trail Making test in males ($P < 0.01$). The experience of early life sports participation and the frequency of participation in sports during secondary school were significantly associated with the health-related quality of life in females (Ps < 0.05). After adjusted for confounders such as age, education level, and current total physical activity, those results remained.

CONCLUSION: The results of this study revealed that participation in sports in childhood or adolescence positively predicts the muscle function, executive function in males and quality of life in females later in life. These findings suggest that early intervention should promote sports participation in childhood and through adolescence for lifelong physical and psychological health.

MUSCLE DAMAGE MAY BE DETRIMENTAL FOR EXERCISE-INDUCED COGNITIVE IMPROVEMENT IN OLDER MEN: PILOT RESULTS FROM THE BRAIN-M TRIAL

MASIULIS, N.1, VINTS, W.A.J.1, KVEDARAS, M.1, ZIV, G.2, MAMKUS, G.1, CESNAITIENE, V.J.1, LEVIN, O.1, PÄÄSUKE, M.3

1-LITHUANIAN SPORTS UNIVERSITY, LITHUANIA. 2-THE LEVINSKY-WINGATE ACADEMIC CENTER, NETANYA, ISRAEL. 3-INSTITUTE OF SPORT SCIENCES AND PHYSIOTHERAPY, UNIVERSITY OF TARTU, TARTU, ESTONIA.

INTRODUCTION: It is well documented that resistance training can augment muscle function and preserve brain health in older adults. It is also known that high-intensity resistance training can cause muscle damage, associated with low-grade inflammation, which has a negative effect on cognitive function. In this randomized controlled trial we hypothesized that muscle damage (expressed by increased creatine kinase, CK) would be associated with decreased cognitive performance in older adults. To examine this hypothesis we compared two resistance exercise intervention protocols consisting of either a high mechanic (high CK) or a high metabolic (low CK) loading.

METHODS: Twenty-two older men (60-74y old) were randomly allocated to a single session of accentuated eccentric-only resistance training (ECC, n = 6), blood flow restriction training (BFRT, n = 10), or 45-min seated rest (n = 6). Both exercise groups performed three lower body exercises at an equal relative volume of 57.6% (number of exercises x sets x repetitions x % one repetition maximum, 1RM). ECC consisted of 4 sets and 4 repetitions each at 120% 1RM. BFRT consisted of 4x12 repetitions at 40% 1RM and 50% lower limb occlusion pressure. Two-way ANOVA (Group X Time) with repeated measures on the Time factor was used to assess pre-to-post 5-min changes in cognitive function and pre-to-post 48h changes in blood CK (U/L). Cognitive tests included a 2-Choice Reaction Time test, Go/No-Go test, Memory Search test, and a Switching task. The main cognitive outcome measures were response time (RT, ms) of the correct responses, and changes in performance index (PI; 100×[accuracy/response time of all responses]).

RESULTS: A significant Group x Time interaction was found for CK level changes ($p=0.049$, partial $\eta^2 = 0.315$). CK levels significantly increased in the ECC group (+14.14 ±16.63 U/L), but not in the BFRT (+3.21 ±3.21 U/L) and control group (-0.12 ±0.97 U/L). The Group x Time interaction for RT in the Memory Search Test was not significant ($p=0.139$, partial $\eta^2 = 0.218$). Based on the large effect size it appears that RT improved only in the ECC group (-99.72 ms) but not in the BFRT (+64.36 ms) and control (+95.87 ms) groups. However, in the ECC group, improvement in RT on Memory Search test was significantly lower with higher Pre-Post increases in CK ($R = 0.921$, $p = 0.026$). There were no significant changes on other cognitive function tests.

CONCLUSION: A single bout of ECC tended to improve memory function compared to BFRT and control groups. However, muscle damage may have detrimental effects on the magnitude of this improvement. Our findings suggest that resistance training may benefit cognitive function in older adults, however high level of muscle damage should be avoided.

WHY IS HIMT SUCH A HIT? AN ONLINE SURVEY EXPLORING SUBJECTIVE RESPONSES IN HIGH-INTENSITY MULTIMODAL TRAINING.

SHARP, T., GRANDOU, C., COUTTS, A., WALLACE, L.

UNIVERSITY OF TECHNOLOGY SYDNEY FACULTY OF HEALTH

INTRODUCTION: High-Intensity Multimodal Training (HIMT) has recently gained interest as a time-efficient method of promoting physical health. Despite the proposed health and fitness benefits of HIMT, the subjective response to HIMT remains unclear. Previous studies suggest HIMT participation promotes increased exercise enjoyment and intrinsic factors related to adherence. In contrast, other studies have demonstrated feelings of pain and displeasure following similar aerobic-based high-intensity exercise. These conflicting findings limit the understanding of the subjective response to HIMT, in particular exercise enjoyment. The purpose of this study was to investigate exercise enjoyment in HIMT and identify factors associated with HIMT that mediate exercise enjoyment and motivation. This may provide a clearer understanding of subjective responses in HIMT and assist in explaining long-term training behaviours, in particular exercise-adherence.

METHODS: A web-based survey was distributed to a cross-sectional voluntary convenience sample of current HIMT participants and drop outs. The 124-item survey was distributed via email, and social media from August through to the end of September 2021. The final sample included 469 responses (completion rate: 61.6%). Of the total eligible respondents, 379 were current HIMT participants, 55 were drop outs.

RESULTS: The most frequently reported reasons for increased exercise enjoyment and motivation to continue HIMT in current participants included (1) it keeps me fit, (2) training in a group and (3) there is variety in a session. The most frequently reported reasons for reduced motivation to continue HIMT among drop outs included (1) other (injury, COVID-19 restrictions, low motivation, personal preferences), (2) work commitments were a priority and (3) I started another type of sport, exercise or training.

CONCLUSION: The findings of this study indicate that HIMT is an enjoyable training method among current participants. The most commonly reported reasons for increased exercise enjoyment and motivation were associated with the combination of aerobic and resistance training as well as the group environment. In contrast, reasons for reduced motivation to continue HIMT among drop outs were associated with commonly reported barriers to exercise and personal factors or interests. These findings identify some of the factors that may underlie subjective responses in HIMT. This may assist in better understanding the growing popularity of the training mode and guide tailored service delivery in the community for increased exercise adherence.

EFFECT OF LOW-INTENSITY EXERCISES ON CIRCULATING ENDOCANNABINOID LEVELS AND ITS IMPACT ON PSYCHOLOGICAL STRESS REDUCTION: A RANDOMIZED AND COUNTERBALANCED CROSSOVER STUDY

YABE, T., ANDO, D., KOYAMA, K.

YAMANASHI GAKUIN UNIVERSITY

INTRODUCTION: Exercise has the decreasing effect of psychological stress and there is a growing attention on blood endocannabinoids (eCB) as one of the candidate molecules that cause the effect. However, no optimal exercise program (i.e., intensity, duration) in consideration of the level of eCB to reduce psychological stress has been established. Hence, this study investigated the changes in blood eCB levels before, during and after low-intensity exercises and examine whether the eCB reduces psychological stress and is appropriate for a biomarker of affective improvement.

METHODS: Fifteen healthy male college students were participated in a randomized and counterbalanced crossover trial that consists of two different low-intensity exercises at intensities corresponding to 30% and 50% of heart rate (HR) reserve. They performed 60-min cycle exercises at the same time (13:00–17:00 h) to avoid the effect of a circadian rhythm under the two conditions separated with a one-week washout interval. At rest, 10 min and 30 min during exercise and immediately after exercise, blood samples were collected and plasma N-arachidonoylethanolamine (AEA) and 2-arachidonylglycerol (2-AG) concentrations were measured. The participants responded to the survey of the physical activity affect scale (PAAS) as an affective index including four subscales, positive affect, negative affect, tranquility, and fatigue before and immediately after the exercise. Statistical significance was set at $p < 0.05$.

RESULTS: The two-way repeated measures ANOVA regarding plasma AEA and 2-AG concentrations showed that no significant interaction between exercise intensity and time, and no main effects of exercise intensity and time were found. Exercise had no significant impact on "positive effect". However, main effects of time were observed in both "negative affect" ($p = 0.05$) and "tranquility" ($p < 0.00$). Although a significant interaction was found in "fatigue" ($p = 0.02$), multiple comparison did not reveal any significant differences between individual data. Interestingly in more lower intensity exercise (i.e., 30% HR reserve), there was a significant negative correlation between the changes in plasma AEA levels from rest to 10 min after beginning of the exercise and in "negative affect" scores from rest to immediately after exercise ($r = -0.64$, $p = 0.04$).

CONCLUSION: There was no significant variation in plasma AEA and 2-AG concentrations during and after low-intensity exercises. However, we found that low-intensity exercise decreased "negative affect" likely caused by psychological stress. In addition, since the increase in plasma eCB concentration relates to the decrease in "negative affect", eCB might be useful as one of the biomarkers of low-intensity exercise-induced affective improvement.

DEVELOPMENT OF BEDTIME STRETCHING PROGRAM ENHANCING MOOD AND COGNITIVE FUNCTION

SUWABE, K.1,2, HYODO, K.3, OTSUKI, T.1

1RYUTSUKEIZAI UNIVERSITY , 2UNIVERSITY OF TSUKUBA , 3PHYSICAL FITNESS RESEARCH INSTITUTE

INTRODUCTION: University students are at risk to experience a decline in their mental health (mood and cognitive function) due to lifestyle changes that often include poor sleep hygiene. To resolve this, practicing simple stretching exercise before falling asleep, might be helpful. Previous studies have demonstrated that bedtime stretching improves sleep and mental health [1,2]. Better sleep quality also positively affects cognition: more deep sleep that presents with slow-wave oscillations can enhance executive function and memory performance [3,4]. Therefore, a bedtime stretching program could have a positive impact on mood and cognitive function through improved sleep quality.

METHODS: Twelve male university students participated and ten of them completed all experimental procedures (21.6±1.0 yr) and reported an average Pittsburgh Sleep Quality Index (PSQI) score of 5.3±2.1. In a within-group crossover design, participants either stretched or rested for ten minutes before bedtime; each participant completed both experimental conditions (stretching/resting control) in randomized order and at least two weeks apart, and sleep electroencephalogram and subjective sleep quality were recorded for five days. On the sixth day, participants visited the experimental room and performed the Stroop task and mnemonic discrimination tasks (to assess executive function and memory respectively) completed the Profile of Mood State questionnaire (POMS).

RESULTS: Although paired t-test revealed no significant differences by condition for all parameters, stretching positively influenced sleep and cognition. The effect sizes were large for sleep latency ($d = 0.93$, $p = 0.07$) and Stroop interference time ($d = 0.85$, $p = 0.08$); medium for subjective sleep quality ($d = 0.60$, $p = 0.09$) and the lure discrimination index (LDI) for medium-similarity lures ($d = 0.67$, $p = 0.09$); small for the appearance ratio of stage N3 (deep slow-wave) sleep ($d = 0.25$, $p = 0.40$). In addition, differences by condition in the appearance ratio of stage N3 sleep were positively correlated with differences by condition in Stroop interference times ($r = 0.52$) and LDI for low-similarity lures ($r = 0.54$).

CONCLUSION: Performing ten minutes of a bedtime stretching program positively influenced sleep latency, subjective sleep quality and a deep slow-wave sleep. While five days of the stretching intervention had no effects on mood, they did yield positive effects on executive and memory performance. In addition, these cognitive benefits are related to increased deep slow-wave sleep. Although the sample size of this study was not large enough to provide sufficient statistical power, these results support our hypothesis that a bedtime stretching program has a positive impact on cognitive function through improved sleep quality.

AGE-VARYING EFFECT BETWEEN DOMAIN-SPECIFIC PHYSICAL ACTIVITY AND STRESS PERCEIVED: THE KOREA NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY (KNHANES)

LEE, S.M., MA, X., KIM, Y.S.

SEOUL NATIONAL UNINVERSITY

INTRODUCTION: We examined the association of stress perceived according to physical activity(PA) by age-varying in Korean. Physical function decreases as aging lead to a lack of PA, which eventually negatively impacts mental health(i.e., stress). However, the effect of physical PA technology and industry, many people are re-employed in their old age, and resuming economic activities has a positive impact on PA and mental health. Therefore, it is necessary to confirm the effect of domain-specific PA (i.e., work, leisure time, transfer) and mental health according to the lifespan. The age-varying effect model can help develop more age-targeted and effective interventions for improving mental health through PA.

METHODS: This study used the Korean National Health and Nutrition Survey (KNHANES), and a total of 31,051 participants included those aged 20-80. All data were obtained through self-report questionnaires. Amount PA was calculated for moderate-various work, leisure, and transport related PA from the Global Physical Activity Questionnaire (GPAQ, and common stress perceived level from the mental healthy questionnaire part. Association between PA and stress perceived level was examined by time-varying effect models (TVEM). All statistical analyzes were adjusted for covariates (e.x., gender, education level, occupation, income level, marital status, alcohol assumption, smoking, BMI, and chronic diseases). All data cleaning and analysis were performed using the R and SAS program.

RESULTS: Those who participate in work-related moderate to vigorous intensity PA show a pattern of gradual stress reduction with age-varying. In addition, stress perceived level was also founded to be reduced in the context of leisurely moderate to vigorous PA and transport PA. Moreover, compared with those who did not meet WHO PA guidelines(≥150min/week), those who did show a pattern of rapid decrease in stress with age. The association peaked at around age 30-45(95% CI:1.1, 1.45; 95% CI:0.75, 0.95).

CONCLUSION: The association of PA and common stress perceived level was confirmed according to the time(age)-varying effect model. The significant associations of domain-specific PA and stress level across age groups. As a result, a commonly perceived stress level negatively impacts mental health in previous studies. PA is essential in all lifespans, and it has been reported that work-related PA has an inverse association with stress, but this study showed that all types of PA positively affect mental health.

THE EFFECT OF PROLONGED AEROBIC EXERCISE AT MODERATE INTENSITY ON CARDIAC DIASTOLIC FUNCTION

HATA, N., FUKUIE, M., SUZUKI, R., HIRABUKI, K., UECHI, T., HIRASAWA, A., MATSUDA, T., SHIBATA, S.

KYORIN UNIVERSITY

INTRODUCTION: It is generally known that regular exercise training has beneficial effects on human health, especially on the cardiovascular system. However, some previous studies showed that long-duration exercise might acutely impair heart function. These findings are often based on fieldwork studies, in which it is not practical to evaluate cardiac function during exercise. Therefore, time course changes in cardiac diastolic function during prolonged exercise are still unclear. This study aimed to observe the cardiac diastolic function during and after a moderate-intensity bicycle exercise for 3 hours. We hypothesized that diastolic function would be impaired as exercise duration increases and that it would not be recovered after exercise.

METHODS: Nine healthy adult male subjects (36 ± 6 years) participated in the study. Subjects were required to attend the laboratory with conditions set to 20-22◦C and 50-70% humidity on two occasions separated by a minimum of 1 week. On the first day, subjects completed incremental exercise tests according to guidelines by the American College of Sports Medicine in order to assess maximal oxygen consumption (VO2 max). On the second day, subjects performed bicycle exercises at the intensity of 60-70% VO2 max for 3 hours on a pedal-equipped echocardiography bed. Echocardiographic measurements were performed before exercise (PRE), every 30 minutes (30, 60, 90, 120, 150, and 180 minutes) during exercise, and 15 minutes after exercise (POST). We measured heart rate (HR), mitral annulus blood flow and tissue motion velocities in early (E or e) and late (A or a) diastole, and isovolumic relaxation time (IVRT).

RESULTS: The subject's average VO2 max was 43.7±8.8 mL/kg/min (±SD). HR was higher during exercise as compared with PRE, and gradually increased during exercise, which reached statistical significance after 90 minutes as compared with 30 minutes. HR was higher at POST than at PRE. E/A was lower during exercise as compared with PRE, which did not change during exercise. E/A was lower at POST than at PRE. e' was higher during exercise as compared with PRE, which did not change during exercise. e' did not differ between PRE and POST. E/e did not change either during or after exercise. IVRT was shorter during exercise as compared with PRE, but gradually prolonged during exercise, which reached statistical significance after 120 minutes as compared with 30 minutes. IVRT was longer at POST than at PRE.

CONCLUSION: The present results that IVRT became shorter just after the exercise began, but prolonged as the moderate intensity exercise continued indicated that LV diastolic function was acutely enhanced by exercise itself, but impaired due to the long duration of exercise. However, the present results that e' did not change during and after exercise may indi-

cate that diastolic function was not affected by the long duration of exercise. Since IVRT reflect the early phase of diastolic relaxation, while e' reflec

SPORT-SPECIFIC-ORIENTED ADAPTATION IS REVEALED BY MICROBIOME CHARACTERISTICS.

HUMINSKA-LISOWSKA, K., ZIELINSKA, K., MIESZKOWSKI, J., MICHALOWSKA-SAWCZYN, M., CIESZCZYK, P., LABAJ, P., KOCHANOWICZ, A., KOSCIOLEK, T.

GDANSK UNIVERSITY OF PHYSICAL EDUCATION AND SPORT

INTRODUCTION: The gut microbiome is a live community of interacting components including bacteria, implicated in human health and disease. Studies comparing sedentary individuals to athletes have identified numerous characteristics of a healthy microbiome, and features correlated with athletic performance. However, the range of work on the intestinal composition among groups divided by physical exercise levels is limited. Therefore our study aimed to compare basic differences in the microbiome of trained and non-trained physically active men as well as to assess post-exercise microbiome response dependent on the sport specification to identify microbiome characteristics.

METHODS: The participants comprised 15 strength-oriented, 15 endurance-oriented athletes, and 12 physically active male participants as a control group. All completed Wingate Anaerobic Test followed by Bruce (aerobic) Test. Basic anthropometric characteristics (age, height, weight) and test results (average and max power during Wingate Test, VO2max during Bruce Test) were gathered for each participant. Stool samples were collected immediately before and twice after the testing (3 time-points per intervention). Taxonomic and functional profiles were obtained from sequenced samples using Metaphlan4 and Humann3.6 and further analyses were conducted using Qiime2 and custom python scripts.

RESULTS: Comparison of Control, Strength, and Endurance groups revealed no significant differences in microbiome richness. However, 34% of identified bacterial species and 7% of functions were unique to either of the groups. The longitudinal analysis detected Alistipes_communis as significantly enriched in the Strength group during Wingate Test, and diverse individual trends in abundance of 88 species during Bruce Test. Those included short-chain fatty acids producers with probiotic properties (Bacteroides_xylanisolvens, Ruminococcus_bromii, Roseburia_hominis). The individuals were also compared based on their biomechanical and physiological results. A machine learning approach identified Bifidobacterium_longum (a probiotic tested on athletes) as the main predictor of VO2max and average power at baseline. Species longitudinally enriched in high versus low average power group (high >= 8.5, low <= 8W/kg) during Wingate Test included Bacteroides_uniformis and Phocaeicola_dorei. Similarly, Phocaeicola_vulgatus and Bacteroides_thetaiotaomicron were more abundant in high versus low VO2max groups (high >= 62, low <= 55 mL/kg/min) during Bruce Test. Also, a greater microbiome richness was observed in the high versus low VO2max group.

CONCLUSION: The study identified microbiome characteristics previously known to be implicated in elite-level performance and revealed differences between strength- and endurance-oriented athletes and non-trained physically active men. Ultimately, the results in this area carry a great potential to develop strategies for microbiome alteration to optimize human performance.

PHYSICAL ACTIVITY LEVELS AND SLEEP QUALITY IN AFRICAN AND ASIAN STUDENTS DIFFER FROM EUROPEANS AND AMERICANS. A GLOBAL SURVEY ON 3366 STUDENTS FROM 49 COUNTRIES

MOUSSA-CHAMARI, I.

QATAR UNIVERSITY

INTRODUCTION: Poor sleep and low physical activity (PA) levels has become a major scourge among university students worldwide [1], with sleep issues becoming a common problem in this population [2]. We assessed subjective reports of sleep quality (SQ) and PA in university students globally.

METHODS: We surveyed 3366 students (aged 22.7±5.5 years) from 49 countries, continentally located in: Africa (n=1095); Asia (n=1562); America (n=182); and Europe (n=527); and regionally from: North Africa (N=571); Sub-Saharan Africa (n=521); Southeast Asia (n=186); Middle-east-GCC (Gulf Cooperation Council) (n=498); Non-GCC Middle-East (n=898); North America (n=157); South America (n=25); and Europe (n=526). Our online survey included four questionnaires validated in three languages (Arabic, English & French): (i) Pittsburgh Sleep-Quality Index (PSQI), (ii) Epworth sleepiness-scale (ESS), (iii) Insomnia severity index (ISI) and (iv) International PA Questionnaire (IPAQ) assessing SQ, daytime sleepiness, insomnia and PA, respectively.

RESULTS: SQ of the African and Asian students was significantly lower than that of Americans and Europeans (mean±SD of PSQI scores: 6.4±2.8; 6.5±2.8; and 5.7±2.7; 5.5±2.4; respectively, $p<0.001$). The sleepiness and insomnia of African and Asian students were significantly higher compared to Americans and Europeans (ESS scores: 9.4±4.6; 10.0±4.7; 8.0±4.1; 7.5±3.9; ISI scores: 9.6±6.0; 10.0±5.8; 8.3±5.4; 7.5±5.3, respectively $p<0.001$). Africans and Asians were less physically active than Americans and Europeans. The SQ and PA were significantly lower for students from, Middle East (GCC and non GCC), North- and Sub-Saharan-Africa and South East-Asia compared to Europeans ($p<0.05$ to $p<0.001$). Students from Middle East and North Africa had higher sleepiness compared to those from other sub-regions ($p<0.001$). The global insomnia scores of this sample of international students were higher than the normal but with significantly higher values for students from Middle-East and North-Africa compared to Europe, North America and sub-Saharan-Africa ($p<0.001$).

CONCLUSION: We showed that students from Africa and Asia have poorer SQ and lower PA levels than Americans and Europeans. More investigation into sub-regional specificities would identify the associated causes. As the importance of SQ and PA in supporting physical and psychological health, these topics should be considered with particular attention in students from Asia and Africa.

EFFECT OF DIFFERENCE IN TIMING OF EXERCISE ON HUMAN CIRCADIAN CLOCK GENE EXPRESSION

E.TSUDA, R.MICHISHITA, M.SAKAMOTO, S.KAWAKAMI, T.ABE, S.NAKASHIMA, Y.HIGAKI, Y.UEHARA

FACULTY OF SPORTS AND HEALTH SCIENCES, FUKUOKA UNIVERSITY

INTRODUCTION: It is well known that circadian rhythm disorders progress to development of various disease such as diabetes, cancer, depression, and sleep disorders. The circadian rhythm is thought to have been regulate to the light stimulation, diet, exercise, thermoregulation, and hormonal balance. From the perspective of disease prevention, it is extremely important to consider the effects of lifestyle modification on the progress of the circadian rhythm. It has been reported that circadian rhythm is controlled the clock gene, and a few animal studies shown a single bout of exercise is effective in advancing clock gene expression. However, the effect of difference in timing of exercise on circadian clock gene expression had not been clarified. This study was designed to examine the effects of difference in timing of exercise on human circadian clock gene expression.

METHODS: Five healthy young males (age, 23.8 ± 1.9 years; BMI, 23.1 ± 3.1kg/m2) participated in a two-night, three-day residential study. This study set the following four conditions of timing of exercise; 1) morning exercise (exercise starts at 8:00 am), 2) daytime exercise (exercise starts at 12:00 pm), 3) night exercise (exercise starts at 5:00 pm), and 4) control (no exercise). All of participants were performed to exercise using a bicycle ergometer for 60 min at the lactate threshold (LT) intensity. The hair of head was collected a total of 6 times every 4 hours starting at 7:00 am on the test day, and the expression levels of Clock, Bmal1, and Per2 mRNAs were analyzed from the hair follicle cells using real-time PCR method. Salivary sample was collected from 20:00 to 23:00 on every 30 min the test day, and from 6:00 to 8:00 on every 30 min the next morning to measure the salivary melatonin, serotonin and cortisol secretion. This study was examined the difference in relative expression levels of clock gene, and changes in salivary melatonin, serotonin and cortisol secretion levels among the above four conditions.

RESULTS: The mean LT intensity and maximal oxygen uptake in all of participants were 95.8 ± 13.9 watts, and 47.5 ± 6.5 ml/min/kg, respectively. The relative expression level of Bmal1 mRNA increased after exercise in the morning and daytime exercise conditions. However, there was no difference in the relative expression levels of Clock and Per2 mRNA among the four conditions. Although there was no difference in the change in salivary melatonin secretion level among four conditions, DLMO (Dim Light Melatonin Onset) was the fastest in the morning exercise condition compared to the other three conditions. However, there was no difference in the changes in salivary serotonin and cortisol secretion levels among the above four conditions.

CONCLUSION: These results suggested that morning and daytime exercise may increase the expression level of circadian clock gene, particularly Bmal1 mRNA, and morning exercise may promote melatonin secretion level.

POTENTIAL FOR LONG-TERM HEALTH DAMAGE IN MULTI-MARATHONERS – AN OBSERVATIONAL STUDY

LUNDY, L., REILLY, R.B., FLEMING, N.

TRINITY COLLEGE DUBLIN

INTRODUCTION: Introduction: The sport of multi-marathoning, where participants frequently complete marathon distance with a goal of completing >100 marathons, is not well researched. This study documented the sport and examined the participants readiness to participate in vigorous activity and their potential for long-term health damage. Multi-marathoning is administered at a national level by 31 loosely connected 100 marathon clubs. These virtual clubs provide registration, community, events, motivation, and awards to their members. Several clubs do the same internationally. There are 961 athletes on the current multi-marathoning world rankings (>300 marathons), and 10k are documented by the clubs as having achieved >100 marathons. There are many more on the journey to this goal.

METHODS: Methods: Health awareness and the readiness to partake in vigorous physical activity was examined by using the globally accepted Physical Activity Readiness Questionnaire PARQ+ [1]. Given the geographic spread of participants and the virtual nature of their clubs, an online survey was the most practical way to gather data from this group. This survey was developed and hosted on the Qualtrics platform and was distributed with the help and support of all the major multi-marathon clubs, including 100 marathon clubs from Germany, UK, The Americas, Japan, Finland, Italy, Estonia, Ireland, Australia and New Zealand via their closed Facebook or email groups. The survey was anonymous, presented in English and optimised for mobile devices. Section 1 of the PARQ+ questionnaire on General Health was embedded in the survey.

RESULTS: Results: The survey had 691 respondents from 6 continents and 39 countries. The average number of marathons completed by respondents was 156. 57% of participants had at least one contravention to section 1 of the PARQ+ physical activity readiness questionnaire, while 25% had 2 or more contraventions. 11% had heart conditions, 13% had high blood pressure, 10% had lost balance due to dizziness or had lost consciousness in the previous 12 months, and 34% had bone, joint or soft tissue problems in the previous 12 months that could be made worse by vigorous exercise, 17% had other chronic conditions with 15% taking medication for chronic conditions.

CONCLUSION: Conclusion: Due to the high level of vigorous activity in the sport of multi-marathoning, participants have a high risk of long-term damage to health or succumbing to health-related incidents and should seek further information and/or seek advice from a qualified health or exercise professional before partaking in the sport and have continuous health monitoring [1]. To minimise health risks, multi-marathon clubs and Race Directors should promote awareness campaigns that encourage proper medical assessment based on PARQ+ and ongoing health monitoring by qualified health or exercise professionals.

CAN SELF-SELECTED MOTIVATIONAL MUSIC AFFECT HEART RATE DURING AND POST AEROBIC WORKOUT?

GRIGNANI, L.1, VUKAJ, X.1, SIGNORI, C.1, GALLAZZI, M.1, ANDRIOLO, G.1, FIGINI, A.1, CANTARELLI, D.1, BARATTI, M.1, GHIRARDI, P.1, ANNONI, I.1, BERTOZZI, F.2, GALVANI, C.1, BRUSEGHINI, P.1

1 UNIVERSITÀ CATTOLICA DEL SACRO CUORE; 2 POLITECNICO DI MILANO

INTRODUCTION: Listening to self-selected motivational music (Terry, 2020) during aerobic exercise may induce an excitatory stimulus on physiological parameters (Ballman, 2021), such as the heart rate (HR), in correlation with exercise intensity. However, the effect of music on the recovery phase seems to present an entirely new area of research in the available literature, particularly regarding short-time recovery (Karageorghis, 2012). The purpose of this study was to investigate the influence of self-selected motivational music on HR during recovery.

METHODS: Forty university students (age 22.7±2.6 yrs; BMI 21.8±2.5 kg·m-2; VO2max 39.7±7.9 mLO2·kg-1·min-1) performed different training sessions with (+M) and without (-M) self-selected motivational music. They were divided into three percentile categories (high, average and low) according to their cardiorespiratory fitness level (VO2max), assessed by a submaximal cycling direct test. During each training session, two 6-minute square-wave cycling bouts were performed, interspersed with 10 min of recovery, at two different intensities: 60% of VO2max (Mod) and 90% of VO2max (Vig). Each condition was replicated during two different moments of the day, morning (MO) and evening (EV), for a total of four training sessions. HR was continuously monitored in order to analyse HR peak during exercise (HRpeak), HR at the 1st minute of recovery (HRrec) and the difference between HRpeak and HRrec (ΔHR%).

RESULTS: For the entire group of subjects, no influence of music or time of the day was found. Subjects with high and average VO2max obtained a significantly ($p<0.05$) faster recovery when compared with those with low VO2max, independently of music condition (high VO2max: EV+M 12,4±4,4; EV-M 12,4±4 ΔHR%; average VO2max: EV+M 10,7±3,9; EV-M 10,8±4,2 ΔHR%; low VO2max: EV+M 6,3±2,8; EV-M 5,7±3,4 ΔHR%). At Mod intensity, subjects with high VO2max, independently of the time of the day, obtained significantly greater HRpeak and HRrec values in +M condition compared to -M (HRpeak: MO+M 138.4±11.7; MO-M 136.5±12.6; EV+M 138±8.9; EV-M 134.7±8.3 bpm, p=0.0278; HRrec: MO+M 118.8±11.1; MO-M 119.5±15.5; EV+M 120.2±9.9; EV-M 116.9±8.9 bpm, p=0.0364). In general, listening to motivational music during recovery phase does not affect ΔHR%. No differences emerged for Vig condition.

CONCLUSION: Untrained subjects have a slower recovery phase compared with more trained subjects, and listening to music after the workout doesnt help bridge the gap. Moreover, listening self-selected motivational music, during aerobic exercise and during recovery, in trained subjects, seems to negatively affect recovery capacity, independently of the time of the day.

INTER-ORGANISATIONAL RELATIONSHIPS BETWEEN GOVERNMENTAL STAKEHOLDERS IN SOUTH AFRICAN ELITE SPORT: RESOURCE DEPENDENCY AND INTER- ORGANISATIONAL THEORETICAL PERSPECTIVES

JACOBS, S.1, DE BOSSCHER, V.2, VENTER, R.1

STELLENBOSCH UNIVERSITY (1) AND VRIJE UNIVERSITEIT BRUSSEL (2).

INTRODUCTION: Stakeholder relationships within high-performance sport are critically important for the success and growth of nations elite sporting systems. The characterisation of the varying type of inter-organisational relationships can

directly influence the implementation of the sport policies within practise. Herewith, it is critically important to understand the dynamics these relationships present. If inter-organisational relationships between stakeholders in elite sport are aligned more strategically by nations, then stronger elite sporting systems will be created. The aim of the study was to evaluate the inter-organisational relationships between governmental stakeholders in order to identify the influences it has on the effectiveness of elite sport policies in South Africa (SA). The study contributed to academic scholarship by juxtaposing two theoretical frameworks, namely, the resource dependency (RDT) and inter-organisational (IOR) theoretical perspectives. The case study evaluated the vertical IOR's between national and provincial stakeholders in one province in SA, namely the Western Cape.

METHODS: The IOR partnership was examined with the use of an exploratory qualitative method by means of 10 face-to-face, semi structured interviews on the elements identified in the theoretical perspectives. A purposive sampling method was used including only key informants namely; the national and provincial stakeholders in the elite sport portfolio's, respectively. Data were analysed by means of thematic analysis in order to apply inductive and deductive reasoning in Nvivo (v.12) software.

Results and discussion:

The theoretical contribution of using both the RDT and the IOR theories in this study, jointly assisted in the knowledge pertaining to why governmental IOR partnerships are formed, in what way they are managed, what the outcomes are, and lastly, how financial resources played a role in the dynamics of these relationships. The major findings illustrated that: (1) there is a perceived lack of clarity relating to the roles and responsibilities of governmental sport stakeholders, (2) too many entities are involved in sport which led to power struggles and non-cooperation, and (3) a lack of funding introduced issues of power within IOR's. The current results of this study have confirmed what has been found in the literature which relates to the challenging and often overwhelming influence of IOR management (Alexander et al., 2008). The findings of this study add's to the field of sport management research by illustrating the issues and concerns which obstructed the implementation of elite sport policy in this case study. Similarly, it identified the factors which facilitated the formation, management and outcomes of IOR's between governmental stakeholders. Jones et al. (2017) argued that a lack of collaboration within IOR's may impact upon sport entities ability to deliver consistent services.

AN ANALYSIS OF VALUE SYSTEM OF TAEKWONDO FREESTYLE POOMSAE'S TRAINEES: BASED ON MEANS-END CHAIN THEORY AND APT LADDERING TECHNIQUE

CHOI, Y.L., PARK, J.C., KIM, I.G.

KOREA NATIONAL SPORT UNIVERSITY

Introduction

Today, Taekwondo gyms are experiencing a continuous decrease in the number of trainees, due to the oversupply of the gyms, excessive competition, and the COVID-19 pendemic. To solve the problems, various programmes are needed to satisfy the needs of Taekwondo trainees. Among them, Freestyle Poomsae allows trainees to feel more fun, artistry, and creativity than other Taekwondo events. In this context, it is necessary to study what kind of decision-making process trainees start and continue the Freestyle Poomsae. Therefore, the purpose of this study is to explore the attributes, benefits and values of Freestyle Poomsae perceived by trainees, and then to understand the connection relationship and cognitive process based on a Means-End Chain method proposed by Gutman(1982).

Methods

First, data were collected by in-depth interviewing with 10 Taekwondo-related participants, including trainees, coaches and professionals in 2022 by using judgement sampling. Transcribed data is categorised by grouping similar concepts through open coding. After that, each attribute, functional benefit, psychological benefit and value group was finally derived through member checking and cross-validation among professors and PhD researchers. Second, based on the previous results, data were collected from 317 students learning Freestyle Poomsae through Structural Implication Matrix survey. Lastly, Hierarchical Value Map(HVLM) through frequency analysis is created to identify the connection structure between attributes, benefits and values.

Results

Attributes, functional and psychological benefits, and values of Freestyle Poomsae were derived in 12, 11, 8, and 8, respectively. As a result of analysing the value system based on the above findings, three main value systems were derived. First, Freestyle Poomsae's creativity led to a sense of accomplishment through originality and showing myself to others. Second, expressions of individuality led to a sense of accomplishment through originality, and showing myself to others. Lastly, a event with music led to self-satisfaction and a sense of accomplishment through maximising expressions with actions and music, and a fine piece of work.

Conclusion

It was found that Freestyle Poomsae contained creavity, individuality, and music compared to other Taekwondo events. Taekwondo instructors should help trainees to develop their originality and show themselves with great works, and further they should guide trainees in a way that ultimately feels a sense of accomplishment and self-satisfaction. Thus, Taekwondo gyms are needed to emphasise the main benefits and values mentioned above when establishing a marketing communication strategy, contributing to expanding the base of Freestyle Poomsae and strengthening its competitiveness.

AN INTRODUCTION TO THE INTERNATIONAL CONFEDERATION OF SPORT AND EXERCISE SCIENCE PRACTICE AND THE NEED FOR GLOBAL ADVOCACY

DAVISON, K.

UNIVERSITY OF SOUTH AUSTRALIA

INTRODUCTION: The International Confederation for Sport and Exercise Science Practice (ICSESP) was formed by the American College of Sports Medicine (ACSM), British Association of Sport and Exercise Sciences (BASES), Canadian Society for Exercise Physiology (CSEP), Exercise and Sports Science Australia (ESSA), and Sport and Exercise Science New Zealand (SESNZ) to promote and support the interests of Sport and Exercise Science (SES) practitioners across the world. To support this agenda, the ICSESP undertook a survey of practitioners worldwide to understand the context of their practice and the challenges and opportunities facing them in their roles locally and internationally.

METHODS: The survey was developed by the representative directors of the five organisations who each have extensive national leadership in SES practice and links to international networks. The survey was promoted to practitioners through national organisation official media channels and via international member networks and social media (Twitter, Facebook), and was open for approximately 5 months from March to August of 2022. Context data were extracted and summarised descriptively and text responses about future opportunities and challenges were collated into common themes.

RESULTS: A total of 750 people completed the survey, with 103 removed due to not having a tertiary degree background in SES, leaving 647 eligible responses. There were 37 discreet countries represented although the majority of responses (>90%) were from the ICSESP member countries of Australia, Canada, UK, USA and New Zealand. The predominant fields of practice were clinical exercise physiology (28%), exercise and sports science (25%), and Kinesiology (15%). The most common populations practitioners worked with were general healthy population (17%), musculoskeletal injury and disease (15%) cardiovascular disease (12%), sub-elite athletes (11%), metabolic disease (10%), and others including elite athletes, people with a disability, and people with a neurological disease, mental illness and cancers. The most pressing challenge identified was lack of recognition of the skills and qualification of SES practitioners, and the greatest opportunity was the increasing recognition of the role of exercise in improving and maintain health.

CONCLUSION: There is evidence of degree qualified practitioners of SES in many parts of the world. Issues faced by practitioners are common across the world, which support the value of the ICSESP in advocating for these professionals globally. The international community of SES practitioners, educators and researchers can work together to lift the profile of this industry and reduce the global burden of non-communicable disease.

A QUALITATIVE RESEARCH ON THE PARTICIPATION BEHAVIOR OF CHINESE DISABLED RUNNERS IN MARATHON

HUANG, D., LIANG, X., CHEN, X.

GUANGZHOU SPORT UNIVERSITY

Purpose – The purpose of this research is to explore the evolution process and formation path of marathon participation behavior of disabled people from injury to participating.

Design/methodology/approach –In this study, literature review, field investigation, case study and qualitative research method were adopted. Through multiple interviews with 8 disabled runners from 'Home of Hope' Rehabilitation Center for spinal cord injured Patients in Jiaxiang County, Shandong Province of China. The interview data were analyzed by open coding, axial coding and selective coding.

Findings –Results showed that: a) during the process of marathon participation, the disabled participants experienced respectively the trauma confusion period, individual transformation period, competition adjustment period and competition growth period successively. The changes in the four periods reflected the positive physical and psychological changes of the disabled participants, and finally reached a good result of accepting themselves and actively integrating with the society. b) In the process of marathon participation by the disabled, it occurred positive changes in values and psychological cognition. c) The external factors like family environment and social support, especially the family and friends, such as parents, spouses and friends, had a great role in promoting the mental health status of the disabled participants.

Practical implications –It is expected that this study can draw more attention to the disabled runners, a special group, in order to improve the service level and social support for this group of events so as to help disabled people build a positive lifestyle and help them actively integrate into society, and eventually promote the implementation of the 'Healthy China' strategy while improving the level of marathon running in the post-epidemic era.

Originality/value –The findings contribute to the following aspects. Firstly, this research found that the process of disabled participants participating in marathon was divided into four periods to explore the different psychological and behavioral characteristics of the four periods, which provides a theoretical basis for promoting the generation of disabled participants marathon behaviors. Secondly, it broadened the research of psychology and sports of the disabled. Thirdly, it confirmed the connection between marathon and physical and mental health of disabled people.

Limitation: Owing to the high physical requirements of the disabled runners and the inner sensitivity of some disabled runners, they do not want to be too disturbed in their own lives, so the number of people interviewed is limited. In addition, the current epidemic situation is relatively severe, and most marathon events are suspended because the epidemic does not allow large-scale gathering, which poses a certain challenge to the search of interviewees in this study.

INNOVATION IN SPORTS MEDICINE AND SCIENCE - A GLOBAL SOCIAL NETWORK ANALYSIS OF STAKEHOLDER COLLABORATION IN RUGBY UNION

ERSKINE, N., HENDRICKS, S., SALIE, F.

UNIVERSITY OF CAPE TOWN

Introduction: Innovation in sport is crucial for maximising athletes' health and performance. A key component of innovation is collaboration and engagement with stakeholders. Stakeholders may span multiple disciplines and sectors forming a network of interactions which drive the innovation. Therefore, gaining a better understanding of how stakeholders collaborate may provide a basis for enhancing future innovation success in sport. To investigate the network of stakeholders involved in rugby union research across the globe.

Methods: Using author affiliation listed on scientific publications, we identified the organisations that contribute to rugby union research. Co-authorship on scientific publications serves as an indicator of collaboration between authors from different organisations. Once the organisations were identified, we determined their location (country) and sector (healthcare, universities, professional sports teams, sport's governing bodies, industry, sports institutes, and science and support). Outcome measures included collaboration networks, degree centrality, betweenness centrality and inter-sectoral and intra-sectoral density. Collaboration networks were generated using UCINET for the years 2016-2020. In the network, each organization is represented by a node, while edges represent publications in which organizations collaborated. For each year, the top 5 organizations with the highest degree and betweenness centrality are reported. Organizations with high betweenness and degree centrality indicate collaboration and influence. High inter-sectoral and intra-sectoral density give an indication of interconnectedness within and between sectors.

Results: Actors producing knowledge were from the university (47%), healthcare (24%), professional sports team (9%) and sport's governing body (7%) and industry sector (3%), although industry plays a small role. Most actors are located in England, Australia, France, New Zealand, Ireland and South Africa (22%, 15%, 9%, 6%, 5%, 4%). Australian Catholic University, Leeds Beckett University, Stellenbosch University, Swansea University, University College London and the University of Cape Town are the most influential actors between 2016-2020 for rugby union innovation. Inter-sector collaborations show that Sports Governing Bodies are highly collaborative and act as a broker between actors across sectors.

Conclusion: We have shown that scientific knowledge for rugby union has been created at an increasing rate overtime and that the organisations that produce this knowledge are primarily located in countries that are Tier 1 rugby-playing nations and belong to the university sector. There is a preference for inter-sectoral collaboration with Sports Governing Bodies for knowledge creation, however, overall collaboration between and within sectors is inefficient. These results highlight an opportunity for collaboration as the organizations creating knowledge have been identified.

THE IMPORTANCE OF SOCIAL CAPITAL INDICATORS FOR MEMBER RETENTION IN SPORTS CLUBS IN TIMES OF PANDEMIC

BURRMANN, U., BRAUN, D., SIELSCHOTT, S.

HU BERLIN

Objectives: Even before the corona pandemic, more and more sports clubs reported declining memberships, episodic engagement, and difficulties in recruiting and retaining volunteers. Given the complex constraints on sports clubs and social activities during the corona pandemic, the question arises as to how this exceptional social situation affected membership retention in clubs and the importance of social capital. This lecture addresses a research gap by estimating membership commitment in the aftermath of the corona pandemic, focusing on the relevance of different social capital indicators.

Methods: The empirical analyses are based on a representative online population survey conducted in late 2020/early 2021. The survey sample comprises about 3200 persons 18 years of age and older, with a quota according to age, gender, education and region. In order to compensate for distortions of the sample compared to the population, the data were weighted by adjusting the socio-demographic characteristics to the corresponding data of the official statistics. The Effectiveness of the weighting is approx. 82 %. In order to establish comparability with other studies, items and scales from empirical studies of engagement and sports club research were used. In some cases, the items were modified to reflect the pandemic situation. The values for the internal consistency of the short scales are $\alpha = 0.61$ and 0.81, with one exception.

Findings: Membership retention of the sports club members remains quite high. Social capital indicators that are narrowly related to the sports club explain little in predicting member retention. In addition to perceived norms of reciprocity in the club, helpfulness and ingroup trust increase retention, while sociability orientation and outgroup trust decrease the likelihood of still being a member of the club after the pandemic. When all predictors are included, the model goodness of fit increases to almost 26%. In addition to a few sociodemographic characteristics, membership-related characteristics (e.g., crisis management of the association) contribute to the variance clarification. Willingness to help, outgroup trust, and a tendency towards sociability are the only significant social capital indicators in the overall model, although they contribute with considerable weights to the variance explanation.

Discussion and Conclusion: Solidarity orientations were already relevant predictors of member retention in other surveys. The Corona pandemic does not seem to have changed this. During the pandemic, however, the bridging potential of sports clubs seems to have suffered. The extent to which negative effects of a high social bonding capital are indicated here must be examined in further trend analyses. Preliminary conclusions but also limitations of the study are presented at the end.

DEVELOPMENT, VALIDATION AND UTILISATION OF THE TALENT DEVELOPMENT ENVIRONMENT QUESTIONNAIRE FOR PARENTS (TDEQ-P) TO HELP DRIVE EFFECTIVE TALENT DEVELOPMENT PROCESSES IN SPORT

MARTINDALE, R., FOUNTAIN, H., ANDRONIKOS, G., ENGLISH, C., DUGDALE, J., FERRIER, S.
EDINBURGH NAPIER UNIVERSITY

Talent development environments are multifaceted and dynamic, involving a range of stakeholders to ensure coherent messages are reinforced to young developing athletes as they progress. Parents are known to be important influences in the process but are often overlooked. As such, there is a need for coaches, clubs and NGBs to educate and foster relationships with parents of developing athletes. Furthermore, as part of an ongoing need to improve and reflect, it is important to provide opportunities for parents to feedback to coaches, clubs and NGBs. This may provide valuable insight helping coaches to understand the parents perspective better, educate parents about important TD processes, act as a mechanism to drive communication and build relationships. Importantly, it may also facilitate reflection from which improvements can be made. As such, this study aimed to design and validate the talent development environment questionnaire for parents (TDEQ-P). After adapting the wording of the original TDEQ questionnaire to make sense from a parents perspective, 485 parents of pathway athletes completed the questionnaire. The TDEQ-P included 28 items and two open ended questions related to perceived strengths and weaknesses of their childs TDE. The results showed support for a 28 item, 5 factor solution (Chi Square test x2 1039.342; DF 340; p< 0.001; CFI 0.993; RMSEA 0.065; SRMR 0.05), with robust discriminant validity and adequate internal reliability. The analysis of the TDEQ data and the open-ended questions provided both quantitative and qualitative feedback for coaches, clubs and NGBs to reflect upon in their drive for improved practice. The TDEQ-P is shown to be a valid, reliable and practical tool which could be used on its own or in tandem with the TDEQ for athletes to enable practitioners to glean feedback from key stakeholders within their talent development environment.

A STUDY ON THE RELATIONSHIP BETWEEN SPECTATORS BEHAVIORAL INTENTION AND SATISFACTION, EVENT QUALITY AND EVENT IDENTITY OF MEGA-EVENTS – THE 2019 WTA ELITE TROPHY ZHUHAI

LI, S.1, ZHOU, L.1, LIU, G.1, LIU, X.2, CHEN, X.1
1 GUANGZHOU SPORT UNIVERSITY 2 ZHUHAI HEALTH SCHOOL

Purpose – Taking the 2019 WTA ELITE TROPHY ZHUHAI as an example, this study aims to explore the relationship between spectator behavioral intention (BI) and event quality: core quality (CQ) and peripheral quality (PQ), event identity (EI), and satisfaction (SAT) of mega-events.

Methods – This study used a convenience sampling method to conduct a questionnaire survey of the on-site audience of the 2019 WTA ELITE TROPHY ZHUHAI, and 355 valid data were collected.The StataMP 17 structural equation model (SEM) was built and estimated (standardized) to compare the path coefficients, significance, and also the fit indices: root mean square error of approximation (RMSEA), standardized mean square residual (SMRM), comparative fit index(CFI), and goodness of fit index (GFI).Hypothesis based on the research model: (a) Hypothesis 1 (H1).EQ will positively influence SAT. (b) Hypothesis 2 (H2).EQ will positively influence EI. (c) Hypothesis 3 (H3).SAT will positively influence BI. (d) Hypothesis 4 (H4).EI will positively influence BI.

Results and Findings – The results support all hypotheses, with EQ and SAT (= 0.871, $p < 0.001$), being positively correlated, and EQ having a positive effect on EI (= 0.559, $p < 0.001$), supporting H1,H2, respectively. sat on BI (= 0.285, $p < 0.001$) and EI on BI (= 0.458, $p < 0.001$) Both were positively correlated, supporting H3,H4, respectively. Spectators of major sporting events perceived that event quality, satisfaction, and event identity all had positive effects on their behavioral intentions. Among them, satisfaction and event identity are direct influences on behavioral intention, while event quality indirectly influences behavioral intention through satisfaction and event identity.

Discussion – This study investigates the relationship between spectator behavioral intention and satisfaction, event quality and event identity, thus providing a new understanding and insight into the study of spectator behavioral intention in the fields of sports economics, sports marketing and sports management, which helps to better understand the mechanism of spectator behavioral intention formation of large sports events, so as to more effectively meet the needs of spectators and improve the quality of sports events. This will help to improve the quality of sporting events and the social impact of sporting events. The results of the study can provide reference for sport event organizers to better meet the needs of spectators, enhance the attractiveness of sport events, improve the satisfaction of events, enhance the quality of events, increase the recognition of spectators, and thus improve the market value of sport events.

INVESTIGATING THE ANTI-DOPING KNOWLEDGE AND EDUCATIONAL NEEDS OF REGISTERED PHARMACISTS

LEE, Y.C., HSU, M.C., CHANG, W.C.W.
KAOHSIUNG MEDICAL UNIVERSITY

Objective: Taiwan implements national health insurance, and the widely used Chinese herbal medicine (CHM) has many uses, such as diet therapy, health care, and disease treatment. This may increase the risk of athletes inadvertently using doping substances and being stripped of medals or ineligible from the competition. The prevention of sports doping requires the assistance of a pharmacist. This study aimed to understand the status quo of anti-doping knowledge and the education needs of licensed pharmacists in Taiwan and to explore the reasons for these differences.

Method: A cross-sectional study was conducted using an anonymous online questionnaire survey. The questionnaire has five sections: demographic characteristics, source of prohibited substances, identification of prohibited substances, and understanding of education needs on anti-doping. It was distributed to registered pharmacists in Taiwan. Analyses were performed using SPSS version 20.0 using chi-square, independent sample t-test, and one-way analysis of variance (ANOVA) to determine associations and differences among the interviewed pharmacists' demographics, anti-doping knowledge scores, and educational needs.

Results: The respondents were 491 pharmacists, 64.6% female, aged 41.9 ± 11.4 years, and 68.4% with bachelor's degrees in pharmacy. Respondents' knowledge scores on sports doping were negatively correlated with age, with younger respondents having higher knowledge scores ($p < 0.001$). Respondents in southern Taiwan (vs. northern Taiwan) and those working in clinics (vs. hospitals) had less knowledge of sports doping. Only 38.3% of the respondents knew that furosemide was prohibited in sports, and CHM (7%) containedβ2 agonist higenamine. On average, respondents scored 73.02 ± 9.63 points on a scale of 0-100. Among them, 71.5% of the respondents exhibited moderate anti-doping knowledge (between 50-79 points). More than 90% of the respondents indicated that they needed to participate in sports doping education courses.

Conclusion: There are differences in anti-doping knowledge among licensed pharmacists, and they have a high willingness to accept sports doping education courses and to provide directions for planning the theme of sports doping education courses in the future. benefit and improve drug safety and health for the general public and athletes.

CP-SH01 Physical Education

PHYSICAL ACTIVITY ON PRESCRIPTION 'NOT A QUICK FIX': SCHOOL NURSES' EXPERIENCES OF PROMOTING AND TAILORING PHYSICAL ACTIVITY TO CHILDREN IN SWEDISH COMPULSORY SCHOOL

WIKLUND, E.
SPORT SCIENCE

Introduction

The number of children who reach the recommendations for physical activity (PA) is decreasing globally (1). Physical activity on prescription (PAP) is an individually written recommendations of PA. It can be used in school by school nurses to support children who do not reach the health recommendation for PA and are at risk of illness (2). The prescription can include individualised PA, for example, everyday exercise or organised PAP activities led by an activity organizer or sport clubs after school. Since school nurses provide PAP in school, they have an important role in evaluating PAP´s effectiveness. Therefore, this study aimed to explore school nurses' experience of using PAP with children in compulsory school.

Methods

In this study, semi-structured individual interviews were conducted with 24 school nurses who had the competence to prescribe PAP. Qualitative content analysis with an inductive approach was used. To understand how different system levels influence when prescribing PAP, Bronfenbrenner's ecological systems theory has been used.

Results

The analysis resulted in one overarching theme: 'A delicate process of tailoring physical activity on prescription to a child social context', and two categories: 'Promoting joyful physical activity through individualisation and support' and 'Dealing with dilemmas and challenges', with related subcategories. The results demonstrate the importance of tailoring prescriptions of physical activity to each individual child, their living conditions, and the school context.

Discussion

The results demonstrate that school nurses' use of PAP with school children is not a 'quick fix'. Using PAP in school is a complex and delicate process of tailoring to the needs and social conditions of each child. In congruence with the Convention on the Rights of the Child (3), it is important that children are involved and participate in deciding which PA they will perform. Physically inactive children, without a sports background, often request activities based on their own interests, such as playing, walking or jumping (4). Such PA is possible to obtain via a PAP and is in line with the school nurses thoughts about individualising the PAP.

CONCEPTS AND DEFINITIONS OF RACISM IN PHYSICAL EDUCATION: A SCOPING REVIEW

GALLE, A.C., ABEL, L., VOGT, T.

GERMAN SPORT UNIVERSITY COLOGNE

Introduction

Racism is a ubiquitous entity in society. Not only can the phenomena be found in everyday life, but also does it illustrate a common entity in Physical Education (PE). Researchers who investigate structures of racism in PE need to draw on theoretical outlines to support their investigation. Thus, by addressing racism in PE studies from different perspectives (i.e., pupils, teachers, researchers), the aim was to elaborate the existence of consistent racism concepts and definitions, respectively.

Methodology

A scoping review was conducted with PRISMA standards. Article selection was based on three criteria: a) peer-reviewed journals b) keywords (e.g., racism, PE) targeting international (i.e., English) or national (i.e., German) publications, respectively, and c) pupil, teacher, or researcher-centred studies. Lastly, included studies from eleven databases were analysed according to a framework analysis.

Results

In total, 5213 articles were found with 53 (pupils n=16, researchers n=22, teachers n=22) meeting the set inclusion criteria; overall, 23 coding categories were generated with articles allocated to different codes and categories.

The pupils' perspective mostly refers to the concept of the racialized 'other' 20% or, less prominent and mostly applied, to the concept of racist stereotypes 15% and the idea of biological racism 10% or institutional racism 10%. The researchers' perspective frequently mentions the notion of Whiteness as a race or ideology 18 %, followed by the concept of the racialized 'other' 17 % and the Critical Race Theory (CRT) 9%. The teachers' perspectives align with the researchers' perspectives, except rather drawing on the concept of racist stereotypes 11% than on the CRT.

Discussion

Evidently, for different perspectives in PE there is no unified concept or definition of racism that is ingrained in the numerous aspects of life marking diversity (e.g., politics, social practices, Gender Studies). However, Whiteness as an ideology is often put into relation with the concept of the racialized 'other' [1]. That is to say that Whiteness is seen as the highest norm which operates to normalise and naturalise the 'other.' It prevents 'others' from seeing their own individuality and thus subtly, as overtly perpetuates the idea of a racialised and inferior 'other' [2].

To conclude, the scoping review illuminates various possibilities of defining racism while illustrating similarities with respect to different perspectives in PE. We are confident that the more we debate racism, the more likely it is to generate new voices who stand against it.

HEALTH PROMOTION FOR APPRENTICES IN THE CRAFTS SECTOR - A THEORY-BASED BLENDED LEARNING HEALTH PROMOTION INTERVENTION IN VOCATIONAL SCHOOLS

FÜLLGRAEBE, F., BIALLAS, B.

GERMAN SPORT UNIVERSITY COLOGNE

Background: Current and future public health and health policy challenges demonstrate the need for quality-assured prevention and health promotion. Apprentices in the crafts sector have been rarely selected as target group for health promotion interventions, although their state of health can be considered as a cause for concern. Hence, the objective is to develop a quality-assured health promotion intervention for apprentices in the crafts sector that can be implemented in vocational schools on a long-term basis and can serve as a driver of sustainable behavioural change.

Method: The blended learning health promotion intervention was designed evidence-based according to the holistic approach. As first step, the problem definition was specified systematically to identify the current state of research. Subsequently, the strategy was derived. Additionally, a workshop with relevant stakeholders from science, industry and government was conducted in order to define the methodological and content-related cornerstones. Based on this, the health promotion intervention was elaborated and implemented at vocational schools.

Results: The theory-based blended learning health promotion intervention #missionmacher - get fit for your future was developed and implemented in vocational schools. Four teaching units were developed on the subjects of self-management skills, stress management skills, nutritional behaviour as well as exercise and regeneration behaviour. Teachers were provided with a comprehensive set of ready-to-use teaching materials. The intervention starts with a health day at the respective vocational schools facilitated by experts. In addition to the health day and teaching units as face-to-face interventions, a digital application was designed to be used in both, school classes and in the students free time. The digital content includes quizzes as well as physical and behavioural challenges. Additionally, a podcast series on stress management and videos to support behavioural change were developed.

Discussion: #missionmacher - get fit for your future is a theory-based health promotion intervention with a comprehensive set of face-to-face and digital content. It was developed in stakeholder-oriented and resource-efficient way to consider the limited time resources of the apprentices and teachers. Subsequently, it was optimised according to the needs and wishes of the involved stakeholders in a participative mode. In future interventions, the target group and multipliers should be involved at an earlier stage in order to consider their needs and interests right from the beginning. This results in a higher level of quality and reduces subsequent change requests. As craft apprentices are a small target group in vocational schools, a transferability assessment should be carried out and tested to expand the target group.

THE INFLUENCE OF THE INITIAL MOTIVE SITUATION ON MOTOR LEARNING PERFORMANCE IN RELATION TO POSITIVE AND NEGATIVE REINFORCEMENT

SCHRÖDER, S.

OTTO VON GUERICKE UNIVERSITY MAGDEBURG

The influence of the initial motive situation on motor learning performance in relation to positive and negative reinforcement

Schröder, S. Otto von Guericke University Magdeburg

Introduction

The question of the effectiveness of successful coach instructions is not only very important in competitive sports, but also an elementary part of learning new motor skills. The different successes of the coaches as well as an observable large influence of the mental processes on the learning performance illustrate the necessity of considering existing motive structures for sporting success. The aim of the present study was to show dependencies between existing achievement motive structures and motor learning performance as a function of positive or negative reinforcement.

Method

13 participants who are between 16 and 19 years old and do competitive sports were examined (girls=5, mean age=16.8, boys=8, mean age=16.88). It was assumed that nobody had previous experience in juggling, so that there was no specific starting level. The groups were questioned with the help of the UMS-10 (German, Schönbrodt, F.D., & Gerstenberg, F.X.R., 2012) regarding their achievement motive expression (Cronbach's α usually >.75). The participants were randomly divided into two groups, which watched a 6-step instructional juggling video while actively following the methodical steps with standardized balls (ball=100g; 62mm). In addition, skin conductivity was measured using biofeedback in order to establish dependencies to possible stress reactions (Biograph InfinitiTM Software, ProComp Infiniti System).

results

The two randomized groups showed major differences in learning performance. The positively reinforced group (N=7; *M*=5.13, SD=0.38) differed from the negatively reinforced group (N=6, *M*=4.58, SD=1.11). No significance could be determined, which was probably due to the small sample. In addition, a large difference in skin conductance was measured, which was higher in the positively reinforced group (positive group: *M*=8.91, SD=4.86 and negative group: *M*=4.12, SD=3.99). The T-test for independent samples showed no significance (p=.07).

Furthermore, it could be shown by means of a co-variance test that the learning performance depends on the initial motive situation if the learning process is positively or negatively reinforced.

discussion

The present study is to be understood as a pilot project, which is to be followed by a larger sample. This ensures that there are generalized statements on the dependencies of learning performance on the motivation structure of the athletes and on the instructions of the coaches. This requires a larger sample so that the same number of genders and a comparable starting point for motives is also present in the two groups due to the randomness. Furthermore, a larger sample and further biofeedback data should show dependencies between the trainers instructions, the initial motive situation and the learning performance.

RELATIONSHIP AND DIFFERENCE BETWEEN INTRINSIC MOTIVATION CLIMATE OF PE LESSONS AND PHYSICAL ACTIVITY (PA) OF HIGH SCHOOL STUDENTS

GHAZVINI, N., HAMAR, P., SOOS, I.

HUNGARIAN UNIVERSITY OF SPORTS SCIENCE

Relationship and difference between intrinsic motivation climate of PE lessons and physical activity (PA) of high school students

Ghazvini, N., Hamar, P. and Soos, I

Hungarian University of Sports Science

Introduction

Motivation is considered to be one of the most essential factors associated with engagement in physical activity throughout childhood and adolescence (Hagger and Chatzisarantis, 2007; Sallis et al., 2000). The study of motivational processes in sports for adolescents is crucial because their PA level decreases by age, annually by 7% (Chu & Zhang, 2018). The aim of this study was to investigate the relationship between MCPES's variables and PA of Iranian female high school students and the differences in motivational components of students PA.

Methods

The sample consists of 295 Iranian female students between 13-15 years of age. Participants were selected from 5 schools (wealthy, moderate, and lower income districts) they filled out the intrinsic motivation climate of PE lessons questionnaire (MCPES), international physical activity questionnaire (IPAQ), and general information, demographic data questionnaire online. The ethical committee of the Hungarian University of Sports Science granted permission for this study. The MCPES (Soini et al.,2014) consists of four subscales comprising Ego/competitive, Task involving, Social relatedness supporting and Autonomy supporting climate on a 5-point Likert scale (anchored from not at all important=1 to extremely important=5). The IPAQ consists of three levels of PA (low, moderate, and high levels) which were measured based on MET. The low level was less than 600 MET, moderate level was between 600 to 3000 MET and high level was at least 3000 MET. For data processing IBM SPSS v. 26. software was used. Descriptive statistics indicators (frequencies, mean and standard deviation were reported. Furthermore, in order to determine the relationships and differences between variables, Spearmans rank correlation coefficient, as well as Kruskal-Wallis tests were performed respectively.

Results

The results showed a significant positive relationship between PA and ego, task, social, autonomy, enjoyment, and physical activity. There were significant differences in the levels of students PA influenced by intrinsic motivational climate in PE. In addition, with the increase of motivational climate in PE lessons, levels of students' PA increased as well ($p \leq 0.05$).

Discussion and conclusions

The findings of this study revealed that variables of subscales of MCPES (including ego, task, social relatedness supporting, autonomy supporting climate) and even enjoyment and physical activity that are not part of MCPES have a significant positive relationship with PA. Also, with the increase in PA levels of the students, the amount of MCPES's variables increased, and a significant difference was observed between MCPES's variables and PA of the students. In summary, based on the findings of the present study, conclusion can be drawn that intrinsic motivational climate in PE, which is examined by the theory of goal orientation, is an effective and reinforcing factor for doing PA.

Keywords: MCPES, IPAQ, Iranian female students

PROMINENCE OF BASIC SWIMMING SKILLS IN GERMAN CHILDREN'S BOOKS

VOGEL, M., STAUB, I., KRONENBÜRGER, S., VOGT, T.

GERMAN SPORT UNIVERSITY COLOGNE

Introduction

Previous research on British children's books has shown that they may serve a transfer of knowledge to society but create a distorted representation of the importance of required water competencies (i.e., submerging, floating, gliding [1]). Considering possible cultural differences in the learn-to-swim process, this study aims to investigate how essential water competencies are addressed in German children's books.

Methods

The selection of children's books is based on the principle of the most up-to-date and well-known works, with no further restrictions on the selection. Thus, 9 books were identified eligible for the analysis of this study. The analysis is limited to the macroanalysis of the content and representation of the text and pictures as well as their interdependence [2].

Results

The basic skill submerging, initially and not as part of a swimming technique, is described in detail in 56% of the books, of which submerging is illustrated in 44% by retrieving an object, however, with varying degrees of detail (e.g., eyes are always shown open except once when goggles are used). Floating is addressed in 67% of the books, described as both, floating on front and back; gliding is depicted in 22% of the books. Often, it's either gliding or floating, but mostly the protagonists learn propulsion. A distinction must also be made whether buoyancy aids are used or not. In addition, the books vary in representing the head's posture.

Discussion

Submerging is portrayed in the children's books congruent with scientific literature. One reason for such prominent consideration is certainly the importance of submerging, since this is not only a prerequisite for learning to swim, but in Germany also one task of the first swimming badge. Floating and gliding, on the other hand, is scattered depicted in the German children's books. A scientific discussion of the methodological steps necessary to learn the two basic skills of floating and gliding does not take place in any of the books. It can be assumed that the German swimming badges may

lead to a shift in the importance of basic swimming skills. Future studies may consider the choice of the first swimming technique in children's books.

PROMOTING STUDENTS' HEALTH THROUGH PHYSICAL EDUCATION WITH DIGITAL METHODS: A SYSTEMATIC REVIEW

KNOKE, C., WOLL, A., WAGNER, I.

KARLSRUHE INSTITUTE OF TECHNOLOGY

Introduction

Young peoples engagement with digital health technologies is often discussed in terms of risk. However, there is limited evidence on the problems and opportunities that can arise from digital health technologies (Goodyear et al., 2018). The use of digital media in physical education can support and optimize teaching and learning processes (Gómez-García et al., 2016). Therefore, the aim of the current systematic review was to identify the state of research on digital methods for promoting students health in physical education.

Methodology

In order to address the research question of what research is already available on health promotion using digital media in physical education, a literature review of English language studies was conducted. The literature search was performed from July 2022 to December 2022 in the databases Web of Science, ERIC, Scopus and PubMed. A sample size of N=1492 studies was included in the analysis at baseline.

Results

After title, abstract, and full text screening, N=47 empirical studies were included in the literature review. The results show, among other things, that digital media can impart knowledge in physical education with similar results without the need for a teacher. Furthermore, digital categories such as gamification are reported to increase intrinsic motivation and fun on the part of school students. Digital media can also appeal to different types of students in physical education, making it possible to reach previously less responsive students.

Discussion

Schools, physical education classes, and peers are important contexts in which to foster the development of effective pedagogy by examining how young people use digital health technologies. In order to take advantage of digital applications with the goal of promoting health in physical education, results show a need for empirically tested implementations regarding the school setting.

EMPIRICAL FINDINGS ON STUDENTS EMOTIONAL EXPERIENCES OF MASTERING JUMPING TASKS IN PHYSICAL EDUCATION

AHNS, M., FILZ, L., AMESBERGER, G.

UNIVERSITY OF SALZBURG

Introduction

Emotions interact with motivational consequences in physical education. Emotional experiences are shaped by situational contexts, social conditions and subject matter (Ahns, & Amesberger, 2021). While empirical studies focus on general emotional experience in PE and pay little attention to the specific content or task context (e.g., Leisterer, & Jekauc, 2019), the aim of the present study is to elaborate facets of emotional experience in close relation to a specific subject matter. We ask, how students experience jumping tasks emotionally.

Method

We taught a didactic lesson at a sixth grade in an Austrian high school that focused on offering different open tasks of jumping with the aim of encouraging self-referential goal setting and to foster emotional experiencing. Subsequently, 12 (6m/6f) episodic narrative interviews (Mueller, 2019) were conducted. For analysis, the documentary interpretation (Nohl, 2010) is used to reconstruct orientation patterns of students, describing their emotional experience.

Results

Analyses show that jumping in general spans a wide emotional range from aversive to joyful, while some students also experience it as unemotional. In particular, the experience of mastering a jumping task is emotionally charged: students

explicitly and implicitly refer to fearful situations (e.g., height, unsafe tread, social pressure) or making the decision to jump as emotion-triggering moments (i); they describe the task-related action emotionally as states of clutch or as an intense perception of the emotion (e.g., trembling legs) (ii); and they emphasize the experiential qualities of fulfilling or mastering a jumping task (e.g., unexpectancy comes with pride or shock) (iii).

Discussion

The results show that the emotional experiencing is formed along specific subject matter, respectively that students differ in how they reference their experience (i-iii). Didactical implications should consider ways of individual accompaniment of the emotinal experience to unleash motivation, e.g. to create awareness of implicit emotional triggers or to strengthen joyful action orientation.

A STUDY ON THE CORRELATION BETWEEN LEARNING EFFECTIVENESS AND SPORTS ENJOYMENT AMONG ELEMENTARY SCHOOL CHILDREN IN THE NORTH OF TAIWAN

CHIAMIN, W.1, MENGSHYAN, L.1, HUIFANG, W.1, HUIING, H.2

SOOCHOW UNIVERSITY.1, NATIONAL ILNA UNIVERSITY.2

Introduction: Physical education programs often give people the impression that they are tool- and skill-oriented, emphasizing "content" at the expense of "students," and lacking the function of encouraging students to take action to improve their own physical fitness, not to mention improving the environment in which people live, exercise, relax, and work, and promoting community development. Therefore, we explored the current situation of sports enjoyment and learning effectiveness of P.E. classes among elementary school children in the Northern part of Taiwan after the implementation of the 12-year National Curriculum.

Method: In this study, elementary school students in Northern Taiwan were used as the independent variable, and their learning effectiveness and sports enjoyment were used as the dependent variables. The learning effectiveness variables in this study included cognitive, affective, and skill categories; the sport enjoyment variables included social opportunities, sport enjoyment, social identity, and health needs. The questionnaire was distributed in September, 2022. 1,500 questionnaires were randomly distributed by stratified random sampling of which 117 invalid questionnaires were excluded, resulting in 1,383 valid questionnaires.

Result: The KMO value and Bartletts spherical check method were used to understand the appropriateness of sampling, and the result of the KMO value was .82 and the Bartletts value of 3346.04 also reached a significant level. The internal consistency coefficient of the first factor "parental support" was .90; the internal consistency coefficient of the second factor "teacher support" was .88; and the internal consistency coefficient of the third factor "classmate support" was .94. Overall, the coefficient values of this study ranged from .88 to .95, which is considered high. The Cronbach alpha value for the total scale was .94.

Discussion: The study showed "cognitive", "affective", and "skill". The factors of "cognitive", had the highest importance over "affective", and "skill". The factors that contributed to the enjoyment of physical education for elementary school children in Northern Taiwan included "social opportunities," "sports enjoyment," "social identity," and "health needs. The four factors were "social opportunities", followed by "social identity", "health needs", and "sports enjoyment". This result is the same as that of Guo Yisan (2015). The reason for this is that Guo Yisans (2015) study was conducted on upper elementary school students in Taipei City, and the result was that self-orientation was positively related with extrinsic/achievement in sports enjoyment, indicating that students are more mentally developed at the junior high school level, and they are still able to experience the sports enjoyment by training hard for their own competition.

CHILDREN'S NEED FOR PHYSICAL ACTIVITY IN PHYSICAL EDUCATION - A CROSS-SECTIONAL SURVEY OF PRIMARY SCHOOL TEACHERS.

MACKENBROCK, J., KLEINERT, J.

GERMAN SPORTS UNIVERSITY COLOGNE

INTRODUCTION: Physical activity (PA) is important for children´s development and is associated with many positive effects (e.g. better academic performance). Especially in children of primary school age, a high need for PA or a high urge to move is often reported. However, it is unclear which characteristics can be used to operationalize the need for PA. As experts on this topic, physical education (PE) teachers in primary schools can provide information on how the need for PA

is expressed. As an exploratory approach, this study aims to get an overview of the characteristics that primary school PE teachers use to identify a high or low need for PA and whether they rate it as good or bad, helpful or disturbing.

METHODS: Primary school PE teachers were asked to participate in a cross-sectional online survey. Besides demographic information, teachers were asked to name signs for high or low need for PA before PE lessons, during passive phases in (e.g. exercise explanation) PE, during active phases (e.g. exercise execution) in PE and after PE lessons based on their experiences (qualitative data). All mentions were analyzed in an inductive and deductive analysis and assessed according to their frequencies. In addition, the PE teachers were asked to what extent a high or low need for PA is good or bad for the student and the achievement of learning goals, and how helpful or disturbing it is for the PE lessons and the classmates (quantitative data on seven-point scales: 1 good/helpful - 7 bad/disturbing).

RESULTS: 70 primary school PE teachers (female = 59; male = 11) with a mean age of 45,69 (SD = 7,96) participated in the online survey. The need for PA can be observed in all PE-phases (before, during, after). Three categories could be derived from the mentioned signs of PA-need identification: PE-environment-related (e.g. interaction with classmates or materials), person-related (e.g. physical signs), task-related (e.g. performance).

The PE teachers rated a high need for PA rather positively to medium (for student M = 2,06, SD = 1,12; for achievement of learning goals M = 2,60, SD = 1,32; for PE M = 2,14, SD = 1,11; for classmates M = 3,13, SD = 1,51). A low need for PA was rated rather negatively to medium (for student M = 5,50, SD = 1,09; for achievement of learning goals M = 5,33, SD = 1,46; for PE M = 5,26, SD = 1,26; for classmates M = 4,96, SD = 1,30).

Discussion:

The categorization shows that the need for PA is expressed at/in different times and ways. Thus, teachers should focus on students´ behavior during whole PE. This is supported by the fact that teachers tend to rate a high need for PA positive and a low negative for PE. Raising awareness for observing PA-need can therefore help to ensure that PE is adequate for students and psychological variables like motivation or self-efficacy can be promoted individually.

Further research is needed to theoretically substantiate the need for PA in children and to systematize the measurement.

COMBINED EFFECTS OF ELECTRICAL MUSCLE STIMULATION AND CYCLING EXERCISE ON COGNITIVE PERFORMANCE

KANO, K., ISHIOKA, Y., KANBAYASHI, S., COSTELLO, J.T., SUDO, M., ANDO, S.

THE UNIVERSITY OF ELECTRO-COMUNICATIONS

INTRODUCTION: Acute aerobic exercise has been shown to improve cognitive performance. We have recently reported that a combination of electrical muscle stimulation (EMS) to lower limbs and arm cranking exercise improves cognitive performance [1]. However, acute effects of a combination of EMS and cycling exercise on cognitive performance remains to be elucidated. In the present study, we hypothesized that a combination of EMS and cycling exercise improves cognitive performance. The purpose of this study was to test if a combination of EMS to lower limbs and cycling exercise improves cognitive performance.

METHODS: Eighteen participants (7 females) were recruited in this study. The participants performed a Go/No-Go task before and after 20 minutes of 1) a combination of EMS and cycling exercise (EMS+EX), 2) cycling exercise (EX), and 3) rest (Control). EMS was applied to bilaterally to the abdomen, glutes, thighs, and lower legs with an electrical stimulator at 4 Hz (Auto Tens Pro; Homer ion, Tokyo, Japan). Exercise intensities in the EMS+EX and EX conditions were adjusted so that heart rate (HR) was maintained at 120 beats per minute (bpm). Cognitive performance was assessed using reaction time (RT) and percentage of correct responses. We performed two-way of analysis of variance with condition and time (pre vs. post) as factors. Bonferroni correction was applied to correct for multiple testing.

RESULTS: Mean HR was 120.3 ± 1.4 during EMS+EX and 120.6 ± 0.5 bpm during EX, which indicates that HR was matched between EMS+EX and EX conditions. We observed a significant interaction on RT ($p = 0.007$). Cognitive performance tended to improve after cycling exercise (Pre: 335 ± 31 ms, Post: 327 ± 25 ms, $p = 0.031$). However, cognitive performance did not change after the combination of EMS and cycling exercise (Pre: 333 ± 28 ms, Post: 327 ± 29 ms, $p = 0.24$). Accuracy of cognitive performance was not altered in all conditions ($p > 0.11$).

CONCLUSION: Acute cycling tended to improve cognitive performance (i.e. selective attention and response inhibition). However, despite similar HR, cognitive performance did not change in the combination of EMS and cycling exercise. These results suggest that effects of EMS with cycling exercise are different from those of cycling exercise. Furthermore, the present findings are not consistent with our previous results showing that the combination of EMS and arm cranking exercise improved cognitive performance. Collectively, the present findings suggest that that neural activations during EMS with cycling exercise may be insufficient to improve cognitive performance.

PREFERRED DIRECTION OF ELECTROMYOGRAPHIC ACTIVITY OF THE HIP ADDUCTORS DEVIATES FROM THE ANATOMICAL LINE OF ACTION

TOZAWA, H.1, KAWAMA, R.1,2, WAKAHARA, T.3

1 GRADUATE SCHOOL OF HEALTH AND SPORTS SCIENCE, DOSHISHA UNIVERSITY, KYOTO, JAPAN

INTRODUCTION: The hip adductors [adductor magnus (AM), adductor longus (AL), and gracilis (Gra)] have functions of hip extension and flexion as well as adduction (1). The hip joint is a joint with a high degree of freedom of movement and thus we can exert force in various directions at the joint, such as a combination of extension and adduction. However, little is known about which direction of force exertion will show high electromyographic (EMG) activities in the hip adductors. This study aimed to investigate the preferred direction (PD) of EMG activities in the hip adductors by comparing PD with adduction (0°) and with the lines of action anatomically determined in the previous study (1).

METHODS: Eighteen healthy young males performed maximum voluntary isometric contraction (MVIC) for 3 s in five directions [1) hip flexion (90°), 2) flexion + adduction (45°), 3) adduction (0°), 4) extension + adduction (−45°), 5) extension (−90°)] at 0° of hip flexion and 90° of knee flexion. Surface EMGs were recorded from AM, AL, and Gra. The electrode positions were carefully determined using ultrasonography according to a previous study (2). The exerted force was measured using a load cell. The direction of the load cell was measured from recorded video during MVIC and used as the direction of the force. Root mean square (RMS) of EMG was calculated for 1 s during MVIC for each muscle. The RMS and the direction of the force were plotted in a polar coordinate system as radius and angle from the polar axis, respectively. The centroid of the polar coordinates of the five MVICs was calculated for each muscle. The angle of the centroid in the polar coordinate system was defined as PD of each muscle. The Wilcoxon signed-rank test was used to analyze the differences between PDs and adduction (0°) and between PDs and the anatomical lines of action [AL: 30.0°, AM: −59.6°, Gra: 10.4° (1)]. Data were presented as median (interquartile range).

RESULTS: The PDs of AL [19.8 (15.9 to 27.1)°] and AM [−38.2 (−48.7 to (−32.0)°)] were significantly different ($p < 0.001$) from adduction (0°). Meanwhile, there was no significant difference ($p = 0.276$) between PD of Gra [−3.5 (−12.3 to 3.8)°] and adduction (0°). In addition, PD of AL, AM, and Gra was significantly different from the anatomical line of action in each muscle ($p < 0.001$ to $p = 0.002$).

CONCLUSION: The PD of AL was inclined to flexion and that of AM was inclined to extension compared to adduction (0°). Although AL and AM have been considered as adductors, this study showed that their PDs of EMG activity deviated from "adduction". Additionally, PDs of AM, AL, and Gra were inconsistent with the anatomical lines of action (1). These results suggest that the physiological characteristics of hip adductors are different from the anatomical characteristics.

DYNAMICS OF NEUROMUSCULAR ADJUSTMENTS TO THE PROGRESSIVE REDUCTION OF EXTERNAL FORCES

FAZZARI, C.1, MACCHI, R.1,2, CASANOVA, R.1, NICOL, C.1, CHAVET, P.1

1 AIX-MARSEILLE UNIV, CNRS, ISM, MARSEILLE, FRANCE; 2 INSEP, SEP-EA 7370, PARIS, FRANCE

INTRODUCTION: Previous studies have investigated the running pattern adjustments to sudden perturbations, such as unexpected changes in terrain stiffness or height (1). Interestingly, lower body positive pressure treadmills (LBPPTs) allow for progressive unweighting. During the transition phase, positive correlations have been reported between changes in braking force and changes in vasti and soleus muscle activity (2). However, these correlations have not been examined separately for each participant. The current study investigated the dynamics of neuromuscular adjustments to the progressive reduction of external forces, considering individual differences.

METHODS: Forty men (19±1yr) ran on a LBPPT at 100 and 60% body weight. The unweighing transition included 18±3 right strides. Normal ground reaction force and surface EMG activity of 11 lower limb muscles were averaged over the braking phase and normalised to their mean value recorded at 100% body weight. Spearman's correlation tests were used to quantify the relationship between the normalized braking force and EMG activity during the unweighting transition phase. Chi-squared tests were used to compare the proportions of positive and negative significant correlations.

RESULTS: Braking force was positively correlated with VM (ρ=0.67±0.11), VL (0.66±0.10) and RF (0.68±0.10) activity in 65, 60 and 63% of the participants, respectively. It was negatively correlated with STSM (-0.67±0.10) and BF (-0.68±0.10) activity in 50 and 28% of them. Braking force was positively correlated with shank muscle activity in few participants (<13%), but negatively correlated with SOL (-0.59±0.13), GaM (-0.58±0.15), GaL (-0.70±0.15), TA (-0.59±0.10) and PL (-0.63±0.10) activity in 8, 13, 28, 23 and 25% of them. Positive correlations predominated for the quadriceps (VM: X^2=26, VL: 21.2, RF:25, p<.001), whereas negative correlations predominated for the hamstrings (STSM: X^2=20, BF:20, p<.001) and three shank muscles (GaL: X^2=6.4, TA: 6.2, PL: 3.8, p<.05).

CONCLUSION: The progressive reduction of external forces mainly affected thigh muscle activity. It showed a decrease in quadriceps activity, as previously reported (2), but an increase in hamstring activity in most participants. Operating in the optimal range of their force-length relationship, the hamstrings may have contributed to the reduced peak knee flexion during the stance phase (3). On the other hand, unweighting resulted in opposite adjustments in shank muscle activity between participants. Nevertheless, their activity increased in most of them, suggesting an increased ankle stabilisation.

This is attributed to the shift towards a more forefoot strike pattern (3). This adjustment appears be transient as it is no longer observed after 3 minutes of unweighted running (4).

THE EFFECT OF EXERCISE-INDUCED MUSCLE DAMAGE ON RUNNING BIOMECHANICS AMONG HIGHLY-TRAINED RUNNERS

MARKUS, I.1, ARUTIUNIAN, A.1, DELLO IACONO, A.2, GEPNER, Y.1

1. TEL-AVIV UNIVERSITY, TEL-AVIV, ISRAEL. 2. UNIVERSITY OF THE WEST OF SCOTLAND, HAMILTON, UK.

INTRODUCTION: The metabolic and inflammatory responses induced by downhill running are well known. Yet, the resulting muscle damage and its influence on biomechanics remain unclear. This study aimed to examine the effects of exercise-induced muscle damage (EIMD) on running biomechanics across a 48-hour recovery period post-exercise.

METHODS: Twenty-six (33.8 ± 9.17 years, 76.2 ± 11.5 kg, 24.8 ± 3.26 kg/m2) healthy participants completed four experimental sessions. The first session participants completed maximal O2 uptake test and anthropometric measurements. Within 14 days, participants performed 60 minutes of downhill running (slope: -10%) at 65% of maximal heart rate. Before (BL), immediately-post (IP), after 24-hour (24H) and 48-hour (48H), participants underwent biomechanics assessments on an instrumented 3D treadmill to investigate changes in kinetic responses (first and second peak of ground reaction forces [GRF] magnitude). Blood markers (i.e., creatine kinase, lactate dehydrogenase and C-reactive protein) and subjective questionnaires by the means of a visual analog scale (VAS) were measured up to 48H post-protocol. Magnetic resonance imaging (MRI) of the quadriceps muscle were performed at BL, 1H and 48H to measure muscle integrity. Mixed-effects models were used to examine differences across all time-points.

RESULTS: Compared to BL, significant decreases in the magnitude of first GRF peak of the left leg were found at IP (-454.01N, $p = 0.015$), 24H (-420.37N, $p = 0.026$) and 48H (-396.14N, $p = 0.033$) while the second GRF peak showed significant decreases at IP (-532.8N, $p = 0.020$), 24H (-524.7N, $p = 0.023$) and 48H (-498.2N, $p = 0.029$) compared to BL. The right leg showed a significant decrease of the first GRF peak at IP (-348.4N, $p = 0.036$), while A significant decrease was observed in the second GRF peak at IP (-467.44, $p = 0.019$) and 24H (-396.89, $p = 0.049$). Significant (all $p < 0.05$) negative correlations were observed between CK concertation at IP and changes in the second GRF peak in both right ($r = -0.685$ and -0.509) and left ($r = -0.701$ and -0.562) legs at 24h and 48h respectively. No significant associations were found between running biomechanics and muscle integrity or subjective perception.

CONCLUSION: Biomechanics measurements remain impaired up to 48 hours following EIMD. These effects are associated with markers of muscle damage and biochemical stress.

RELATIONSHIP BETWEEN THE INITIAL DORSIFLEXION ROM AND THE GASTROCNEMIUS ACTIVATION DURING HEEL DROP STATIC STRETCHING.

OLIVEIRA, L., KLUJSZA, L., BRANDÃO, M.C., ALBARELLO, J., CABRAL, H.V.

UNIVERSIDADE FEDERAL DO RIO DE JANEIRO

INTRODUCTION: Heel drop static stretching (HDSS) has been commonly applied in gyms and rehabilitation clinics with the purpose of increasing the range of motion (ROM) during ankle dorsiflexion. However, distinctly from other static stretching exercises, HDSS has an eccentric component (1) which may induce a different neuromuscular response of the triceps surae. Indeed, recent evidence has demonstrated an acute increase in the gastrocnemius stiffness following HDSS (1). The purpose of this study was to investigate whether there is an association between gastrocnemius activation during the HDSS and the values of ROM and maximum voluntary isometric torque (MVC) before and after HDSS.

METHODS: 21 participants (10 men) performed 3 sets of 60 s of unilateral HDSS on the dominant leg. Before and after the HDSS the plantar flexion MVC and the dorsiflexion ROM were assessed using an isokinetic dynamometer (Biodex System). During the MVC and HDSS sets, the activity of both gastrocnemius medialis (GM) and lateralis (GL) was measured using high-density surface EMG (64 channels; 8mm IED). The global level of GL and GM activity during the HDSS was estimated from the averaged, normalized (%MVC) root mean square (RMS) amplitude of the active channels (i.e., channels with RMS ≥ 70% of the maximum RMS). The average across sets was considered for the analysis. T-tests were used to compare the ROM and peak MVC before and after HDSS. Pearson correlations were applied between pre- and post-ROM measures, and global activation of GL and GM.

RESULTS: There was a statistically significant increase in ROM after stretching (PRE: 31.12 ± 6.99 degrees, POST: 36.20 ± 8.80 degrees; $P<0.0001$) with a large variability among subjects (relative ROM change from -3% to 44%). Conversely, no significant change was found for the peak MVC (PRE: 115 ± 38,31 Nm, POST: 113.33 ± 35.78 Nm; $P=0.48$). Muscle activity during the stretching was 6.92 ± 5.57 %MVC for the GL and 6.85 ± 5.50 %MVC for GM. The Pearson correlation showed a significant, negative correlation between the pre dorsiflexion ROM and normalized muscle activation for the GL ($r=-057$, $p = 0.010$) and for the GM ($r =-0.516$ $p = 0.023$).

CONCLUSION: The negative correlation between the initial ROM and the muscle activity during HDSS might be explained by an increased muscle length demand for the participants with lower muscle extensibility, who might have a higher

difficulty/discomfort during the HDSS, possibly enhancing miotatic reflexes. In future investigations, Achilles' tendon and gastrocnemius stiffness measures, with elastography, could help elucidating the mechanisms underlying the current results.

SHORT INTER-ELECTRODE DISTANCES UNDERMINE THE SENSITIVITY OF SURFACE ELECTROMYOGRAMS

VIEIRA, T., BOTTER, A., WATANABE, K., VIGOTSKY, A.D.

POLITECNICO DI TORINO

INTRODUCTION: With surface electromyography (sEMG), there is an inherent tradeoff between sensitivity and specificity. While specificity is generally acknowledged in the sEMG literature (e.g., crosstalk), only recently has the sensitivity been systematically studied (1, 2). The existence of Type II errors in surface EMG has been formalized (3), but their practical importance has not yet been documented. Specifically, how much does sensitivity affect inferences regarding muscle excitation when using bipolar sEMG?

METHODS: In this study, we used a dense array of surface electrodes to systematically assess this issue for two muscle geometries. With this array, we were able to compute bipolar EMGs for progressively greater inter-electrode distances (IEDs)—from 5 mm to 50 mm, with greater IEDs having greater spatial sensitivity—with all pairs of electrodes being centered roughly at the same skin region over biceps brachii (BB) and gastrocnemius medialis (GM) of 20 healthy subjects (7 women; age: 21–38 years; body mass: 48–88 kg; height: 158–187 cm). Using these signals, we investigated how much the onset of muscle excitation, the quality of surface EMGs (signal-to-noise ratio; SNR), and the coherence between EMG and joint moment were affected by IED. Non-parametric statistics and a Bayesian hierarchical model were used to test the hypothesis that excessively reducing IEDs limits the biomechanical and physiological validity of sEMG signals.

RESULTS: Our results revealed a significant influence of IED on the onset of muscle excitation, quality of the detected signals (SNR), and the association between EMG amplitude and joint torque. The greater the IED, the more sensitive the bipolar signal was to changes in joint torque. In contrast, IEDs shorter than 30 mm resulted in EMG descriptors of dubious validity: physiologically unplausible onset values, spuriously low SNR values, and weaker EMG-force associations.

CONCLUSION: Inter-electrode distance imposes a biophysical constraint on EMG sensitivity. Short IEDs yield EMG descriptors of dubious physiological validity, including the inflation of Type II errors. Owing to sEMG's ubiquitous use, our findings are of general biomechanical and physiological interest. We propose a potentially valid procedure for defining the most appropriate IED to help balance sensitivity and specificity in single bipolar sEMG recordings.

THE EFFECT OF FATIGUE ON THE MUSCLE ACTIVITY OF ATHLETES WITH AND WITHOUT CHRONIC ANKLE INSTABILITY DURING THE SIDE HOP TEST

NAKAJIMA, C., YOSHIDA, M., ISHIKAWA, R., YAMAMOTO, R.

NATIONAL CENTER FOR GERIATRICS AND GERONTOLOGY, HOKUSHO UNIVERSITY

INTRODUCTION: Ankle sprains often occur late in a sports competition. It is important for those returning to sports after an ankle sprain to avoid recurrent injury during fatigue. Although the side hop test is one of the most useful functional performance tests for ankle sprains, the effect of fatigue has not been considered. The purpose of this study was to investigate the effect of fatigue on the muscle activity of athletes with and without chronic ankle instability (CAI) during the side hop test.

METHODS: The study included 24 collegiate athlete volunteers. Among these athletes, there were 13 ankles with CAI (9 men [10 ankles] and 3 women [3 ankles] ; age = 19.4 ± 1.1 years, height = 167.9 ± 6.9 cm, weight = 65.9 ± 10.7 kg, Identification of Functional Ankle Instability [IdFAI] score = 18.8±4.6, mean ± SD) were matched with 13 control ankles without CAI (9 men [10 ankles] and 3 women [3 ankles] ; age = 19.7 ± 1.3 years, height = 168.8 ± 7.3 cm, weight = 65.3 ± 8.2 kg, IdFAI score = 0.5 ± 1.2) by age, height, weight, and sex. Electromyography of the tibialis anterior (TA), peroneus longus (PL), medial gastrocnemius (MG), and lateral gastrocnemius (LG) were measured during the side hop test. The measurements were recorded using surface electromyography (sEMG) and a force plate. For the side hop test, all participants were instructed to hop on one limb laterally over a distance of 30 cm. The force plate defined the lateral and medial contacts during the side hop test. The side hop test was conducted before and after applying the fatigue protocol in the Webster's study. The fatigue protocol included sprints, steps, and jumps. To identify group differences, we used four mixed-design two-way (fatigue-by-group) analysis of variances.

RESULTS: We observed the main effect of fatigue during the side hop test and found that the postfatigue time was longer than the prefatigue time (prefatigue: 7.98 ± 0.84 s vs. postfatigue: 8.37 ± 0.81 s, $p < 0.001$). Group × fatigue interactions were determined for the PL ($F = 6.93$, $p < 0.05$). The PL demonstrated higher muscle activation in the CAI than in the con-

trol following fatigue (CAI: 132.2 ± 70.4 %maximum voluntary contraction [MVC] vs. control: 80.2 ± 35.8 %MVC, $p<0.05$). A significant difference was not detected for the TA, MG, or LG.

CONCLUSION: The fatigue protocol extended the time of the side hop test. Although there was no significant difference in the side hop test time between CAI and control, the activity of the PL in the CAI increased in lateral contact. The different muscle activities are to maintain performance during the side hop test and to control inversion due to ankle instability. Therefore, the side hop test of postfatigue may be an index of returning to sports following ankle sprains.

DOES ANTERIOR CRUCIATE LIGAMENT RECONSTRUCTED INDIVIDUALS HOLD THE SAME ABILITY OF TIME TO STABILIZATION AS HEALTHY INDIVIDUALS DURING SINGLE-LEG LANDING TASKS AFTER RETURNING TO PLAY? - A PILOT STUDY

CHEN, Y.J., CHU, N., TZENG, Y.T., LEE, H.J.

NATIONAL TAIWAN NORMAL UNIVERSITY

INTRODUCTION: Anterior cruciate ligament (ACL) injury is one of the most common non-contact injuries in sports. It often happens to athletes in high-demand sports, such as football, rugby, and baseball. With ACL injuries, they might suffer from short-term mobility problems and long-term functional deficits. Even after anterior cruciate ligament reconstruction (ACLR) and returning to sports, athletes are found to have altered landing strategies in the reconstructed leg and a higher risk of re-injury due to the deficiency of dynamic postural stability. Dynamic postural control is the ability to transition from a moving action to a static state while maintaining stability. Landing tasks and the derivative index— time to stabilization (TTS) are often used as a screening method of dynamic postural control, which provides more stimulation of feedforward components in sensorimotor control and higher ground reaction force than static balancing. Thus, this study would like to discuss dynamic postural control between ACLR athletes and healthy athletes through time to stabilization (TTS) during landing tasks.

METHODS: There were eight ACLR athletes and six healthy athletes recruited in the current study. They were asked to perform two single-leg landing tasks (single-leg forward hop (SLFH) and single-leg vertical jump (SLVJ)) with a force plate (Kistler 9287, Switzerland). Each task would be conducted successfully three times. TTS was defined as the time needed from landing to static state and was collected and calculated from ground reaction force (GRF) in 3 directions (anteroposterior (AP), mediolateral (ML), and vertical (VL))

RESULTS: There was a significant difference between the two groups in MLTTS ($p=.04$) of SLVJ. There were no significant differences in other directions and SLFH. The APTTS, MLTTS, and VTTS of SLVJ in the ACLR group were 1.95±0.62, 2.05±0.62, and 1.40±0.80 seconds, respectively; and in healthy group were 1.81±0.52, 2.02±0.17, and 1.02±0.65 seconds respectively. The APTTS, MLTTS, and VTTS of SLFH in the ACLR group were 6.33±0.21, 2.10±0.59, and1.12±0.57 seconds; and in the healthy group, were 6.31±0.25, 2.24±0.80, and 1.01±0.22 seconds, respectively.

CONCLUSION: Past studies showed that ACLR athletes still had biomechanical knee deficits during vertical jumps, even when they reached horizontal functional symmetry after returning to play. This finding matches our results: the significant difference occurs only while performing SLVJ. Our results also demonstrate the same results as past studies that ML directional control is more challenging. ACLR athletes returning to sports may still have dynamic postural control deficits in ML sides during vertical performances.

THE ESTIMATION OF LEAP PERFORMANCE WITH MAINTAINING OPEN LEGS IN GRAND JETÉ FOR PROFESSIONAL BALLET DANCERS

KUROMARU, A., MARUYAMA, T.

TOKYO INSTITUTE OF TECHNOLOGY

INTRODUCTION: Ballet dancers are required to perform the same beautiful movements on both sides of the body for choreographic purposes. However, the evaluation of beautiful movement is ambiguous because there is no specific index for ballet. Therefore, we interviewed ballet instructors about the grand jeté, a dynamic and frequently used movement. The respondents answered that the most beautiful moment was during the leap and it was important to keep the legs open during the leap. Therefore, maintaining the open legs and leaping is considered to be the high performance of the grand jeté. It is considered difficult to maintain more than 50% of the leg-open posture for a short period of time during leaping. But few studies have focused on ballet movement and leg-opening posture.

In this study, we defined the performance of the leg-opening during the grand jeté as whether or not the legs were open for at least 50% of the leap time. The purpose of the study is to examine the relationship between the indexes and the differences in leg opening posture and movement.

METHODS: Fifteen professional ballet dancers (age: 26.5±3.2 years, height: 160.5±3.8 cm, weight: 47.1±3.4 kg) were subjects. The subjects were given an explanation of the study, a consent form, and a brief questionnaire. Kinematic data were obtained from three grand jeté trials on each side. The trial with the highest leaping height was selected for analysis. The mean value of the maximum leg opening angle at the time of leaping was calculated for the trials under analysis. The threshold angles for the three conditions ((1)mean+1SD, (2)mean, (3)mean-1SD) were wet based on the average values. The leg-opening maintenance rate was defined as the percentage of leg-opening retention time divided by the leaping time. In this study, leaping movements with a leg-opening maintenance rate of 50% or higher were evaluated as high performance.

RESULTS: The average leg-opening angle during leaping was 137.2±28.3°. The dancers who maintained 50% or more leg openings in the three conditions during leaping were (1)0, (2)1 dancer on the right, (3)4 dancers on the right, 1 dancer on

the left, and 6 dancers on both conditions. There was no correlation between leaping time and leg-opening maintenance rate.

CONCLUSION: The correlation results suggest that even if the leaping time is longer, it does not necessarily mean that the leg-open posture is maintained. The result of the leg-open maintenance rate suggests that the right grand jeté maintained the leg-open posture for a long period of time than the left-leaping grand jeté. The suggests that there is a left-right difference in leg-open posture performance.

RELATIONSHIPS BETWEEN SPRINT PERFORMANCE AT DIFFERENT PHASES AND SIZE AND DYNAMIC STRENGTH OF THE HIP EXTENSORS

KOBAYASHI, Y.1, MAEO, S.1,2, KINOSHITA, M.1, WU, Y.1, ONO, M.1, ARAI, H.1, SUGIYAMA, T.1, FOLLAND, J.P.2, KANEHISA, H.3, ISAKA, T.1

1 RITSUMIEKAN UNIVERSITY, JAPAN 2 LOUGHBOROUGH UNIVERSITY, UK 3 NATIONAL INSTITUTE OF FITNESS & SPORTS IN KANOYA, JAPAN

INTRODUCTION: Sprint performance is known to be strongly related to the size of the hip extensors in both males and females (Miller et al., 2021; 2022). However, less is known about how hip extensor size is related to different phases of a sprint race. Furthermore, although isometric hip extensor strength was reported to be unrelated to sprint performance (Miller et al., 2021), this could be due to a lack of specificity between a static strength measure and the dynamic nature of sprint running. Therefore, this study examined the relationships between sprint race performance, including different phases, with size and dynamic strength of the hip extensors.

METHODS: Forty-six healthy young adults (25 males and 21 females, non-obese [BMI: 18-26] or low-moderate recreational physical activity) participated. T1-weighted axial 3-T MRI scans (FOV: 200*200 mm, slice thickness & gap: 5 mm) of the hip and thigh regions were obtained for each leg to assess muscle volume of the hip extensors (the sum of the gluteus maximus and three biarticular hamstrings). Participants then performed 60-m sprint running, from which the total time (0–60 m) as well as the time of the start (0–10 m), acceleration (10–20 m) and maximum velocity (45–60 m) phases were measured using optical timing gates. One-repetition maximum (1RM) of unilateral hip extension was assessed using a hip extension machine in a standing position (from the hip 90°-flexed to 0° position with the knee kept straight). Each leg was tested for the MRI and 1RM measurements, and averaged values across legs were used for analysis. Partial correlations of sprint performance variables with hip extensor muscle volume or strength were calculated for the whole cohort controlling for sex. Coefficients were compared among the phases by William's t test.

RESULTS: Absolute and relative (to body mass) hip extensor muscle volumes were both moderately correlated with 60-m sprint time ($r = -0.525$ and -0.677). This was also true for the start ($r = -0.447$ and -0.618), acceleration ($r = -0.482$ and -0.653) and maximum velocity ($r = -0.569$ and -0.672) phases. Although the correlations tended to become stronger from the start towards maximum velocity phase for both absolute and relative muscle volume, there were no significant differences in the r values between the phases ($P \geq 0.151$). Absolute and relative hip extension 1RM were also moderately correlated with 60-m sprint time ($r = -0.479$ and -0.599), and weak–moderately correlated with the start ($r = -0.276$ and -0.407), acceleration ($r = -0.449$ and -0.579) and maximum velocity ($r = -0.527$ and -0.610) phases. The correlations of the maximum velocity phase were significantly stronger than those of the start phase for both absolute and relative 1RM ($P < 0.014$).

CONCLUSION: Both muscle size and dynamic strength of the hip extensors correlate with sprint performance, particularly for the maximum velocity phase of sprinting.

LOW CARBOHYDRATE AVAILABILITY IN ENERGY BALANCE FOR FOUR DAYS HAS NO EFFECT ON MARKERS OF BONE FORMATION BUT INCREASES MARKERS OF BONE RESORPTION IN HEALTHY EXERCISING MALES

ARETA, J.L., LANGAN-EVANS, C., MORTON, J.P., MOSQUERA, E., TAYLOR, H.L.

LIVERPOOL JOHN MOORES UNIVERSITY

INTRODUCTION: Low energy availability and low carbohydrate high-fat (LCHF) diets have both been implicated in the impairment of markers of bone metabolism. However, no study has yet evaluated the effect of LCHF-only in bone turnover markers in controlled laboratory conditions with a multi-day intervention. The aim of this study was to evaluate the effect of 4 days of LCHF compared to a protein and energy-matched, normal carbohydrate diet, in energy balance, while exercising daily. Based on current evidence, we hypothesised that blood markers of bone formation would be suppressed while markers of bone resorption would be increased by LCHF.

METHODS: Healthy trained males (n=8, 27±4 yrs, body mass 79±12 kg, VO2max 54 ± 6 ml/kg/min, body fat 16±4%) completed 4 consecutive days of a LCHF (1.5, 2.4, 3.8 g/kg/day, 12, 19, 69% total energy, from carbohydrates, fat & protein, respectively) and a normal-carbohydrate energy balance (NCEB; 7.7, 2.4 & 1.1 g/kg/day, 62, 19 & 19% total energy, from carbohydrates, fat & protein, respectively) diets in a randomised cross-over design, separated by at least 7 days wash-out

period. Diets were pre-packaged, custom-made, and provided 60 kcal/kg FFM/day energy intake. Exercise was performed daily in the laboratory on a cyclo-ergometer to expend 15 kcal/kg FFM/day, resulting in an energy availability of 45 kcal/kg FFM/day. Venous blood samples were obtained from the antecubital vein every morning in fasted conditions, including the 5th morning after 4 days dietary intervention. Body mass and body composition were measured daily by an 8-electrode phase-sensitive multifrequency BIA (SECA mBCA 515). Plasma samples were analysed for P1NP as a marker of bone formation, and β-CTX, as a marker of bone resorption. Two-way repeated measures ANOVA was performed to detect differences in means, using $p<0.05$ as a threshold of statistical significance. All data are expressed as mean ± SD.

RESULTS: Body mass did not change within groups, but it was reduced on day 5 in LCHF vs NCEB (delta 1.16 ± 0.6 kg, P=0.03), however fat free mass, fat mass, fat mass percentage and total body water remained unchanged, suggesting individuals likely remained in energy balance throughout. P1NP showed no changes (main effects: time, P=0.19; treatment, P=0.755), while β-CTX showed time (P=0.016), treatment (P=0.003) effects and an interaction (P=0.017), increasing on day 5 in LCHF (0.71 ± 0.27 µg/L) vs NCEB (0.57 ± 0.25 µg/L; P=0.017).

CONCLUSION: The main findings are that reducing carbohydrate availability during a 4-day period has no effect on markers of bone formation —which was contrary to our hypothesis— but increases markers of bone resorption. Our findings provide causal evidence that LCHF may be implicated in impairing bone metabolism or accelerating bone remodelling by increasing bone resorption relative to bone formation in the rested, fasted state.

SELF-REPORTED SYMPTOMS OF LOW ENERGY AVAILABILITY AMONG FEMALE ELITE ATHLETES AND CONTROLS

AHLGREN, M., KJÆR, J.B., LINNÉR, S., PAGELS, P., POJSKIC, P., RAGNARSSON, T., MELIN, A.K.

SPORT SCIENCE

INTRODUCTION: Severe and/or long-term low energy availability (LEA) with and without eating disorders (EDs) is the underlying cause of the syndrome Relative Energy Deficiency in Sports (REDs) with multiple health (e.g., osteoporosis) and performance consequences (e.g., increased injury risk). We aimed to investigate symptoms of LEA among athletes and recreational active people, and the associations with EDs, excessive exercise, and motivation for training and dietary behavioral changes.

METHODS: Swedish female national team athletes [Tier 4, (n=150)] from 26 sports, and recreational active women [Tier 1-2, (n=108)] 18-39 years were recruited via sport organizations and social media. Participants filled out an anonymous on-line survey comprising the LEA in Females Questionnaire (LEAF-Q) [variables; menstrual dysfunction (only scored in non-hormonal contraceptive users), gastrointestinal problems and sport injuries]. A total score > 8 was used as indicative of LEA symptoms. The Eating Disorder Examination Questionnaire (EDE-Q) (a Global score > 2.3 was used as indicative of symptoms of EDs), the Exercise Addiction Inventory (EAI), and the Motivation to Change Questionnaire (MCQ) were also included.

RESULTS: Of all participants, 47.3% had symptoms of LEA [athletes 46.7% (LEAF-Q total score 11.5 ± 3.6), and recreational active women 48.2% (LEAF-Q total score 12.1 ± 3.8)]. Participants with LEA symptoms had a lower body mass (62.9 ± 9.4 vs. 66.3 ± 10.7 kg, p=0.007) and BMI (22.3 ± 2.9 vs. 23.4 ± 3.2, p=0.003), while no differences were found in age (24.8 ± 5.3 vs. 25.3 ± 5.8 years, p=0.389) or training load (13.1 ± 5.5 vs. 13.5 ± 7.3 h/week, p=0.676) compared to those with no symptoms. Most of the participants with LEA symptoms (68.9%) did not have symptoms of EDs. However, when excluding those with symptoms of EDs, participants with LEA symptoms had higher scores of EDE-Q global (1.1 ± 0.6 vs. 0.8 ± 0.6, p=0.001), dietary restraint (1.0 ± 0.9 vs. 0.6 ± 0.8, p=0.010), shape- (1.8 ± 1.1 vs. 1.3 ± 0.9, p<0.001), and weight concern (1.2 ± 0.9 vs. 0.8 ± 0.8, p=0.006) compared to participants without LEA symptoms, as well as a higher EAI score (20.5 ± 3.6 vs. 18.7 ± 4.6, p=0.003), and a perceived reduced ability to increase energy intake (p=0.019) and lower the training load (p=0.006).

CONCLUSION: In the present study symptoms of LEA was equally frequent among elite athletes and recreational active women. Our findings confirm earlier indications that most LEA cases do not have EDs. However, our findings suggest that symptoms of LEA may still be associated with restricted eating and excessive training behaviors as well as focus on body shape and weight. Reversing LEA by increased energy intake or reduced training load or a combination is the only treatment to prevent REDs health and performance implications. Our findings therefore emphasize the need for multidisciplinary prevention and treatment strategies to ensure necessary dietary and training behavioral changes.

THE EFFECT OF A DIGITAL INTERVENTION ON EATING AND WEIGHT CONCERNS AMONG FEMALE ENDURANCE ATHLETES WITH HIGH VERSUS LOW RISK OF EATING DISORDERS

SOLSTAD, B.E., FAHRENHOLTZ, I.L., MELIN, A.K., GARTHE, I., WAALAND, M.S., TORSTVEIT, M.K.

UNIVERSITY OF AGDER

INTRODUCTION: There is a need to test the effectiveness of digital sports nutrition interventions to increase awareness of adequate energy intake to maintain optimal health and performance among female endurance athletes at risk of long-term low energy availability (LEA) and eating disorders (EDs). Current evidence suggests that female endurance athletes with symptoms of LEA, although with low risk of EDs, may have more eating and weight concerns compared to athletes without LEA symptoms. Additionally, athletes with EDs symptoms may show more resistance to improve their sport nutrition behaviour and reduce eating and weight concerns compared to athletes with no EDs symptoms. Thus, the aim of the present study was to investigate whether a 16-week digital sports nutrition intervention could reduce LEA and EDs symptoms among female endurance athletes with high versus low risk of EDs, respectively.

METHODS: In this multicentre study, female endurance athletes from Norway, Sweden, Germany, and Ireland (n=18) completed a 16-week digital sports nutrition intervention and an online survey pre- and post-intervention comprising the Eating Disorder Examination-Questionnaire (EDE-Q) and the Low Energy Availability in Females Questionnaire (LEAF-Q). Athletes 18-35 years of age with a LEAF-Q score ≥8, without chronic disease and not using hormonal contraceptives were offered the FUEL (Food and nUtrition for Endurance athletes – a Learning program) intervention with weekly sports nutrition videos. Based on a global EDE-Q cut-off score of 2.5, the participants were classified with either low (n=12) or high (n=6) risk of EDs. Group comparisons of the different questionnaire scores using a pre-post format were conducted using a Bayesian mixed factor analysis of variance with default priors and compared to the null model. To calculate the Bayes Factor (BF) for the interaction effect only inclusion probabilities for matched models were considered.

RESULTS: Changes in EDE-Q global score, EDE-Q restraint, EDE-Q eating concern, EDE-Q shape concern, and EDE-Q weight concern from pre- to post-testing did not differ between groups, as indicated by the lack of an interaction effect (BFincl < 1). Nor did changes in LEAF-Q injury, gastro-intestinal, menstrual, or total score from pre- to post-testing differ between groups (BFincl < 1).

CONCLUSION: Findings showed that participation in the FUEL intervention did not create any credible differences in LEA or EDs symptoms among female endurance athletes with high versus low risk of EDs, respectively. However, it is worth noting that the two groups showed a tendency to develop contradictory trajectories from pre- to post-intervention in relation to all LEAF-Q subscales and the EDE-Q eating concern subscale. Future research should therefore continue to further develop digital sports nutrition interventions to promote dietary behavior change in female endurance athletes who have both high and low risk of EDs.

THE EFFECT OF CREATINE MONOHYDRATE ON DUAL-ENERGY X-RAY ABSORPTIOMETRY MEASUREMENTS OF LEAN BODY MASS

DESAI, I., PANDIT, A., HAGSTROM, A.H., KAAKOUSH, N.O., SIMAR, D.

UNIVERSITY OF NEW SOUTH WALES

INTRODUCTION: Creatine supplementation (CS) is claimed to be the most safe and efficacious method to augment resistance training (RT)-based gains in lean body mass (LBM). Dual-Energy X-ray Absorptiometry (DXA) is recommended to measure changes in LBM because of its ability to differentiate between bone mineral density, fat mass, and LBM. A limitation of DXA is that LBM measures are affected by hydration status, and CS is proposed to induce water retention in muscle cells. Therefore, changes in hydration status need to be accounted for when using DXA to measure changes in LBM. Studies that have investigated the effect of CS and RT on LBM using DXA have not accounted for potential changes in hydration status due to CS. Based on the current evidence, it is not possible to discern whether changes in LBM measured via DXA result from CS-based fluid retention or muscle growth from CS and RT. We therefore investigated if DXA measurements of LBM measures were affected by potential increases in water retention from CS in healthy, untrained adults.

METHODS: Healthy, untrained adults were randomly assigned to a CS (n=17, 8 female/9 male, 28.5±8.0 years) or control (CO) (n=17, 12 female/5 male, 28.9±10.9 years) group. Both groups underwent DXA scans following an 8-hour fast with no strenuous exercise for 12 hours prior at Day 1 and Day 8. After the first scan, subjects in the CS group ingested 5 g of creatine monohydrate (CM) (True Protein; New South Wales, Australia) once a day for 7 days. Subjects in the CO group received no supplement. All subjects were instructed to maintain habitual dietary habits and physical activity levels. A two-way analysis of covariance (ANCOVA) with one between (CS and CO) and one within (time) factor was used to detect differences in means between time points. Mean change scores of each group were adjusted using participant baseline LBM as the covariate. Significance was set at $p \leq 0.05$. All data are expressed at mean ± SD.

RESULTS: There was no significant difference between groups in LBM change between Days 1 and 8. The mean difference between groups was 0.398 ± 1.953 (95% confidence interval -0.285 – 1.080, $p = 0.243$).

CONCLUSION: Ingesting 5 g of creatine daily for 7 days did not change DXA-measured lean body mass more than the control group. The lack of difference, and similar range of lean body mass change between groups, are likely due to innate lean body mass fluctuations in DXA measures that would occur regardless of creatine supplementation. In studies investigating DXA-measured lean body mass following creatine supplementation and resistance training, it is therefore likely that increases in lean body mass are due to muscular hypertrophy and not creatine supplementation-based fluid retention.

THE BONE-DERIVED COMPONENTS FROM ADULT CHICKENS PROVIDE A PROTECTIVE ACTION AGAINST IMPAIRED BONE METABOLISM IN VDRKO MICE.

NISHIURA, T., KOYAMA, N., YAMANAKA, H., MASUYAMA, R.

RITSUMEIKAN UNIVERSITY

INTRODUCTION: Post-laying hens called adult chickens are characterized by the presence of medullary bone forming a reticular structure in the endocortical domain to store calcium (Ca), which is resorbed during the formation of the eggshell to supply Ca as a major component. The remarkable bone metabolism in which frequent changes in bone formation and bone resorption occur in the laying hens body during the egg-laying cycle, it is considered that therefore medullary bone contributes to Ca homeostasis. Normal Ca homeostasis and bone metabolism are primary requirements to maintain healthy bones in all generations, and the development of higher bone mass by early adulthood ensures lifelong athletic

function. In this study, we tested whether the oral administration of bone-derived components from adult chickens to animals could improve Ca and bone metabolism.

METHODS: The effects of bone-derived components from adult chickens on bone metabolism were investigated in systemic vitamin D (VD) receptor knockout mice (VDRKO), in which VD-dependent Ca absorption and homeostasis are disrupted. Meat samples were prepared from adult chickens or young chickens with no egg-laying experience by pressing meat parts including bones, heat-sterilizing, and freeze-drying. The test diets (adult chicken bone-containing diet and young chicken bone-containing diet) were prepared by replacing 25% of the diet weight with each meat sample. A control diet was used in which the Ca content was matched to that of the adult chicken bone-containing diet. Wild-type mice (WT) and VDRKO were fed one of each diet for 4 weeks from 5 weeks of age.

RESULTS: Hypocalcemia, characteristic of VDRKO, was observed only in the young chicken bone-containing group (young chicken group) and the control diet group and improved to the same level as WT in the adult chicken bone-containing diet group (adult chicken group). This result contributed to the improvement in blood parathyroid hormone levels in the VDRKO, blood PTH levels are decreased within normal range in the adult chicken group whereas severe hyperparathyroidism appeared in the young chicken and control diet groups. The bone phenotype was affected by calcium homeostasis, bone strength was decreased in the VDRKO young chicken and control diet groups, but those values of the adult chicken group recovered to the same level as WT. In addition, micro-CT analysis of the femurs showed a significant increase in cortical bone mineral density in VDRKO adult chicken group compared to the control diet group. The impaired apparent Ca absorption in VDRKO was partly recovered by the dietary treatment, the adult chicken group significantly increased only in female mice.

CONCLUSION: These results suggest that bone-derived components from adult chickens contain two types of VD-independent factors that contribute to bone health, one that improves Ca absorption in the intestinal tract and the other that has a direct improving effect on bone.

THE EFFECTS OF ENERGY, NUTRITIONAL INTAKE AND AGE AT MENARCHE ON BONE MINERAL DENSITY IN RHYTHMIC GYMNASTS

JUNNA, M.1, TOSHIHARU, T.2, TSUKAHARA, Y.3, SUGURU, T.2

<1> WASEDA UNIVERSITY, <2> WASEDA UNIVERSITY, <3> TOKYO WOMENS COLLEGE OF PHYSICAL EDUCATION

INTRODUCTION: Rhythmic gymnasts manage their diet and daily training to maintain their body shape. As a result, they are prone to eating disorders, inadequate energy intake, and menstrual dysfunction. Intense training from an early age also increases the likelihood of delayed menstruation and primary amenorrhea. Chronic inadequate energy intake and menstrual dysfunction negatively affect bone mineral density (BMD). This study aimed to examine the associations between energy, nutritional intake and age at menarche and BMD.

METHODS: Thirty-eight female rhythmic gymnasts (mean age = 19.3 ± 1.1 yrs) who have been practicing rhythmic gymnastics since before the age of 10 years participated in this study. We used a questionnaire to obtain responses on the history of rhythmic gymnastics competitions and chronological age. Nutritional intake was assessed using a food frequency questionnaire (FFQ). All participants underwent dual-energy X-ray absorptiometry (DXA) to assess their total body and lumbar spine bone mineral content (BMC), BMD and Z-score. Independent t-tests were used to evaluate the difference between delayed menstruation and BMC as well as BMD. Pearsons correlation analysis, Spearman's rank correlation coefficient and multiple regression analysis were performed to examine the relationship between nutritional intake and BMD as well as BMC. P-value < 0.05 was considered statistically significant.

RESULTS: The average energy intake among the rhythmic gymnasts (1,673 ± 34 kcal/day) was less than activity level III (2,300 kcal/day) of the Japanese Dietary Reference Intakes. The BMD of each gymnast was acceptable and did not present as a Z-score of below -1. After adjusting for energy intake using the residual methods, dietary fibre correlated with lumbar spine BMD ($r = 0.365$, $p = 0.024$) and lumbar spine BMC ($r = 0.409$, $p = 0.011$), while vitamin C correlated with lumbar spine BMC ($r = 0.327$, $p = 0.045$). The mean age at menarche was 15.4 ± 1.4 years. There were no differences in the total body and lumbar spine BMD or BMC of athletes with menarche before or after age 15 years of age. Regression analysis showed that none of the predictors of BMD were significant. Only adjusting for energy intake dietary fibre ($p = 0.035$) was predictive of lumbar spine BMC.

CONCLUSION: Delayed onset of the first menstruation was observed in approximately 70% of all rhythmic gymnasts but there were no significant differences in the BMD or BMC. BMD was high despite deficient energy intake. The results suggest that competition-specific movements and training before the adolescent performed by rhythmic gymnastics may contribute to a high BMD. Further research studies with a larger number of participants and detailed investigations into menstrual function, diets and bone quality are warranted.

EFFECTS OF INTERMITTENT FASTING AND EXERCISE ON UCP1 SIGNALING PATHWAY IN HIGH FAT DIET-INDUCED OBESE MICE

CHAEEUN, C., EUNHEE, C., SEWON, L.

INCHEON NATIONAL UNIVERSITY

INTRODUCTION: Obesity has been a worldwide health problem over the past decades. In order to prevent and reduce obesity, it is necessary to reduce caloric intake while increasing energy expenditure. Previous studies have reported that uncoupling protein 1 (UCP1) activation promotes energy expenditure through browning of white adipose tissue (WAT).

Increased energy consumption through the promotion of UCP1 expression in brown adipose tissue (BAT) and browning of WAT, can be potential therapeutic targets to overcome obesity and metabolic diseases. Therefore, it is important to investigate interventions that can stimulate UCP1 and UCP1-related signaling mechanisms. The purpose of this study was to investigate whether intermittent fasting and swimming exercise activate UCP1-related signaling pathways and which intervention is more effective on metabolic parameters.

METHODS: Six-week-old male wild-type C57 BL/6 J mice were used and randomly assigned to the following 4 groups: the control group (CON, n=10), the high-fat diet group (HFD, n=10), the high-fat diet + intermittent fasting group (HFD+IF, n=8), and the high-fat diet + swimming exercise group (HFD+SEG, n=8). Intermittent fasting was treated 24 h fasting and 48 h feeding cycle, and swimming exercise was treated for 90 minutes a day, 5 times a week for 8 weeks.

RESULTS: After 8 weeks of treatment, the intermittent fasting and swimming exercise significantly improved body weight, triglycerides, insulin, and HOMA-IR. In the soleus muscle, AMPKα, PGC-1α, and FNDC5 protein levels were no significant difference between groups. However, in the gastrocnemius muscle, PGC1a and AMPKa protein levels were increased by swimming exercise. In contrast, intermittent fasting did not alter the levels of AMPKα, PGC-1α, and FNDC5 protein in skeletal muscles. In the BAT, the UCP1 protein level was increased by intermittent fasting and swimming exercise. In the subcutaneous fat, only intermittent fasting increased UCP1, but there was no significant difference between groups in UCP1 protein level in epididymal fat.

CONCLUSION: Intermittent fasting and swimming exercise ameliorated HFD-induced metabolic dysfunction. In addition, both intermittent fasting and swimming exercise-induced browning through increased UCP1 expression. However, intermittent fasting increases UCP1 expression independently of signaling mechanisms expressed in skeletal muscle.

INTERACTIVE EFFECTS OF FEEDING STATUS AND EXERCISE INTENSITY ON POSTPRANDIAL GLYCAEMIC CONTROL AND EATING BEHAVIOUR IN INDIVIDUALS WITH CENTRAL OVERWEIGHT/OBESITY

CHEN, Y.C.1, HONG, J.Y.1, YANG, S.W.1, LI, Y.J.1, METCALFE, R.S.2, WANG, H.S.1

DEPARTMENT OF PHYSICAL EDUCATION AND SPORT SCIENCES, NATIONAL TAIWAN NORMAL UNIVERSITY, TAIWAN1 & APPLIED SPORT, TECHNOLOGY, EXERCISE AND MEDICINE RESEARCH CENTRE, SWANSEA UNIVERSITY, UK2

INTRODUCTION: Pre-exercise feeding and exercise intensity have been shown to independently affect postprandial glycaemic control and energy intake. However, it is unclear whether there is an interactive effect of these two elements on post-exercise postprandial glycaemic control and eating behaviour in adults with overweight and obesity.

METHODS: Twelve (10 men and 2 postmenopausal women) centrally overweight/obese participants (mean ± SD: Age: 40 ± 7 years; waist circumference: 92 ± 9 cm) exercised on a treadmill for 4 km under either fasted or fed (5.5 kcal energy per kilogram body mass; 77% carbohydrate, 16% fat & 8% protein) conditions at either low- (50% V̇O2max) or high-intensity (70% V̇O2max) (FED-LOW, FED-HIGH, FAST-LOW & FAST-HIGH) in a randomised crossover design. After the completion of exercise, a 2-h 75-g oral glucose tolerance test (OGTT) was conducted immediately, followed by a 30-min lunch meal to assess ad libitum energy intake. Venous blood samples were collected at regular intervals throughout each trial to determine differences in glucose and insulin concentrations.

RESULTS: Exercise intensity (% of V̇O2max) during the 4 trials was 48 ± 4% during FAST-LOW, 51 ± 5% during FED-LOW, 71 ± 6% during FAST-HIGH and 71 ± 5% during FED-HIGH. There were differences in the total glucose area under curves (tAUC) during the OGTTs ($p = 0.003$), with both FAST-LOW (21612, 95% CI [19688, 23537] mg/150 min/dL) and FAST-HIGH (21940, 95% CI [20875, 23005] mg/150 min/dL) being higher than FED-LOW (19311, 95% CI [18337, 20285] mg/150 min/dL; both, $p < 0.05$) and FAST-HIGH was greater than FED-HIGH (21940, 95% CI [20875, 23005] versus 19598, 95% CI [18603, 20594] mg/150 min/dL, $p = 0.037$). No differences were found for insulin tAUCs between trials ($p = 0.663$). There was also no difference in ad libitum energy intake during lunch between 4 trials following OGTT (713 ± 441 kcal in FAST-LOW, 708 ± 449 kcal in FED-LOW, 746 ± 454 kcal in FAST-HIGH and 726 ± 450 kcal in FED-HIGH, $p = 0.996$).

CONCLUSION: Exercise in the fed state reduces subsequent postprandial glucose concentrations compared to exercise in the fasted state, irrespective of exercise intensity. Neither feeding status nor exercise intensity altered ad libitum energy intake during a post-exercise lunchtime meal.

THE EFFECTS OF DIET AND SELENIUM-ZINC CO-SUPPLEMENTATION ON BODY COMPOSITION AND EXERCISE PERFORMANCE IN OVERWEIGHT-OBESE INDIVIDUALS

GIANNAKI, C., ZAVROS, A., APHAMIS, G., ROUPA, Z., BOGDANIS, C.G., ANDREOU, E.

UNIVERSITY OF NICOSIA

INTRODUCTION: Zinc and selenium are trace elements that play a major role in many biological processes in the human body (2, 5). Obese people appear to have lower zinc and selenium plasma levels than people with normal weight (3). However, the effect of zinc and selenium on body composition is still controversial (6). Allthough it has been demonstrated that low zinc levels negatively affect physical performance (4), it is still unknown whether zinc supplementation could positively affect exercise performance in this population. This randomized, double-blind, placebo-controlled trial aimed to examine the effects of a hypocaloric diet and selenium-zinc co-supplementation on body composition and exercise performance in overweight-obese individuals.

METHODS: Twenty-eight overweight-obese participants (mean BMI: 29.4 ± 4.7) were randomly 1:1 allocated to the supplementation group (n= 14, 9 females, 31.1± 5.5 yrs) and the placebo group (n= 14, 6 females, 32.1 ± 4.8 yrs). The partici-

pants received supplements of zinc and selenium or placebo tablets for eight weeks. The participants of both groups followed a hypocaloric diet during the intervention. Body composition, cardiorespiratory fitness (VO2max), and functional capacity (sit-to-stand tests, timed-up and go-TUG test, handgrip strength) were assessed before and after the intervention period.

RESULTS: Body fat was reduced, but cardiorespiratory fitness did not change over the intervention. However, some functional capacity tests improved similarly in both groups over the eight-week intervention period ($p < 0.05$). In contrast, a time x group interaction was found in the performance of the TUG test ($p = 0.010$), with the supplementation group improving more.

CONCLUSION: An eight-week zinc and selenium co-supplementation did not affect body composition and exercise performance in overweight-obese individuals. On the other hand, the supplements were effective in terms of improving performance in the TUG test.

INFLUENCE OF TYPE 2 DIABETES MELLITUS DURATION ON THE EFFECTIVENESS OF A LIFESTYLE INTERVENTION: RESULTS FROM THE INTENSITY STUDY

RIOUX, B.V., THOMSON, A.M., HRUBENIUK, T.J., BOUCHARD, D.R., SÉNÉCHAL, M.

UNIVERSITY OF NEW BRUNSWICK

INTRODUCTION: It is well-established that type 2 diabetes mellitus (T2DM) duration has an impact on the management of the disease. In fact, studies on T2DM reversal suggest that a shorter duration of T2DM presence increases the likelihood of achieving remission. However, it is unclear whether the duration of time an individual has lived with T2DM impacts the response to an exercise intervention. Therefore, the purpose of this study was twofold: 1) to compare the changes in body composition between individuals with shorter and longer durations of T2DM who participated in 28 weeks of aerobic exercise, and 2) to determine whether these changes in body composition are associated with improved glycemia according to T2DM duration.

METHODS: This secondary analysis included thirty-four adults (>19 years old) with T2DM who took part in 28 weeks of aerobic exercise training. Participants were categorized into two groups using pre-established cut-points: 1) short duration T2DM (<5 years) or 2) long duration T2DM (≥5 years). Each group exercised according to the national recommendation of 150 minutes per week of moderate-to-vigorous aerobic exercise (4.5 to 6.0 metabolic equivalents (METs)). Glycemia was measured by glycated hemoglobin (HbA1c), body composition by BodPod, and cardiorespiratory fitness by peak oxygen consumption (VO2peak). All measurements were performed at baseline, 16 weeks and 28 weeks.

RESULTS: Following the completion of the trial, participants in the short duration T2DM group experienced a significant reduction in waist circumference ($F(2) = 8.206$, $p = 0.01$) and an increase in relative VO2peak ($F(2) = 4.094$, $p = 0.05$), while those with a longer duration of T2DM decreased fat mass (kg) ($F(2) = 5.571$, $p = 0.01$) and body fat percentage ($F(2) = 9.243$, $p < 0.01$), and increased fat-free mass ($F(2) = 3.641$, $p < 0.05$). A significant change was observed in HbA1c throughout the 28 weeks of exercise in the short duration T2DM group ($F(2) = 4.643$, $p = 0.04$), but not in the long duration T2DM group. Interestingly, no significant correlations were found between changes in HbA1c and changes in body composition in the short duration T2DM group, but the changes in weight ($r = 0.50$, $p = 0.02$), body mass index ($r = 0.49$, $p = 0.02$), waist circumference ($r = 0.50$, $p = 0.02$), fat mass ($r = 0.54$, $p = 0.02$) and body fat percentage ($r = 0.50$, $p = 0.02$) were significantly associated with the change in HbA1c in those with a longer duration of T2DM.

CONCLUSION: Our data demonstrate that those who have lived with T2DM for a longer duration experienced a greater improvement in body composition, which was significantly associated with the change in glycemia in this group. The results of this study suggest that the duration of T2DM presence affects the response to aerobic exercise.

THE EFFECT OF 10-DAYS OF HOT WATER IMMERSION ON CENTRAL HAEMODYNAMICS, BLOOD PRESSURE AND VASCULAR FUNCTION IN INDIVIDUALS WITH TYPE 2 DIABETES MELLITUS

PICCOLO, D., JAMES, T., CORBETT, J., CUMMINGS, M., ALLARD, S., EGLIN, C., BELCHER, H., TIPTON, M., PERISSIOU, M., SAYNOR, Z., SHEPHERD, A.

UNIVERSITY OF PORTSMOUTH

INTRODUCTION: Type 2 diabetes mellitus (T2DM) is characterised by progressive insulin resistance, hyperglycaemia and endothelial dysfunction, leading to increased risk of cardiovascular disease. Previous research in healthy adults has suggested that passive heat therapy may provide an alternative to exercise ('exercise mimetic') that can improve vascular health [1], but data are lacking from individuals with T2DM.

METHODS: Fourteen individuals completed a pre-post experimental study whereby central haemodynamics, blood pressure and vascular function were assessed pre- and post- 8-10 x 1 h hot water immersions (HWIs) (40 °C water) undertaken within a 14 day period. During HWIs, body position was adjusted to clamp rectal temperature at 38.5-39.0 °C. Central haemodynamics were assessed via stroke volume index (SVi), cardiac index (Qi), and resting heart rate (RHR) using thoracic impedance cardiography. Resting systolic blood pressure (SBP) and diastolic blood pressure (DBP) were recorded, and brachial flow mediated dilation (FMD) was assessed via ultrasound. Microvascular endothelial function was assessed via transdermal delivery of acetylcholine (Ach) and insulin using iontophoresis. Resting metabolic rate (RMR) was measured using a metabolic cart. Results (mean [SD]) were analysed using a paired t-test or Wilcoxon Signed Rank test for non-parametric data (significance $p < 0.05$) with effect sizes by Cohen's d or Rosenthal's r (non-parametric data).

RESULTS: SVi (pre: 54.6 (13.3) mL·m2, post: 49.4 (11.3) mL·m2, $p<0.02$, d=0.73), RHR (pre: 67 (12) beats.min-1, post: 64 (11) beats.min-1, $p<0.01$, d=0.83) and Qi (pre: 3.6 (0.7) L·min-1·m2, post: 3.0 (0.5) L·min-1·m2, $p<0.01$, d=0.88) were all significantly reduced following 10-days HWI intervention. SBP was also significantly reduced (pre: 136 (19) mmHg, post: 127 (15) mmHg, p=0.03, d=0.63), whereas DBP was unchanged (pre: 81 (11) mmHg, post: 80 (10) mmHg, p=0.56, d=0.15). Neither brachial FMD measures of macrovascular endothelial function (pre: 2.88 (1.81) %, post: 2.45 (1.56) %, p=0.43, d=0.22) nor microvascular function on the forearm were changed (Ach max, pre: 0.40 (0.25) CVC (flux.mmHg-1), post: 0.49 (0.50) CVC (flux.mmHg-1), p=0.63, r=-.09; Ach AUC, pre: 1.52 (1.60) CVC (flux.mmHg-1), post: 2.06 (2.77) CVC (flux.mmHg-1), p=0.63, r=-.09; insulin (insulin max, pre: 0.36 (0.56) CVC (flux.mmHg-1), post: 0.25 (0.33) CVC (flux.mmHg-1), p=0.51, r=-.13; insulin AUC, pre: 1.11 (2.10) CVC (flux.mmHg-1), post: 0.81 (0.99) CVC (flux.mmHg-1), p=0.86, r=-.03). RMR was significantly reduced (pre: 1987 (512) kcal·day-1, post: 1855 (379) kcal·day-1, p=0.045, d=0.59).

CONCLUSION: The present study demonstrates that 10 days HWI can improve SBP and cardiac efficiency in individuals with T2DM but does not improve endothelial function.

THE INDEPENDENT AND COMBINED ASSOCIATIONS OF CARDIORESPIRATORY FITNESS AND BODY MASS INDEX WITH METABOLIC SYNDROME IN MIDDLE-AGED JAPANESE ADULTS: KZS STUDY

ZHAI, X.1, KUROSAWA, S.1, SAWADA, S.1, KORIYAMA, S.1, DIMITROFF, S.1, TSUNEDA, U.1, SHIMIZU, S.1

WASEDA UNIVERSITY

INTRODUCTION: Despite previous studies suggesting independent associations of poor cardiorespiratory fitness (CRF) and high body mass index (BMI) with the development of metabolic Syndrome (MetS), the combined impact of CRF and BMI on MetS taking into account health-related behaviors has not been thoroughly examined in middle-aged Japanese adults. This study aims to investigate the independent and combined association of CRF and BMI with MetS in middle-aged Japanese adults.

METHODS: A cross-sectional study was conducted using observational data from the KZS study, a 6-month randomized controlled trial in Japan that investigated the effects of structured exercise training on Japanese adults. A total of 417 participants aged 39–64 (mean age: 50.3±6.4) were included in this study. CRF was estimated at baseline using a cycle ergometer, and participants were divided into three categories: high (upper 40%), moderate (next upper 40%), and low CRF (lower 20%). Height and weight, used to calculate BMI, were measured using a stadiometer and a standard scale. Participants were grouped into two categories: obese (BMI ≥ 30) and non-obese (BMI < 30). According to the IDF and AHA/NHLBI criteria, MetS was diagnosed by evaluating the presence of three of the following five risk factors: waist circumference ≥ 85 cm in men or ≥ 90 cm in women, elevated triglycerides ≥ 150 mg/dL, reduced HDL-C < 40 mg/dL in men or < 50 mg/dL in women, elevated systolic blood pressure ≥ 130 mm Hg and/or diastolic blood pressure ≥ 85 mm Hg, and elevated fasting glucose ≥ 100 mg/dL. Binary logistic regression models were used to estimate the odds ratios (ORs) and 95% confidence intervals (95% CIs) with MetS as the dependent variable and CRF, BMI, or the combination of CRF and BMI categories (3*2 groups) as the independent variables. The models were adjusted for age, gender, smoking, drinking, physical activity, sedentary behavior, sleeping, and educational levels.

RESULTS: Results showed that 221(53.0%) of participants had MetS. Compared to those with high CRF, those with moderate and low CRF had adjusted ORs (95%CI) for MetS of 1.62 (1.01–2.59) and 2.27 (1.27–4.06), respectively. The adjusted OR (95%CI) for MetS in obese participants was 2.12 (1.25–3.58) compared to non-obese participants. Furthermore, using non-obese participants with high CRF as the reference, the ORs (95%CI) for MetS in non-obese participants with moderate CRF,

non-obese participants with low CRF, obese participants with high CRF, obese participants with moderate CRF, obese participants with low CRF were 1.53 (0.90-2.59), 2.12 (1.1-4.09), 2.45 (0.77-7.75), 2.63 (1.28-5.39), and 3.86 (1.45-10.29), respectively.

CONCLUSION: Significant independent and combined associations of CRF and BMI with MetS were observed in this study. Therefore, it is important to prioritize targeted and tailored intervention programs to lower BMI and promote CRF in order to prevent adverse short and long-term health outcomes.

EXERCISE METABOLISM IN INCREASED PROLACTINEMIA: A CASE STUDY

EMHOFF, C., DUSSAUGE, M., MESSONNIER, L.

UNIVERSITÉ SAVOIE MONT BLANC

INTRODUCTION: Prolactin (PRL) is a peptide hormone that is best known for its role in lactation in mammals. PRL has many other functions in regulating the reproductive system, nervous system and metabolism. In humans, normal circulating PRL is <25 ng/mL, whereas hyperprolactinemia is characterised by levels >100 ng/mL and has been linked to insulin resistance, glucose intolerance, and a predisposition to the development of metabolic syndrome. However, nonpregnant premenopausal women with PRL levels between 25-100 ng/mL are rarely studied. This range has recently been proposed to be a homeostatic functionally increased transient prolactinemia (HomeoFIT-PRL) [1]. We identified a HomeoFIT-PRL patient as a case study to perform metabolic testing during rest and exercise in fasted and fed states. We hypothesised that compared to women with normal PRL levels, the HomeoFIT-PRL patient would exhibit high blood lactate, an intermediate metabolite that is strongly associated with diabetes risk in adults [2].

METHODS: We measured blood lactate and glucose concentrations in one nonpregnant 22 year-old female HomeoFIT-PRL patient (PRL of 42-90 ng/mL in the past six months) during an incremental exercise test on a cycle ergometer at 9:00 in the morning in overnight fasted (12 h) and fed states. The fed state involved the patient consuming a mixed meal of 450 kcal (60% CHO, 28% fat, 12% protein) following an overnight fast. Exercise testing began 1 h following completion of the meal. The patient also completed after an overnight fast an oral glucose tolerance test (OGTT), during which glucose and lactate were measured every 15 minutes for 2 h after ingesting a 75 g CHO beverage. A control group of age- and fitness-matched women with PRL <25 ng/mL underwent the same testing to compare with the patient.

RESULTS: During incremental exercise, blood lactate in the HomeoFIT-PRL patient remained low in the fasted state (<2.0 mM) up to ~65% VO2max, after which lactate rapidly increased to >4.0mM. Postprandial lactate decreased from 3.0 mM at pre-exercise to 1.7 mM at ~55% of VO2max, after which lactate increased and remained higher than the fasted state exercise test. During the OGTT, glucose peaked (188 mg/dL) at 30 min and returned to near basal levels (100 mg/dL) by 75 min, while lactate peaked (3.9 mM) at 60 min and remained slightly elevated (1.5 mM) by 120 min.

CONCLUSION: The HomeoFIT-PRL patient in this case study exhibited metabolic responses at rest and during exercise in fasted and fed states that may suggest altered lactate metabolism. Further studies investigating the metabolic profile of HomeoFIT-PRL are warranted in this patient population.

DEVELOPMENT OF THE KOREAN FIREFIGHTER PERFORMANCE BATTERY: JOB-RELATED PHYSICAL FITNESS ASSESSMENT

SEO, D.I., LEE, H.J., KIM, J.B.

DONGGUK UNIVERSITY

INTRODUCTION: The Candidate Physical Ability Test (CPAT) is used in North America to assess firefighters fitness, but it is difficult to implement in Korean fire stations due to space and cost constraints. This study aims to develop and validate an alternative evaluation method called the Korean Firefighters Physical Ability Test (KFPB). The study found that the KFPB is a valid and reliable tool for assessing cardiorespiratory endurance, muscular strength, and muscular endurance in firefighters. The KFPBs evaluation criteria were classified into quartiles to increase its utilization, and it is an appropriate fitness evaluation tool suitable for Korean firefighters who require a high level of physical fitness.

METHODS: This study was conducted in three parts to verify the validity and reliability of the Korean Firefighters Physical Ability Test (KFPB) and to determine its evaluation criteria. Part 1 involved 20 male firefighters performing both the KFPB and CPAT, with oxygen consumption, heart rate, completion time, and perceived test intensity measured. Part 2 involved 90 novice firefighters (85 male and 5 female) performing the KFPB test-retest with a wash-out period, and completion time was recorded. Part 3 involved 94 novice firefighters (89 male and 5 female) performing the KFPB, and completion time was recorded to determine evaluation criteria.

RESULTS: In Part 1, positive correlations were observed between completion time, heart rate, oxygen consumption, and RPE indicators ($p < .05$). In addition, all eight sections of the CPAT and KFPB had significantly positive correlations (completion time, $r = .322–.664$, $p < .05$; heart rate, $r = .766–.880$, $p < .05$; oxygen consumption, $r = .373–.799$, $p < .05$). In part 2, intra-class correlation indicates an excellent level of 0.91, which satisfies the required level for reliability verification. In Part

3, the completion time, which was classified into quartiles of the KFPB was 441 – 497 seconds for the first grade, 498 – 521 seconds for the second grade, 522 – 599 seconds for the third grade, and 560 –751 seconds for the fourth grade.

CONCLUSION: This study found that the KFPB is a valid and reliable tool for evaluating the physical fitness of firefighters, with strong correlations to the CPAT and an excellent level of test-retest reliability. Evaluation criteria were presented in quartiles. Overall, the KFPB is a suitable fitness assessment tool for firefighters, addressing the limitations of the CPAT, and may help Korean firefighters maintain high fitness levels and perform firefighting activities safely and efficiently.

CHARACTERISTICS OF VISCERAL FAT AREA AND BLOOD PROPERTIES OF JAPANESE OVERWEIGHT MALE UNIVERSITY ATHLETES

TOMOMI, T.

JOSAI INTERNATIONAL UNIVERSITY

INTRODUCTION: Athletes whose weight affects their performance, eat and train to gain weight. In this case, because the body mass index (BMI) is calculated based on height and weight, many athletes with a BMI ≥25 kg/m2 are classified as overweight. Previous studies have stated that large-sized athletes are associated with body fat percentage (BF%) and risk factors for developing cardiovascular disease. Additionally, we have reported that athletes in various sports with higher BMI also have higher visceral fat area (VFA). However, VFA and blood characteristics of male university athletes with a BMI ≥25 kg/m2 have not been characterized.

The purpose of this study was to clarify the characteristics of VFA and blood properties of Japanese overweight male university athletes.

METHODS: The participants were 39 male university athletes with BMI ≥25.0 kg/m2 (Overweight-Athletes group). The control groups consisted 141 male university athletes with BMI between 18.5 kg/m2 and 25.0 kg/m2 (Normal-Athletes group) and 16 healthy male university students (Non-athletes group).

Anthropometry and blood sampling were performed in the early morning after an overnight fast. The VFA and waist circumference were measured using abdominal bioelectrical impedance analysis (Panasonic, EW-FA90).

Blood parameters were total protein, albumin, aspartate aminotransferase, alanine aminotransferase (ALT), γ-Glutamyl Transpeptidase (γ-GTP), Total-cholesterol (T-cho), low-density lipoprotein cholesterol (LDL-cho), high-density lipoprotein cholesterol (HDL-cho), triglycerides (TG), blood urea nitrogen, creatinine, urinary acid, glucose, and hemoglobin A1c.

RESULTS: VFA was 79.5 cm2 (65.8–111.3 cm2) in the Overweight- Athletes group, which was more than twice as high as that in the Normal-Athletes group ($p < 0.0001$). The percentage of participants with VFA ≥ 100 cm2 in the Overweight-Athletes group was 17/39 (43.6%).

In the Overweight- Athletes group, positive correlations were found between VFA and ALT ($r = 0.408$, $p < 0.01$), γ-GTP ($r = 0.544$, $p < 0.0001$), LDL-cho ($r = 0.330$, $p < 0.05$), and TG ($r = 0.436$, $p < 0.01$).

Within the Overweight-Athletes group, ALT, γ-GTP, and HDL-cho between the Overweight- Athletes group with VFA ≥ 100cm2 and those with VFA < 100cm2. The Overweight- Athletes group with VFA ≥ 100cm2 had higher AST ($p < 0.0001$) and γ-GTP ($p < 0.01$) and lower HDL-cho ($p < 0.05$) than those with VFA < 100 cm2.

CONCLUSION: It is suggested that Japanese overweight male university athletes had a VFA more than twice as high as than that of the normal athletes, and athletes with higher VFA also had higher markers of liver function and lipid metabolism.

ACTOVEGIN IN A NEW PERSPECTIVE – THE EFFECTS ON AEROBIC PERFORMANCE

HASSØ, R.1, LINDTOFTE, S.1, KOSIK, B.2, BERGDAHL, A.2, LARSEN, S.1

1XLAB, DEPARTMENT OF BIOMEDICAL SCIENCES, FACULTY OF HEALTH SCIENCES, UNIVERSITY OF COPENHAGEN, DENMARK, 2DEPARTMENT OF HEALTH, KINESEOLOGY & APPLIED PHYSIOLOGY, CONCORDIA UNIVERSITY, MONTREAL, CANADA

INTRODUCTION: Actovegin (Act) is a deproteinized hemodialysate from calf-blood containing more than 200 low-weight molecules. The potential ergogenic effects of Act have previously been investigated, with studies concluding Act has no effects regarding aerobic performance [1]. However, these findings were all found in relation to acute injections with Act. Evidence exists that Act shows enhancing effects on mitochondrial respiration [2] and may alter erythrocyte function as well [3]. Therefore, the aim of this on-going study is to investigate whether Act shows performance enhancing effects with chronic treatment, and whether this effect is additive with aerobic exercise training.

METHODS: A total of 40 healthy adult male mice were included in this study. The mice were divided into 4 groups; Act treated (A), saline treated (C), trained Act treated (AT) and trained saline treated (CT). All mice were treated for 14 days, with injections of either 0.1 ml Act (10mg/ml) or saline every other day. The training intervention consisted of a HIIT protocol, performed every other day by the trained groups (5 bouts of 1 min. at 85-95% of maximal running speed and 2 min. active recovery at 60-65% of maximal running speed between intervals). All mice completed a maximal aerobic performance test before and after the intervention period. High resolution respirometry (Oroboros, O2K) was used to assess skeletal muscle (V. Lateralis) mitochondrial respiration after the 14 day intervention. One-way ANOVA, Two-way ANOVA and Tukey's Multiple comparisons test were used for the statistical analysis, with an alpha-level of 0.05.

RESULTS: The most important novel finding in this study is that chronic treatment with Act has a performance enhancing effect. Both the CT and the AT group improved their aerobic exercise capacity after the 14 day intervention ($p < 0.01$ for

both groups). However, the percentage increase in performance was significantly higher in the AT group (32 %) compared to the CT group (17 %) ($p < 0.01$), showing an additive ergogenic effect of Act with training. Mitochondrial complex I + II linked respiration was significantly increased in the AT group compared to C ($p < 0.05$), showing additive effects of Act treatment with training on mitochondrial function. Neither Act treatment nor training alone showed significant improvements of mitochondrial function.

CONCLUSION: This is the first study showing that Act has a performance enhancing effect. Hence these findings are in rodents it would be highly relevant to investigate in human. Act remains permitted by WADA and other antidoping agencies, but we advocate these institutions to once again consider the status of Act.

PHYSIOLOGICAL AND METABOLIC ADAPTATIONS TO AN INTENSIVE, MULTI-DAY MOUNTAINEERING EXPERIENCE FOR ACTIVE POSTMENOPAUSAL WOMEN: THE SARDINIA SELVAGGIO BLU WILD TREK

MELONI, M.

UNIVERSITY OF SASSARI

INTRODUCTION: Outdoor activities are increasingly being recommended as ideal strategies for preventing and contrasting age-related losses in physical capacities, which in postmenopausal women are worsened by the decline in estrogen levels. In this framework, we proposed to evaluate in this population the effects of wild trekking by examining the functional and metabolic adaptations to an intensive, physically, and technically demanding 5-day trek.

METHODS: Six healthy, active postmenopausal women in their sixth decade of life (range 51-60 years old; median body mass index 25) participated in the study. Six men of comparable age, training status and mountaineering skills were also enrolled for gender-based comparisons. The participants traversed the Selvaggio Blu wild trek (Sardinia, Italy) completing a total of 56 kilometers, for an overall height differential of 14301 meters. During all five-days trek, subjects were supervised by two alpine guides. Changes in body composition, cardiorespiratory fitness, and metabolic patterns of energy expenditure were evaluated before and after the intervention.

RESULTS: Total energy expenditure during the trek was significantly higher ($p=0.03$) in women (12.88±3.37 kcal/hour/kg) than men (9.27±0.89 kcal/hour/kg). Extracellular (ECW) and intracellular water (ICW) increased significantly following the trek only in women (ECW: -3.5%; $p=0.02$; ICW: +3.3%; $p=0.002$). The same applied to fat-free mass (+4.3%; $p=0.012$), fat mass (-15.1%; $p=0.012$), skeletal muscle mass (+7.3%; $p=0.013$), and appendicular muscle mass (+5.7%; $p=0.005$. VO2/kg (+12%; $p=0.013$) and fat oxidation (at 100 W: +14.35%; $p=0.024$; at 120 W: +26.26%; $p=0.002$) were found increased in a significant manner only in women.

CONCLUSION: In post-menopausal women, a 5-day, intensive and physically/technically demanding outdoor trekking activity led to significant and potentially relevant changes in cardiorespiratory fitness, body-composition, energy balance and metabolism that are generally attained following quite longer periods of training. The significant changes in cellular hydration indicate that short but intense workouts specifically targeting the musculoskeletal system, such as the trekking experience here administered, have the potential to act as anabolic primers. However, due to the lack of effect among the male participants, who exercised at a lower relative intensity, attention should be put in adequately engaging participants according to their technical skills and physical fitness to achieve meaningful improvements in performance.

CAN PHYSICAL ACTIVITY, SEDENTARY BEHAVIOUR, AND FITNESS MODIFY THE ASSOCIATION BETWEEN SOCIOECONOMIC STATUS AND CORONARY ARTERY CALCIFICATION? A POPULATION-BASED CROSS-SECTIONAL STUDY

HEILAND, E.G.1, EKBLOM-BAK, E.1, EKBLOM, Ö.1, BÖRJESSON, M.2,3

1. SWEDISH SCHOOL OF SPORT AND HEALTH SCIENCES (GIH); 2. SAHLGRENSKA ACADEMY, GOTHENBURG UNIVERSITY; 3. SAHLGRENSKA UNIVERSITY HOSPITAL

INTRODUCTION: Preclinical markers of coronary artery disease, such as high coronary artery calcification (CAC), have been shown to be associated with socioeconomic status (SES) by residential area in a large Swedish population. However, the prevalence of CAC by other SES measures, such as education, financial strain, and working situation, remains unknown. Furthermore, physical activity's (PA) preventative effects on CAC may differ by SES, sex, domain of physical activity, and fitness level. Thus, in this study we investigated whether the associations between different individual SES factors and CAC, vary by accelerometer-derived physical activity and sedentary behaviour, and fitness.

METHODS: Data were taken from the Swedish CArdioPulmonary bioImage Study (SCAPIS), consisting of 5207 adults (age 50-65 years; 51% women). The SES factors (i.e., education, financial strain, and working situation) were self-reported. CAC was measured using Agaston method of computed tomography, and defined as no CAC (CAC = 0) and any (CAC > 0). Fitness was estimated VO2max derived from a submaximal cycle ergometer test and PA and sedentary behaviours were estimated based on accelerometers worn over 7 days.

RESULTS: Financial strain was associated with CAC in the whole population. However, the association between working situation and financial strain on CAC varied by sedentary behaviour, but only in women. Specifically, sedentary women who were retired or with high financial strain had a greater odds of CAC compared with those who were working/≥50% part-time (Odds Ratio 2.79, 95% confidence interval [1.19-6.52]) or with low financial strain (2.10 [1.14-3.88]). Also, women

who had both poor fitness and SES (either low education, high financial strain, or poor working situation) had a higher odds of CAC than those with both high fitness and good SES, even after adjusting for age, psychosocial factors (i.e., perceived stress, perceived sleep, depressive symptoms), self-reported general health, number of chronic conditions, and lifestyle factors (i.e., current smoking, alcohol abuse, physical activity and sedentary behaviours). This association was also seen in men with poor fitness, but only with the SES factor of low education. In the whole population, having a low moderate-to-vigorous PA level and high financial strain was significantly associated with higher odds of CAC (1.62 [1.05-2.49]).

CONCLUSION: Physical activity and fitness may modify the association between SES and CAC, especially among women. Women who are sedentary and in a poor working or economic situation may be at higher risk of CAC. Fitness levels may help to offset the negative effects of a poor SES on risk of CAC in both men and women.

A NETWORK META-ANALYSIS OF STRATEGIES FOR IMPROVING HORMONAL IMBALANCE IN REPRODUCTIVE-AGED WOMEN WITH OVERWEIGHT OR OBESITY.

RUIZ-GONZÁLEZ, D., CAVERO-REDONDO, I., HERNÁNDEZ-MARTÍNEZ, A., MARTÍNEZ-FORTE, S., SIGNE, A., FERNÁNDEZ-ALONSO, A.M., SORIANO-MALDONADO, A.

UNIVERSITY OF ALMERÍA

INTRODUCTION: The increasing prevalence of obesity worldwide is threatening reproductive function via, among other factors, hormonal disturbances caused by negative feedback between excess adiposity and the hypothalamic-pituitary-ovarian axis. Therefore, this study aimed to evaluate the comparative efficacy of exercise, diet and pharmacological interventions on the hormonal profile of reproductive-aged women with overweight or obesity.

METHODS: A systematic review was performed by searching PubMed, Scopus, Web of Science, PsycINFO, and Cochrane Library from inception to March 23, 2022, for randomized trials assessing the effects of exercise, diet and/or pharmacological interventions on the hormonal profile in reproductive-aged women with overweight or obesity. We performed frequentist random-effect network meta-analyses and rated the certainty of the evidence. The primary outcomes were serum levels of sex hormonal variations (gonadotrophins, androgens, or estrogens). We further conducted sensitivity network meta-analysis of the primary outcomes by differentiating the effects of different pharmacological interventions.

RESULTS: Among 2572 records screened, 78 full texts were assessed for eligibility resulting in 51 trials (4476 women) included, of which 35% presented a high or unclear risk of bias. Compared with control, i) Exercise combined with pharmacological interventions [mean difference (MD) -0.27, 95%CI -0.40 to -0.15 nmol/L] and adding diet interventions [MD -0.23, 95%CI -0.28 to -0.19 nmol/L] significantly reduced total testosterone levels; ii) Exercise combined with diet and pharmacological interventions [MD 3.11, 95%CI 0.79 to 5.44 nmol/L] and exercise plus diet [MD 2.72, 95%CI 1.14 to 4.30 nmol/L] increased sex hormone-binding globulin levels; iii) Exercise combined with pharmacological interventions produced a large decrease in luteinizing hormone (LH) levels [MD -6.03, 95%CI -10.29 to -1.78 IU/L]. Except pharmacological interventions alone, all the interventions improved weight status compared to controls, with diet as the most effective strategy for reducing body mass index (MD -1.82 kg/m2, [95% CI -2.27 to -1.37]) and waist circumference (MD -4.91 cm, [95% CI -7.07, -2.74])

CONCLUSION: Overall, approaches combining exercise and diet modifications with pharmacological interventions were associated with the best improvement in the hormonal profile in women with overweight or obesity. Compared to controls, exercise combined with pharmacological interventions was more effective than other strategies in reducing LH and total testosterone levels, while diet interventions alone or combined with pharmacological interventions produced larger improvements in weight status. In conclusion, strategies to restore an altered hormonal profile for improving fertility might strongly benefit from incorporating lifestyle changes, possibly leading to more promising reproductive outcomes in obese women wishing to conceive.

CHANGES IN MUSCLE STIFFNESS AND THORACIC POSTURE AND ITS ASSOCIATION AFTER COMPUTER TYPING.

OKUDA, Y.1, YAMADA, C.1, UMEHARA, J.2,3, UEBAYASHI, K.4, YANASE, K.1,3

1: DOSHISHA UNIVERSITY 2: KANSAI MEDICAL UNIVERSITY 3: KYOTO UNIVERSITY 4: SUZUKI CLINIC ORTHOPAEDICS RIVERCITY

INTRODUCTION: During shoulder stiffness, the trapezius muscle is frequently perceived as uncomfortable and painful. Although some aspects have been partially clarified, the exact mechanisms of a shoulder stiffness have not been elucidated. Recent research suggested that one risk factor of shoulder stiffness is working for a prolonged time (1). However, the relationship between upper trapezius stiffness and posture during work is unclear. The purpose of this study was to clarify the relationship between upper trapezius stiffness and posture while typing on a computer.

METHODS: Twenty-seven healthy young men performed a 30-min computer typing task while sitting. The shear moduli of the upper trapezius were measured in the sitting position using ultrasonic shear elastography before and immediately after the typing tasks. Additionally, the kyphosis angles of the thoracic spine were measured in the sitting position using the Spinal Mouse before and immediately after the tasks. Wilcoxons signed rank tests were used to compare these

measurements before and after the tasks. Kendalls rank correlation (r) was used to assess the correlation between 1) the change in shear moduli of the upper trapezius before and after typing and 2) the change in thoracic kyphosis angle before and after typing.

RESULTS: Wilcoxons signed rank tests showed that the shear moduli of the upper trapezius were significantly higher after the task than before the task. The thoracic kyphosis angle after the task was significantly higher than before the task. Interestingly, we found a negative correlation between the amount of change in shear moduli of the upper trapezius and the amount of change in thoracic kyphosis angle ($r = -0.265$, $p < 0.01$).

CONCLUSION: The results of this study suggest that 1) computer typing causes stiffness in the upper trapezius, 2) an increase in the thoracic kyphosis angle leads to a rounded shoulder posture after typing, and 3) continuous computer typing in the same posture causes the upper trapezius muscle to become more rigid.

HIP ABDUCTION IS EFFECTIVE FOR STRETCHING THE INDIVIDUAL HAMSTRING MUSCLES

SUZUKI, R.1, HASHIMOTO, K.1, SAKAMOTO, R.1, MURAKAMI, T.1, WAKAHARA, T.1, YANASE, K.1,2

1: DOSHISHA UNIVERSITY 2: KYOTO UNIVERSITY

INTRODUCTION: Stretching in the sagittal plane (hip flexion and knee extension) is generally used for hamstring muscles in rehabilitation. Hamstrings have moment arms at the hip joint in three directions: extension, adduction, and rotation. Since the individual hamstring muscles have different moment arms (1), different stretching positions are predicted to be effective for each muscle. However, it is not clear which direction of stretching is effective for each hamstring. Few studies have examined the effects of stretching positions in the frontal or transverse planes and their combination. The purpose of this study was to clarify the most effective stretching position of the hip joint in the frontal and transverse planes for each hamstring using ultrasonic shear wave elastography.

METHODS: The participants comprised 20 healthy young men (20.9 ± 1.5years, 172.7 ± 5.8 cm, 63.5 ± 7.3 kg). They were randomly placed in nine different positions at 30° of hip flexion and 0° of knee flexion. These positions were combined by three hip adduction/abduction angles (20° adduction, 0° [neutral position], 20° abduction) and three hip rotation angles (30° internal rotation, 0° [neutral position], 30° external rotation): 1) adduction + internal rotation, 2) neutral position + internal rotation, 3) abduction + internal rotation, 4) adduction + neutral position, 5) neutral position and neutral position, 6) abduction + neutral position, 7) adduction + external rotation, 8) neutral position + external rotation, 9) abduction + external rotation. Shear elastic moduli of the right hamstrings (semimembranosus [SM], semitendinosus [ST] and biceps femoris long head [BFlh]) were measured at rest using ultrasonic shear wave elastography in these positions. A two-way repeated measures analysis of variance (ANOVA) and Bonferroni's post hoc test were used to determine the effects of position (adduction/abduction and internal/external rotation) on the shear elastic modulus of each muscle.

RESULTS: The ANOVAs showed the main effects of adduction/abduction in all muscles, and internal/external rotation in the SM and ST with no significant interactions. Post hoc tests showed that the shear elastic moduli of all muscles were significantly higher in the abducted position than in the neutral and adducted positions. In the SM, the shear elastic modulus was significantly higher in the externally rotated position than in the internally rotated position. In the ST, the shear elastic modulus in the externally rotated and neutral positions was significantly higher than in the internally rotated position.

CONCLUSION: The results of this study suggest that 1) the stretching position with a combination of hip abduction and external rotation may be effective for elongating the SM and ST and 2) hip abduction may cause stretching of the BFlh regardless of rotation.

EFFECTS OF 4-WEEK FOAM ROLLING INTERVENTION ON RANGE OF MOTION, MUSCLE STRENGTH AND KNEE PAIN IN PATIENTS WITH KNEE OSTEOARTHRITIS

YANASE, K.1,2, UEBAYASHI, K.3, SUZUKI, H.3

1: DOSHISHA UNIVERSITY 2: KYOTO UNIVERSITY 3: SUZUKI CLINIC ORTHOPAEDICS RIVERCITY

INTRODUCTION: Foam rolling is a self-applied massage using a foam roller and is often used in rehabilitation. Previous studies reported that foam rolling intervention increases range of motion (1) and muscle strength (2). Recently, chronic foam rolling intervention showed to significantly reduce hip pain in patients with hip osteoarthritis (3). Therefore, foam roller intervention may be effective for knee osteoarthritis as well. However, there are no studies investigating improvement in knee function and pain in patients with knee osteoarthritis after foam rolling intervention. The purpose of this study

was to clarify the effectiveness of 4-week foam rolling intervention for improving range of motion, muscle strength and knee pain in patients with knee osteoarthritis.

METHODS: Twenty-three female patients with knee osteoarthritis (age: 74.1±5.1 years, height: 154.2±6.1cm, mass: 60.0±10.0kg) were randomly classified into two groups, a foam rolling group (FR group) and a control group (CON group). The FR group completed foam rolling and strength exercises every day for four weeks, while the CON group performed a sham foam rolling using towel and strength exercises. The participants were evaluated at baseline and after intervention based on the following measurements: knee flexion range of motion (KF ROM), knee extension range of motion (KE ROM), knee flexion maximal voluntary isometric contraction (KF MVIC), knee extension maximal voluntary isometric contraction (KE MVIC), visual analog scale (VAS) of knee pain, and knee pain extent. All measurements were statistically assessed using split-plot 2×2 (group×time) analysis of variance (ANOVA).

RESULTS: ANOVAs showed no significant interaction in all measurements. Time main effects were observed for KF ROM and knee pain extent ($p < 0.05$). The KF ROM was significantly higher at baseline than after intervention, and the knee pain extent was significantly narrower at baseline than after intervention. No changes occurred in KE ROM, KF MVIC, KE MVIC and VAS of knee pain.

CONCLUSION: This study demonstrated that 4-week foam rolling intervention may not be effective for range of motion, muscle strength and knee pain in patients with knee osteoarthritis.

EIGHT WEEKS OF LOW-VOLUME COPENHAGEN ADDUCTOR EXERCISE CAN IMPROVE ADDUCTOR STRENGTH AMONG YOUNG ATHLETES: A CLUSTER RANDOMIZED THREE-ARM CONTROLLED TRIAL

QUINTANA, M.

UNIVERSITY OF OVIEDO

INTRODUCTION: Groin injuries are a major problem in multidirectional sports. In order to reduce the risk of sustaining this injury, modifiable risk factors must be tackled. Some programs have been tested using the Copenhagen Adduction (CA) exercise, an adductor exercise proven to improve hip strength. However, in a real environment these programs are modified and substituted for others with lower volumes. Whether these modified programs are effective in improving adductor strength is yet to be elucidated. The primary aim of this study was to assess the effectiveness of two different-volume CA exercise programs on adductor strength throughout 8 weeks. Additionally, secondary aim was to evaluate whether the expected adaptations were maintained for 3 weeks after the cessation of the adductor exercise programs.

METHODS: This cluster randomized control trial involved 3 U-16 rink hockey teams (n= 40) which acted as low-volume group, high-volume group, or controls. Throughout 8 weeks the intervention groups performed an adductor strengthening programme based on the CA exercise. Meanwhile, control group maintained their usual routine. Adduction strength was tested with the five-second squeeze test at baseline, 2, 8 and 11 weeks. Session adherence and adverse events were recorded daily. Repeated measures ANOVA was used to compare for intra and inter group differences.

RESULTS: Both low-volume and high-volume groups exhibited improvements in adductor strength from baseline to 8 weeks compared to control group ($p< 0.001$). No significant differences were observed between intervention groups, despite the slight advantage of performing a higher volume of adductor exercise (low-volume: 12%; high-volume: 17% improvement; $p= 0.32$). Adherence was 95% and 93% in the low-volume and high-volume groups, respectively.

CONCLUSION: In adolescent rink hockey athletes, it seems reasonable to perform low-volume weekly sessions of CA exercise to enhance adductor strength.

AEROBIC+STRENGTH VS. STRENGTH+AEROBIC: WHICH ONE IS THE MORE EFFECTIVENESS TRAINING PROTOCOL ON COGNITIVE FUNCTION IN HEALTHY-SEDENTARY INDIVIDUALS?

CANLI, U.

TEKIRDAG NAMIK KEMAL UNIVERSITY

INTRODUCTION: An active lifestyle is important in preventing decreases in functional capacity with age There are several studies that point out the positive effect of exercises programmes on life quality in matters of health. Besides the specified factors related to health, it is reported effects of exercises on the brain positively. In the study, it is aimed to determine whether changing the order of the types of exercises applied to the participants have an effect on cognitive functions.

METHODS: Forty-four young sedentary individuals (32 females; 12 males; age: 42.2 ± 9.6 years; the body height: 162.3 ± 7.8 cm, the body mass: 71.3 ± 14.6 kg, BMI: 26.9 ± 5.1 kg/m2) participated in the study. The Go/No-Go test and the d2 test of attention were used to determine cognitive functions. Participants were divided into two homogeneous groups according to their pre-test scores using hypothesis tests. One group of the participants was defined as aerobic+strength group

and the other as strength+aerobic group. Participants joined to exercise programs prepared in accordance with their age levels for 13 weeks. After the exercise program, the tests were applied to the participants once again.

RESULTS: When the parameters representing the attention and inhibition characteristics of the participants were compared in terms of groups, no significant difference was detected in any parameter. Total number of matters processed (Representing participants psychomotor speed) TN: (U= 128.500; p= 0.787). Nonmarked letters (Representing the selective attention of the participants) E1: (U= 125,500; p= 0.705). Number of correct responses in the Go task. GCR: (U= 128,000; p= 0.768). Number of wrong reactions in the Go task. GWR: (U= 128.000; p= 0.769). Correct response latency in the Go task. CRL: (U= 136.000; p= 1.00). Number of correct responses in the No-Go task. NGCR: (U= 103.500; p= 0.221). Number of wrong reactions in the No-Go task. NGWR: (U= 116.500; p= 0.463). Wrong response latency in the No-Go task. WRL: (U= 117.000; p= 0.494).

CONCLUSION: In the literature, no research has been found that examines the change in cognitive functions when aerobic and strength-based exercise protocols are changed during the intervention. Therefore, these research results will form an important reference in the literature on the subject. In the study, changing the order of intervention of aerobic and strength-based approaches in the exercise program does not make a significant difference on the change of cognitive characteristics of individuals.

505 CHANGE OF DIRECTION ASYMMETRY MAGNITUDE DECREASES ACCORDING TO CHRONOLOGICAL AGE IN MALE AND FEMALE ELITE YOUTH TENNIS PLAYERS: RESULTS FROM AN 11-YEAR LONGITUDINAL STUDY.

DHONDT, J., CHAPELLE, L., DHONDT, E., CLARYS, P.

VRIJE UNIVERSITEIT BRUSSEL

INTRODUCTION: Functional interlimb asymmetry is inherent and can be exacerbated by practicing sports. Predominantly unilateral sports, such as tennis, can potentially increase the magnitude of functional asymmetry. For example, tennis strokes are more often executed on one side of the court, as players tend to use their forehand more than their backhand, resulting in side-to-side differences in COD (i.e., change of direction) tasks. Given that asymmetry in COD already occurs at an early age, and that functional asymmetry has been reported to affect athletic performance, this study aimed to examine the development of 505 COD asymmetry longitudinally in youth elite tennis players.

METHODS: The development of COD asymmetry was assessed yearly (up to six years of monitoring) in 323 male and 235 female youth elite tennis players (aged 6-13 years) using an 11-year longitudinal cohort study design (i.e., 2012-2022). For the 505 COD test, the time to cover a 5 m sprint, perform a 180° turn (i.e., either to the left or to the right) and a 5 m sprint back was recorded for both directions of rotation. All players conducted three trials per direction and were given at least one minute of rest between trials to ensure sufficient recovery. At all test occasions, the dominant (i.e., overall best result) and non-dominant performance (i.e., best test result of the opposite rotation direction) values were determined. The magnitude of asymmetry was calculated as follows: ([dominant performance value–non-dominant performance value] / dominant performance value)*100. Linear mixed effects regression models were used to examine the development of performance and asymmetry in the 505 COD according to players' chronological age and sex. To examine the direction of asymmetry as to which 505 COD performance was dominant across the test occasions within players, kappa coefficients were calculated.

RESULTS: Regardless of sex, both dominant and non-dominant performance values significantly improved ($p < 0.001$) with increasing chronological age. In both the male and female players, an increase in chronological age was related to a significant decrease in 505 COD asymmetry magnitude (i.e., -0.17 ± 2.83% per year). Regardless of age, the male players showed a significantly lower 505 COD asymmetry magnitude (i.e., -0.30 ± 1.00 %) compared to the female players. The kappa coefficients were slight for the male (i.e., k-value = 0.02) and poor for the female (i.e., k-value = 0.00) youth elite tennis players.

CONCLUSION: While the yearly 505 COD performances improved over time, the magnitude of 505 COD asymmetry significantly decreased among both male and female youth elite tennis players according to their chronological age. The large standard deviation as well as the poor to slight kappa values emphasize the individual and direction-specific character of the 505 COD asymmetry metric. Therefore, an individual and time-bounded approach seems warranted if practitioners deem to examine the (development of) functional asymmetry.

SPATIAL GENE EXPRESSION IN RAT TENDINOPATHY FOLLOWING ISOMETRIC LOADING

STEFFEN, D., MIENALTOWSKI, M., BAAR, K.

UNIVERSITY OF CALIFORNIA, DAVIS

INTRODUCTION: Tendinopathy is a significant problem in sport because tendon pain associated with movement impairs performance. Approximately 70% of injuries in high level sport are musculoskeletal sprains, strains, and tears. Despite the huge personal and economic cost of tendon injuries, no new treatments have been proposed for more than 25 years. The lack of novel treatments stems from our poor molecular understanding of the tissue. Isometric rehabilitation exercises have can reduce tendon pain (Rio et al., 2015, 2017; van Ark et al., 2016) and improve tendon structure (Baar, 2019). However, the molecular mechanisms behind those improvements and how to optimize rehabilitation remains unknown. It is our hypothesis that shifting the molecular signature of the injured region of the tendon to that of a developing tendon will result in tendon regeneration.

METHODS: To test this hypothesis, we injured the central core of the right patellar tendon. Fourteen days later, the rats performed a single isometric loading session (4 * 30 s) and tendons were collected six, twelve, twenty-four, and forty-eight hours after isometric loading. Tendons were sectioned longitudinally, stained with Hemotoxylin and Eosin, imaged and then solubilized to release mRNA onto 10X Visium Spatial Gene Expression slides. Image and sequencing files were processed in SpaceRanger (version 1.3.1). Spatial variability was assessed using Moran's I and visualized in the Loupe browser.

RESULTS: AABR07000398 was identified as a spatially expressed gene within the rat patellar tendon. Prior to injury, AABR07000398 is expressed exclusively in the paratenon and the connective tissue surrounding the patellar tendon. Following injury, AABR07000398 becomes the most spatially variable gene, with expression highest in the scar tissue.

CONCLUSION: Cells originating from the paratenon contribute to tendon repair (Dyment et al., 2013). AABR07000398 is a LCCL domain contain protein without a known function that in healthy tendon is expressed in the paratenon. Following injury, AABR07000398 expression is upregulated in the scar and may indicate movement of paratenon cells into the scar or that this gene contributes to tendon repair. We are currently determining the effect of isometric loading on AABR07000398 expression levels.

IMMUNE MONITORING ALONGSIDE FACTORS ASSOCIATED WITH UPPER RESPIRATORY ILLNESS IN ELITE SWIMMERS, OVER AN 8-MONTH TRAINING PERIOD LEADING INTO COMPETITION

BAKER, L.H., WELLS, A.V., DESAI, T.

UNIVERSITY OF HERTFORDSHIRE

INTRODUCTION: Upper respiratory illness (URI) is the most frequently reported illness in athletes, resulting in lost training time and reduced success at competition. Due to the high physical demands on elite swimmers, individual athletic monitoring of mucosal immunity and identifying risk factors of URI is paramount. Therefore, the current study investigated the effect of training load (TL), sleep and Epstein Barr Virus (EBV) status on salivary immunoglobulin A (sIgA) and self-reported upper respiratory symptoms (URS).

METHODS: Fourteen elite national and international swimmers (age ± SD= 19.9 ± 0.8 years) were observed for 8-months leading into the Commonwealth Games 2018 and Swim Cup Eindhoven. Self-reported URS, sleep quality and saliva samples were collected weekly. The periodised plan of TL for each week was classified by coaches as low, moderate, and high. When this was compared against swimmer's perceived weekly TL intensity, it was significantly correlated (p=0.003) and thus used for analysis. Blood samples were taken at study commencement to determine EBV status and quantitative sleep parameters were measured use wrist-worn actigraphy for 2-week bouts at different time points during the study.

RESULTS: Over the 8-month observation, 70 URS episodes were recorded, leading to 34 days of missed training. Incidence (p=0.011) and severity (p = 0.001) of URS was significantly higher during high TL. Moreover, duration of URS was significantly longer during moderate (p=0.021) and high (p=0.001) TL, compared to low. Eight swimmers (61%) had evidence of past infection with EBV. However, EBV seropositivity had no relationship with incidence, severity, or duration of URS. When sIgA values were normalised to each individual's mean, relative sIgA concentration was 25% lower during URS than when no symptoms were present (p=0.033). Overall, swimmers spent 58% of the season below their individual 'healthy' sIgA average. Finally, average sleep duration was 6.5 hours and total sleep time was significantly lower during high (p=0.008) and moderate (p=0.002) TL, plus average sleep efficiency was 75% throughout the study.

CONCLUSION: The importance of individual athlete monitoring for coaches and physiologists, to identify those at increased illness risk was highlighted. Identification of risk factors associated with URS, such as increased TL, lowered sIgA and inadequate sleep, may allow for modifications in training or other illness preventative strategies. Overall, elite swimmers showed inadequate sleep, therefore promoting the use of sleep hygiene strategies and napping. There was high prevalence of EBV seropositivity for the elite swimmers; however, it was not a predictor of URS. Low participant numbers could be considered for the lack of significant findings with EBV serostatus; there is ongoing debate that individual data and trends may be more useful in elite athletic research, compared to group statistical analysis.

KINEMATIC ALTERATIONS DURING SINGLE-LEG DROP JUMP DUE TO A SUBJECT-ADAPTED FATIGUING PROTOCOL SUGGESTS INCREASED ACL STRAIN

CAFFI, G., BARTESAGHI, M., ALESSANDRO, C.

UNIVERSITY OF MILANO-BICOCCA

INTRODUCTION: Whether neuromuscular fatigue is a risk factor for anterior cruciate ligament (ACL) injury is still unclear [1]. This may be due to the lack of control over the fitness level of the study participants in previous studies. Here we characterize how a fatiguing exercise session adapted to the fitness level of each participant alters movement kinematics, evaluating whether these alterations may be associated with an increased risk of ACL lesion.

METHODS: Seven healthy male volunteers (height=1.8±0.07 m, weight=73.5±0.07 kg, age=31±5 years) performed four repetitions of a single leg drop jump (SLDJ) task, before and after a fatiguing session on a cycle ergometer (until exhaustion). The power intensity of this exercise was 10% above the anaerobic threshold of each participant, previously identified by means of cardiopulmonary exercise tests. The SLDJ consists of dropping from a step with one leg (first jump) and, upon touching the ground, jumping as high and as fast as possible (second jump), and finally keeping balance on the landing foot. Leg kinematics was monitored using a motion capture system. Repetition-averaged functional outcomes, as well as

joint angles at foot-strikes, toe-offs and at the end of landings (when the knee is maximally flexed), before and after cycling were compared for the dominant (D) and the non-dominant (ND) legs using two-ways repeated measure ANOVA.

RESULTS: The cycling session caused minimal changes in the height of the second jump (D: Δ=0.4±1.6 cm; ND: Δ=-1.2±1.7 cm) and in the time of contact with the ground between jumps (D: Δ=-0.08±0.1 s; ND: Δ=0.04±0.1 s). During the first jump, post-cycling the non-dominant knee tended to be more extended than pre-cycling at foot-strike (Δ=-4.8±6.3°). At the end of the first landing, there was a tendency to reduce ankle dorsiflexion compared to pre-cycling in both legs (Δ=-1.8±2.3°). During the second jump, the knee was more extended than pre-cycling at foot-strike for both legs (Δ=-2.8±3.0°, $p<0.05$). The knee of the dominant leg tended to be more flexed (Δ=4.6±3.8°) and the ankle of the dominant leg tended to be more dorsiflexed (Δ=1.7±1.8°) at the end of the second landing.

CONCLUSION: The increased knee extension at foot-strike indicates a quadriceps-dominant landing strategy, which is known to cause significant ACL strain [2]. The reduced ankle dorsiflexion at the end of the first jump may originate from increased activity of the ankle extensors muscles. Since these muscles are antagonist to the ACL, such a strategy may increase ACL strain too [3]. Therefore, our subject-adapted fatiguing protocol caused kinematic alterations that may be associated with an increased risk of ACL injury. Additional experiments and analyses will be performed to confirm these results.

REST-ACTIVITY CIRCADIAN RHYTHM AND DAYTIME ACTIVITY DURING A WEEK OF SPA STAY

GALASSO, L.1, CASTELLI, L.1, MULÈ, A.1, CIORCIARI, A.1, FORNASINI, F.2, ROVEDA, E.1,3, MONTARULI, A.1,3, ESPOSITO, F.1,3

1UNIVERSITY OF MILAN, 2GB HOTELS ABANO, 3IRCCS ISTITUTO ORTOPEDICO GALEAZZI

INTRODUCTION: The Rest-Activity circadian Rhythm (RAR) is the marker of the 24h activity. Three main parameters describe it: Midline Estimating Statistic of Rhythm (MESOR), Amplitude and Acrophase. It could be altered in several pathological conditions; thus, maintaining a synchronized RAR is usually considered a good mark for the health status. Its natural decline also occurs with aging, accompanied by decreased physical activity levels [1]. Spas are increasingly popular among the elderly and subjects with chronic pathologies for their beneficial effects on health and for promoting active lifestyles [2,3]. The current study aims to assess RAR and daytime activity levels during a week of a Spa stay.

METHODS: 55 participants (mean age 64±11yrs), 19 males (34.5%) and 36 women (65.5%), staying one week at GB-Hotels (Abano Terme, Italy) and undergoing thermal therapies, wore the Actigraph Motion Watch 8 (CamNtech) to gather RAR and daytime activity data and filled a daily diary. Data from Days 2, 3 and 4 and of Days 5, 6, and 7 were mediated to compare changes between the first and the second period of the stay. Comparisons were adjusted for age, BMI, and sex. FORST funded this study.

RESULTS: The female sample reported a significantly higher weekly MESOR (172.9±41.7 vs 146.7±30.7 a.c., p=0.02), MESOR (173.5±41.3 vs 151.2±35.5 a.c., p=0.02) during the first part of the stay, and MESOR (172.3±48.6 vs 120.6±32.6 a.c., p=0.03) and amplitude (148.5±44.3 vs 120.6±32.6 a.c., p=0.03) during the second part of the stay than the male sample. No statistically significant differences were evident in the total sample between the first and second periods of the stay. Daytime moderate activity was significantly higher in the female than the male sample, considering the weekly (3:43±1:07 vs 2:51±0:47 h:mm, p=0.007), the first (3:51±1:06 vs 2:58±0:48 h:mm, p=0.004) and the second part (3:48±1:16 vs 2:48±0:54 h:mm, p=0.006) of the stay. During the stay, the participants spent, on average, 3:25±1:05 h:mm in moderate activity and 1:14±0:10 h:mm in continuous moderate activity per day. No differences were significant between the first and the second part of the stay in the total sample. From the daily diary, the most reported physical activities were walking, swimming, gym use, and thermal-water gymnastics.

CONCLUSION: Considering the 7-day Spa stay, participants reached 300 minutes per week of physical activity. Thus, the thermal centres and Spa stay, in addition to the beneficial effects on health, seem to be favourable in maintaining an active lifestyle.

INTRA-CRANIAL BLOOD VELOCITIES AND NEUROVASCULAR COUPLING ARE MODIFIED BY MATURITY AND EXERCISE TRAINING STATUS DURING YOUTH

TALBOT, J., PERKINS, D., DAWKINS, T., LORD, R., PUGH, C., OLIVER, J., LLOYD, R., AINSLIE, P., MCMANUS, A., STEMBRIDGE, M.

CARDIFF SCHOOL OF SPORT AND HEALTH SCIENCES, CARDIFF METROPOLITAN UNIVERSITY, CARDIFF, UNITED KINGDOM.

INTRODUCTION: Neurovascular coupling (NVC) describes the matching of cerebral blood flow to neural activity. Age-related declines in NVC may contribute to neurocognitive disease during adulthood(1). However, elevated cardiorespiratory fitness at 18 years of age reduces the incidence of neurocognitive disease later in adulthood(2). Yet it is not known if cardiorespiratory fitness influences NVC during adolescence. Therefore, we investigated the effect of exercise training-status on NVC at different stages of youth.

METHODS: Sixty-four endurance-trained (males: n=32, females: n=32) and 57 untrained (males: n=28, females: n=29) youths were characterised as pre- (males: n=33, females: n=29) or post- (males: n=27, females: n=32) peak height velocity (PHV). Middle and posterior cerebral artery blood velocities (MCAv and PCAv) and pulsatility index (MCAPI and PCAPI) were assessed via trans-cranial Doppler ultrasound. Resting cerebrovascular data were collected in 121 youths following 15 minutes of supine rest. Percentage change in intra-cranial velocities (ΔMCAv and ΔPCAv) and pulsatility index (ΔMCAPI and ΔPCAPI) were collected during five repetitions of a 30 second visual stimulus in 98 youths. Main effects of maturity status, biological sex and training status were determined via ANOVA. Between-group differences were determined by independent t-tests. Data are reported as group means (±SD).

RESULTS: Post-PHV youth exhibited lower resting MCAv (P≤0.001) and PCAV (P=0.009) than pre-PHV counterparts. Resting MCAv (P≤0.001) and PCAv (P=0.039) were lower in males when compared to females. Resting MCAv was higher in trained youths when compared to untrained counterparts (P=0.010), but there were no training effects during post-hoc comparisons (all; P≥0.05). The ΔPCAv and ΔMCAv during the NVC stimulus were similar in pre- and post-PHV youth (P=0.135 and P=0.671), males and females (P=0.120 and P=0.490) and trained and untrained youth (P=0.204 and P=0.549). Pre-PHV untrained males (16 [12] vs 7 [5] %; P=0.007) and females (18 [11] vs 6 [6] %; P=0.002) had a higher ΔPCAPI than their post-PHV untrained counterparts. However, the ΔPCAPI was similar in pre- and post-PHV trained males (P=0.840) and females (P=0.497). Furthermore, pre-PHV untrained males had a larger ΔPCAPI than trained counterparts (16 [12] vs 8 [6] %; P=0.023).

CONCLUSION: Endurance exercise training elevates MCAv during youth and dampens changes in cerebrovascular pulsatility during visual cognitive tasks in children. Therefore, exercise training during youth modifies cerebrovascular haemodynamics which may protect long-term neurovascular function.

CYCLING CRITICAL POWER IS RELATED TO HEMOGLOBIN MASS BUT IS INDEPENDENT OF SEX AFTER ACCOUNTING FOR BODY SIZE AND COMPOSITION

CASWELL, A., TRIPP, T.R., KONTRO, H., MACINNIS, M.J.

UNIVERSITY OF CALGARY

INTRODUCTION: Critical power (CP) is a submaximal aerobic exercise threshold that represents the highest workload sustained entirely through oxidative metabolism. While convective oxygen delivery, which is largely based on hemoglobin mass (Hbmass), may be an important determinant of submaximal aerobic exercise thresholds, to our knowledge, the relationship between Hbmass and CP has not been explored. The primary objectives of this study were to investigate (i) relationships between Hbmass and CP using absolute values and after normalizing data to body mass (BM) and fat-free mass (FFM); and (ii) sex differences in relative Hbmass and relative CP normalized to FFM. We hypothesized that (i) due to the confounding effect of body size, the strength of the relationship between absolute Hbmass and CP would be weakened by normalizing data to BM and FFM; and (ii) normalizing data to FFM would eliminate any sex difference in relative Hbmass and CP.

METHODS: 19 participants (n= 10 females, n= 9 males) performed a 25W/min incremental exercise test to determine maximal oxygen uptake (VO2max). On a separate day, participants performed a modified carbon monoxide rebreathe technique to measure Hbmass and underwent a DXA scan to obtain FFM. Finally, participants completed 3-4 constant load cycling trials to determine CP. Data were analyzed using simple linear regression to investigate the relationships between total Hbmass (g) and absolute CP (W) and between relative Hbmass (g/kg BM and g/kg FFM) and relative CP (W/kg BM and W/kg FFM). Independent t-tests were used to investigate sex differences in relative CP and Hbmass (normalized to FFM).

RESULTS: There was a strong, positive (r=0.724) and statistically significant relationship between total Hbmass and absolute CP (p<0.001, R2= 0.524). Positive, moderate (r= 0.648 and r=0.575, respectively) and statistically significant relationships were also found between relative Hbmass (BM and FFM, respectively) and CP normalized to BM (p=0.003, R2=0.420) and FFM (p=0.01, R2=0.331). When comparing males and females matched for VO2max (mean±SD: 58.5±6.8 vs. 59.0±8.4 mL/kg FFM/min; p=0.88), differences in relative Hbmass (15.2±1.7 vs. 14.1±1.4 g/kg FFM; p=0.13) and relative CP (3.5±0.6 vs. 3.7±0.9 W/kg FFM; p=0.52) were not statistically significant.

CONCLUSION: Hbmass explained approximately one-third to one-half of the variation in CP, depending on how data were expressed: Normalizing data to BM or FFM reduced the strengths of the correlations between Hbmass and CP compared to the relationship between absolute values. Additionally, this study supports a lack of sex differences in relative Hbmass and CP when data are normalized to FFM and the sexes are matched for fitness. To complement this cross-sectional study, future studies should examine if increasing Hbmass through an intervention (i.e., blood transfusion) also increases CP.

DOES CHRONOTYPE AFFECT VO2MAX IN HEALTHY ADULTS?

EZZY, Q., HABAY, J., ROELANDS, B.

VRIJE UNIVERSITEIT BRUSSEL

INTRODUCTION: Recently a relationship was found between athletic performance and chronotype: an individual's alertness levels during the day. It has been discovered that morning types report to be less fatigued and perform better in the morning compared to evening types and that evening types are more susceptible to decreased performance when performing on a time of day that is not optimal according to their chronotype activity level. However, it has not yet been investigated whether VO2max, an objective marker of aerobic performance, is affected by chronotype.

METHODS: Sixty-five healthy adults, (32 males and 33 females) aged 31 +- 9 years old were included in the analysis. The subject sample had a VO2max of 47,05 +- 8,50 ml/kg^-1/min^-1, BMI of 22,5 +- 2,45 kg/m^2, and fat percentage of 20,13 +- 7,07 %. Subjects performed a maximal incremental exercise test on a cycling ergometer, starting at a power output of 80W and increasing by 30W every three minutes. Post-exercise, self-reported data of the Single Item Chronotyping scale (SIC) was collected to determine the chronotype of participants. The SIC consists of six options for identifying chronotype: 1. Morning type, 2. Evening type, 3. Daytime sleepy type, 4. Daytime type, 5. Highly active type, 6. Moderately active type. Time of day and season were added in the analyses as covariates.

RESULTS: No significant differences in VO2max were observed when comparing groups of different chronotypes (p = 0,089) when correcting for the time of day (p = 0,141). However, correcting for the season showed a trend to significance (p = 0,097). Mean VO2max values were observed to be highest for subjects of chronotype 3 (50,10 +- 9,03 ml/kg^-1/min^-1) and lowest for subjects of chronotype 4 (42,67 +- 8,29 ml/kg^-1/min^-1).

CONCLUSION: These findings contribute to the understanding of the effect of chronotype on physical performance and suggest that VO2max in healthy adults is less affected by chronotype compared to other factors determining athletic performance. However, a trend to significance was found in the data, suggesting that chronotype remains a factor to be studied in relation to physical performance. Coaches should take into account athlete's individual chronotypes and the time of day that training sessions are scheduled. Further research should explore whether other variables affect the relationship between chronotype and VO2max and how chronotype affects the factors that determine VO2max.

ACUTE EFFECTS OF LONG-DISTANCE RUNNING ON HEMATOLOGIC MARKERS (ANEMIA PHENOMENON) IN HEALTHY YOUNG MALE

SURONO, S., MUSLIM, B.A., ALI, M.A., ANGGITA, G.M., KURNIAWATI, D.M.

MINISTRY OF YOUTH AND SPORT, REPUBLIC OF INDONESIA; FACULTY OF SPORTS SCIENCE, UNIVERSITAS NEGERI SEMARANG, REPUBLIC OF INDONESIA; FACULTY OF MEDICINE, UNIVERSITAS DIPONEGORO, REPUBLIC OF INDONESIA

INTRODUCTION: Anemia caused by physical exercise is known as pseudo-anemia and it is a positive adaptation to aerobic exercise. Hemoglobin level is decreased because aerobic exercise expands the baseline plasma volume; this reduces the concentration of red cells, which contain the hemoglobin. This increase in plasma volume dilutes the number of red blood cells per volume of blood leading to a pseudo-anemia. On the other hand, urban sports such as 10 Km running have become part of the lifestyle and a platform for social activity. However, there are only a few studies that investigate the acute effect of long-distance running on anemia-related variables, particularly before, 24 h post-workout, and 48 h post-workout.

METHODS: This is quasi-repeated measures study. Ten healthy males were voluntarily in this study (19±1.00yrs, BMI 23.0±2.50). Subjects did not do any workouts for 7 days prior to the experiment. The running intensity was 70%–80% of MHR, and subjects must finish 10 Km. Venous blood collection performed at pre-running, 24 h post-running, and 48 h post-running to measure Hemoglobin (Hb) by cyanide-free hemoglobin spectrophotometry, Erythrocyte, Mean Corpuscular Hemoglobin (MCH), Mean Corpuscular Hemoglobin Concentration (MCHC), Mean Corpuscular Volume (MCV), and Red Blood Cell Distribution Width (RDW) by electrical impedance (hematologic analyzer). All the hematologic measurements were performed at the CITO laboratory in Setiabudi, Semarang. All of the study's procedures have been approved by the institutional health research ethics committee, UNNES (120/KEPK/EC/2020). One-way repeated measures ANOVA was performed to elucidate the differences in means on endpoints. A statistical level of p< 0.05 was accepted. All data are expressed as mean ± SEM.

RESULTS: Hb (gr/dl) were declined at 24h post-running (15.93±0.35), and significant at 48h post-running (15.64±0.51, p< 0.05) from pre-running (16.30±0.38). Erythrocytes (10^6/uL) were declined at 24h (5.54±0.34), and remarkable at 48h (5.42±0.39) from pre-running (5.67±0.37) as p< 0.05. In addition, neither at 24h (28.86±1.87) nor at 48h (28.96±1.87) of MCH (pg) were not different from pre-running (28.85±1.86) as p> 0.05. Furthermore, MCHC (gr/dl) decreases were not significant, at 24h (35.11±0.38), and at 48h (34.98±0.29) compared to pre-running (35.13±0.44) as p> 0.05. Moreover, there were no significant differences in changes of MCV (fl), pre-running (82.21±5.42), 24h (82.14±5.40), and 48h (82.77±5.39) as p> 0.05. At last, RDW (%) were significantly increased both at 24h (13.17±0.80), and at 48h (13.13±0.67) compared to pre-running (13.07±0.77) as p< 0.05.

CONCLUSION: Long-distance running as aerobic physical exercise is able to induce pseudo-anemia, and it is confirmed in the previous studies as the normal physiological adaptation of exercise.

REDUCING METABOLIC INSTABILITY ON TRANSITION TO CONSTANT WORK RATE EXERCISE DECREASES STEADY-STATE OXYGEN UPTAKE.

MARINARI, G., IANNETTA, D., HOLASH, R.J., ZAGATTO, A.M., TRAMA, R., KEIR, D.A., MURIAS, J.M.

UNIVERSITY OF CALGARY

INTRODUCTION: Metabolic instability represents the integrative physiological mechanisms underpinning the higher oxygen cost that develops above the moderate intensity domains (1). Although the early metabolic disruption at the onset of exercise might be largely responsible for this metabolic instability, no study has manipulated the exercise protocol to mitigate the early reliance on anaerobic substrate sources prior to attaining VO2 steady state. The aim of this study was to investigate whether approaching a target intensity within the heavy intensity domain through a ramp-to-steady state transition as compared to a square-wave transition would decrease the metabolic cost of steady state exercise.

METHODS: Ten active males and four females participated in this study. VO2max and the power output (PO) demarcating the moderate, heavy, and severe intensity domains were determined through the step-ramp-step protocol (2). On subsequent visits, participants randomly performed: i) a 21-min square-wave transition from 20 W to a constant work rate (CWR) PO corresponding to 75% of the difference between the PO at the gas exchange threshold and the maximal metabolic steady state; ii) a ramp (20 W·min-1) to the same CWR (rCWR) intensity. VO2, lactate concentration ([Lac]; collected every 3-min) and muscle oxygen saturation (SmO2) from the vastus lateralis were measured. The VO2 and VO2 gain (VO2-G) responses during the first 10-min of steady state were smoothed with a 1-min moving average and analysed using the Statistical non-Parametric Mapping method (3). SmO2 during the same 10-min were analysed using a 2-way ANOVA. The average steady state [Lac] collected within the steady state VO2 window, was analysed using paired student t-test. Significance was set at $P < 0.05$.

RESULTS: VO2max was 48.6 ± 8.1 mL/min/kg. VO2 and VO2-G profiles during the rCWR condition (2486 ± 22 mL/min and 10.7 ± 0.2 mL/min/W, respectively) were lower ($P < 0.05$) compared to the CWR condition (2570 ± 24 mL/min and 11.3 ± 0.2 mL/min/W, respectively) during the entire 10-min of steady state. The averaged [Lac] during the rCWR condition (3.39 ± 1.09 mM) was lower ($P < 0.05$) than the CWR condition (4.09 ± 1.25 mM). Whereas SmO2 was stable within the entire 10-min of VO2 steady state during the rCWR condition ($P > 0.05$), the CWR condition elicited unstable responses for the first 8-min at VO2 steady state ($P < 0.05$).

CONCLUSION: This study showed that mitigating the early metabolic perturbation from the square-wave CWR transition (represented by the oxygen deficit), through a rCWR transition to the same PO within the heavy intensity domain, leads to a lower metabolic instability as indicated by a decreased steady state [Lac], which resulted in a reduced VO2 and VO2-G. An improved muscle oxygenation dynamic during the rCWR compared to the CWR might play a primary role for metabolic stability and thus for the decreased metabolic cost of steady state exercise.

DIFFERENT METHODS FOR DETERMINING THE BOUNDARY DEMARCATING THE MODERATE- FROM THE HEAVY-INTENSITY DOMAIN: REASSEMBLING THE IMPORTANCE OF THE LACTATE THRESHOLD

RUIZ-RIOS, M., GOROSTIAGA, E.M., MARTÍNEZ-LABARI, C., MALDONADO-MARTIN, S., GARCIA-TABAR, I.

UNIVERSITY OF THE BASQUE COUNTRY

INTRODUCTION: Aerobic capacity is one of the most powerful independent predictors of death risk among middle-aged and older men adults [1]. For many years, the Lactate Threshold (LT) was considered the boundary demarcating the moderate- from the heavy-intensity domain according to the well-established, but underutilized, domain schema of exercise intensity [2]. However, percentages of maximal anchors, such as percentages of maximal heart rate (%HRmax) or maximal oxygen uptake (VO2MAX), is the most common method utilized to prescribe training intensities. In healthy middle-aged and older men, the Six-minute Walk Test (6MWT) is also a widely used test for those same purposes. To our knowledge, the comparison of these methods for determining the boundary demarcating the moderate- from the heavy-intensity domain in middle to aged adults has been little investigated. Therefore, the aim of the study was to investigate the applicability of the LT to predict and demarcate the boundary from the moderate- to the heavy-intensity domain (HRm-h) in comparison with the 6MWT.

METHODS: Twelve participants performed 0) a familiarization procedure, 1) a cardiopulmonary treadmill test (CPX) [3], 2) the 6MWT [4], and 3) a discontinuous incremental field test for LT determination [5]. HRm-h was determined using 1)

HRmax obtained in the CPX, 2) peak HR obtained in the 6MWT, and 3) HR at the LT, and stratified by exercise intensity domains [1].

RESULTS: The HRm-h determined by the CPX and the 6MWT was overestimated by 10-20% (P<0.05; ES: 0.5-1.0) compared against the gold-standard LT. HRm-h stratification indicated participants fall into the very light to the vigorous intensity domains. Concerning the HR-6MWT m-h, 8, 8, 75, and 8% of the participants fall into the very light, light, moderate, and vigorous zones, respectively. These percentages for the HR-LT m-h were 25, 33, 33, and 8%, respectively.

CONCLUSION: The wide range of %HRmax at which LT occurs suggests that physical activity programs using exercise intensity prescriptions based on percentages of VO2MAX or HRmax would lack uniformity in the metabolic stress responses among individuals. Implementation of LT testing in physical activity programs might help to improve the quality of the aerobic capacity exercise training in middle-aged and older men.

NO POST-EXERCISE HYPOTENSION RESPONSE AFTER RESISTANCE EXERCISE SESSION REGARDLESS OF THE SET CONFIGURATION IN PHYSICALLY ACTIVE YOUNG PARTICIPANTS

RÚA-ALONSO, M.1,2,3, MAYO, X.1,4, RIAL-VÁZQUEZ, J.1,4, FARIÑAS, J.1, NINE, I.1, IGLESIAS-SOLER, E.1

1: PERFORMANCE AND HEALTH GROUP, UNIVERSITY OF A CORUNA; 2: POLYTECHNIC OF GUARDA; 3: RESEARCH CENTER IN SPORTS SCIENCES, HEALTH SCIENCES AND HUMAN DEVELOPMENT; 4: KING JUAN CARLOS UNIVERSITY

INTRODUCTION: Post-exercise hypotension (PEH) response after resistance exercise (RE) can be influenced by multiple factors such as the calculation approach (1), the participants characteristics or the exercise protocols (1,2). Set configuration has been shown to be a modulating factor for PEH following a single resistance exercise (3), however this has not been demonstrated for routines composed of several RE involving major muscle groups. The aim of this study was to compare the effect of two different whole-body RT set configuration protocols on PEH response and vascular tone.

METHODS: 32 apparently healthy young participants performed in a random order one control session (CON) and two RT sessions (leg extension, leg curl, lat pull, bench press and parallel squat) differing in the set configuration but with the same intensity (15RM load), volume (200 repetitions) and total resting time (360 s between sets for each exercise and 3 min between exercises): a long set configuration (LSC: 4 sets of 10 repetitions with 2 min rest between sets) and a short set configuration session (SSC, 8 sets of 5 repetitions with 51 s rest between sets). Beat-to-beat blood pressure (BP) was assessed by photoplethysmography (Task Force Monitor, CNSystems, Graz, Austria). Data recordings were performed for 10 min before and for the intervals 20–30 and 30–40 min after each session. PEH was determined by different approaches: I = absolute values, II = [(post-exercise – pre-exercise)/pre-exercise], III = (post-exercise – pre-exercise), IV = (post-exercise – post-control), and V = [(post-exercise – pre-exercise) – (post-control – pre-control)] (2). Additionally, low frequency of systolic BP oscillations (LFsBP) was evaluated.

RESULTS: BP response (i.e., systolic, diastolic, and mean arterial pressure) showed no main effects or interactions among protocols ($p > 0.05$), regardless of the PEH approaches used. Similarly, no main effects or interactions were found for LFsBP ($p > 0.05$).

CONCLUSION: Our findings showed that neither session resulted in a PEH response or change in vascular tone. Both sessions reached far from muscle failure (3) and were performed by young, healthy, physically active individuals with low-normal pre-exercise values (4,5). Therefore, besides training protocol characteristics, the profile of our sample might not be suitable for induce an overall (i.e., at the sample level) hypotensive effect after an acute RE session. Nevertheless, individual responses showed that some participants did experience reductions in BP, according to previous studies that reported that only approximately 65% of people have HPE and sometimes even post-exercise values increase (4,5).

GUT MICROBIOTA AND PERIPHERAL BLOOD MICRORNAS ARE DIFFERENTIALLY EXPRESSED IN ENDURANCE RUNNERS COMPARED WITH ENDURANCE CYCLISTS

SHALMON, G., IBRAHIM, R., ISRAEL, I., GRAD, M., SHAPIRA, G., SHOMRON, N., YOUNGSTER, I., SCHEINOWITZ, M.

TEL AVIV UNIVERSITY

INTRODUCTION: To date, gut microbiota composition has not been fully investigated in endurance athletes, from different fields, nor the peripheral blood mononuclear cells (PBMC) microRNAs' expression levels. AIM: Determining gut microbiota composition and microRNAs' expression in runners and cyclists, female and male athletes.

METHODS: 31 subjects (13 males) with a mean age of 43.3±7.5 y participated in our study. They included 16 runners, 9 cyclists, and 6 control subjects (active but not competitive). Fecal specimens were collected and analyzed for taxonomic profiling using MetaPhlAn2 to compare the relative abundances of species between experimental conditions based on the results of 16S rRNA analysis. Each participant underwent a maximal oxygen consumption test and a time-to-

exhaustion test at 85% of the measured VO2max. Blood lactate was collected every 5 minutes during the tests as well as venous blood, before and after the tests, to assess microRNA blood levels.

RESULTS: Bacterial alpha-diversity showed a significant difference [P=0.02] between male runners [n=13] and male cyclists [n=6]. Bacterial beta-diversity showed a significant difference [P=0.04] between female [n=8] and male [n=21] athletes. Five bacteria showed higher expression in runners compared to cyclists. There was a significant correlation between some bacteria, including lactate-utilizing bacteria, and improved exercise performance and delayed fatigue in runners, but not in cyclists. Compared with the time-to-exhaustion test, the maximal oxygen consumption test led to higher expression of PBMC microRNAs in runners and cyclists. The runners expressed a higher number of PBMC microRNAs and more diverse ones than the cyclists.

CONCLUSION: Male runners show greater bacterial species richness compared with male cyclists, but not with female runners and cyclists. PBMC microRNAs expression appears to be sport-specific (over-expressed in runners vs. cyclists), and related to exercise intensity. These findings emphasize the differences between runners and cyclists, probably due to the difference in physiological and biomechanical strains related to the mode of activity during training.

THE POST-PRANDIAL PLASMA AMINO ACID RESPONSE DOES NOT DIFFER FOLLOWING THE INGESTION OF A SOLID VERSUS A LIQUID MILK PROTEIN PRODUCT IN HEALTHY ADULT FEMALES

VAN LIESHOUT, G., TROMMELEN, J., NYAKAYIRU, J., VAN KRANENBURG, J., SENDEN, J., VERDIJK, L., VAN LOON, L.

MAASTRICHT UNIVERSITY

INTRODUCTION: Dietary protein digestion and amino acid absorption kinetics are modulated by numerous factors that, together, define the food matrix. It has been speculated that protein ingested in liquid form is more rapidly digested and absorbed when compared to ingestion in a solid form. Here we assessed the post-prandial plasma amino acid availability following the ingestion of a single bolus of protein provided in either liquid or solid form.

METHODS: 12 healthy, young females were included in this randomized cross-over study. On two separate test days, participants ingested 20 g milk protein concentrate in solid form (protein bar) or in liquid form (protein drink). Products were composed of the same ingredients and, as such, also had the same macro- and micronutrient composition. On both test days, arterialized blood samples were collected frequently for up to 4 h following protein ingestion to assess the post-prandial rise in plasma amino acid concentrations. Plasma amino acid concentrations were compared between treatments by two-factor repeated-measures ANOVA with time and treatment as within-subject factors. Incremental area under the curve, peak concentration and time to peak for plasma amino acid concentrations were compared between treatments using a paired t-test.

RESULTS: Protein ingestion strongly elevated circulating plasma amino acid concentrations (time effect: P<0.001), with no significant differences between treatments (time*treatment effect: P=0.088). The incremental area under the curve of the post-prandial rise in total plasma amino acid concentrations did not differ following bar versus drink consumption (160±73 vs 160±71 mmol·L-1·4 h-1, respectively; P=0.992). Furthermore, no differences in peak amino acid concentrations (3872±481 vs 3833±867 µmol·L-1, respectively; P=0.891) or time to peak (56±20 vs 53±20 min, respectively; P=0.674) were observed between protein bar and drink consumption.

CONCLUSION: Ingestion of protein in liquid or solid form does not modulate post-prandial amino acid availability in healthy, female adults. Differences in protein digestion and amino acid absorption kinetics due to differences in food matrix are not merely attributed to the protein being consumed in solid or liquid form.

POSTPRANDIAL PLASMA AMINO ACID, APPETITE, AND ENERGY INTAKE RESPONSES TO PLANT-BLEND PROTEIN INGESTION IN HEALTHY YOUNG ADULTS

ROGERS, L.M.1, BELFIELD, A.E.1, KORZEPA, M.A.1, MARSHALL, R.N.1, GRITSAS, A.2, CHURCHWARD-VENNE, T.A.2, BREEN, L.1

<1> UNIVERSITY OF BIRMINGHAM, <2> MCGILL UNIVERSITY

INTRODUCTION: The muscle anabolic response to some plant-derived proteins is inferior to that of animal-derived proteins, due to a lower content and specific deficiencies of essential amino acids (EAA) (1). Blending different plant-derived proteins could compensate for these deficiencies and may augment postprandial aminoacidemia over single-source plant proteins (2), with possible implications for appetite regulation (3). Indeed, perceived appetite and orexigenic hormonal responses to different sources of dietary protein are yet to be fully elucidated. Therefore, this study assessed post-prandial plasma amino acid and ghrelin concentrations, appetite sensations, and ad libitum energy intake following ingestion of a pea-rice protein blend, compared with pea-only and whey protein.

METHODS: In a randomised, double-blind, crossover design, 11 healthy adults (M n=5, F n=6; Mean±SD age: 22±3 years; BMI: 23±3 kg/m2) ingested 0.3 g·kg-1·mass-1 of pea-rice blend, pea protein or whey protein. Arterialised blood samples were collected in the fasted state and over 240-min postprandially. Plasma concentrations of amino acids and ghrelin

were assessed via ultra-performance liquid chromatography mass spectrometry (UPLC-MS) and ELISA, respectively. Appetite sensations over 240-min were measured via Visual Analogue Scales. An ad libitum buffet-style test meal was administered after each trial to assess energy intake. Time-dependent and -independent variables were analysed via repeated measures ANOVA or mixed-effects models, depending on missing data points.

RESULTS: Mean plasma EAA incremental area the under curve (iAUC) was higher in Whey, compared to Pea ($p < 0.01$; mean diff (95% CI): 44218 (15806 to 72631) µmol·240 min·L-1) and Blend ($p < 0.01$; 14358 (16031 to 101121) µmol·240 min·L-1), with no differences between Pea and Blend ($p = 0.67$). Plasma total amino acid iAUC was not different between treatments (all $p > 0.05$). Plasma ghrelin (total) concentrations and subjective ratings of hunger, fullness, and food preferences were transiently altered after protein ingestion (time effect: $p < 0.04$ for all), with no differences between treatments ($p > 0.05$ for all). Ad libitum intake of total energy, carbohydrate, fat, and protein during the test meal were not different between treatments (all $p > 0.05$).

CONCLUSION: In healthy adults, ingestion of the pea-rice protein blend did not augment postprandial aminoacidemia above pea protein, perhaps attributable to only marginal differences in the essential amino acid composition of these proteins. Despite greater plasma essential aminoacidemia following Whey compared to Blend and Pea, no between-trial differences in appetite or energy intake responses were apparent, potentially as the plasma bioavailability of total amino acids did not differ between treatments.

HIGHER MUSCLE PROTEIN SYNTHESIS RATES FOLLOWING INGESTION OF A BEEF-CONTAINING OMNIVOROUS MEAL COMPARED WITH AN ISONITROGENOUS VEGAN MEAL

PINCKAERS, P.J.M.1, DOMIC, J.2, PETRICK, H.L.1, HOLWERDA, A.M.1, HENDRIKS, F.K.1, HOUBEN, L.H.P.1, SENDEN, J.M.1, DE GROOT, L.C.P.G.M.2, VERDIJK, L.B.1, SNIJDERS, T.1, VAN LOON, L.J.C.1

<1> MAASTRICHT UNIVERSITY, <2> WAGENINGEN UNIVERSITY

INTRODUCTION: Plant-derived proteins are considered to have lower anabolic potential compared to animal-derived proteins. The anabolic properties of isolated proteins do not necessarily reflect the anabolic response to the ingestion of whole-foods. The presence or absence of the various components that constitute the whole-foods matrix can strongly impact protein digestion and amino acid absorption and, as such, modulate post-prandial muscle protein synthesis rates. So far, no study has compared the anabolic response following ingestion of an omnivorous versus a vegan meal. In this study, we compared post-prandial muscle protein synthesis rates following ingestion of a whole-foods meal (providing 36 g protein) containing 100 g lean ground beef, versus the ingestion of an isonitrogenous, isocaloric whole-foods meal containing only plant-based protein sources (providing 36 g protein) in vivo in healthy, older men and women.

METHODS: In a randomized, counter-balanced, cross-over design, 16 healthy older (65-85 y) men and women underwent 2 experimental test days. On one test day, participants consumed a whole-foods omnivorous meal containing beef as the primary source of protein (36 g protein; MEAT). On the other test day, participants consumed an isonitrogenous and isocaloric whole-foods vegan meal containing only plant-based whole foods as the main sources of protein (36 g protein; PLANT). Primed continuous L-[ring-13C6]-phenylalanine infusions were applied. Blood samples and muscle biopsies were collected frequently for 6 h to assess post-prandial plasma amino acid profiles and muscle protein synthesis rates. Data are presented as mean±SD and were analyzed using two way-repeated measures ANOVA and paired samples t-tests. Effect sizes were estimated by Cohen's d.

RESULTS: MEAT ingestion increased plasma essential amino acid availability more than PLANT ingestion over the 6 h post-prandial period (time x treatment interaction: $P<0.001$) resulting in a greater incremental area under curve (87±37 vs 38±54 mmol/6h/L respectively; paired t-test: $P<0.001$; $d=1.16$). The greater post-prandial plasma essential amino acid availability was accompanied by ~18% higher peak essential amino acid concentrations (1314±144 vs 1111±193 µmol/L respectively; paired t-test: $P<0.001$; $d=1.07$). Ingestion of MEAT resulted in ~49% higher muscle protein synthesis rates when compared to the ingestion of PLANT over the 6 h postprandial period (0.052±0.023 vs 0.035±0.021 %/h, respectively; paired samples t-test: $P=0.037$; $d=0.57$).

CONCLUSION: Ingestion of a whole-food meal containing beef results in greater post-prandial muscle protein synthesis rates when compared to the ingestion of an isonitrogenous and isocaloric whole-foods plant-based meal in healthy, older adults.

EFFECTS OF SHORT-TERM LOW ENERGY AVAILABILITY ON AEROBIC AND ANAEROBIC ENDURANCE CAPACITY IN PHYSICALLY ACTIVE ADULTS

EHLING, H., KIRMSE, M., SIPPL, J., PLATEN, P.

FACULTY OF SPORT SCIENCE, RUHR UNIVERSITY BOCHUM

INTRODUCTION: Low energy availability (LEA) is the underlying cause of the "relative energy deficiency syndrome in sports" (RED-S). RED-S can have serious effects on many body systems, resulting in short- and long-term impairment of optimal health and performance (1). It might lead to decreased muscular glucose utilization, mobilization of fat stores, slowing of metabolism, and decreased endurance performance (2). The study aims to investigate the short-term adaptations of aerobic and anaerobic endurance capacity to determine the effects of different LEA gradients to gain a deeper understanding of its symptoms.

METHODS: 22 participants (f=11, m=11, age 24±1 y, weight 72±12 kg, height 178±8 cm) were included in the randomized controlled study. Over 5 days, 3 different gradients of EA, 45 (control), 30 (EA30) and 10 (EA10) kcal/kg FFM/day, respectively, were used. An incremental treadmill test to exhaustion was performed during pre- and postintervention testing. Submaximal respiratory exchange ratio (RER), absolute V'O2max (L/min) and relative V'O2max (ml/min/kg), maximal heart rate (bpm), submaximal rate of perceived exertion (RPE) and the courses of lactate and glucose concentration in capillary blood samples were measured at the end of each increment and after exhaustion. BIA was performed to determine body weight and composition (fat free mass, fat mass, total body water). All variables were analyzed with one-way ANOVA. All data is presented as means ± SD.

RESULTS: Body weight (Δ: -2.1±1.0 kg; p<0.001) and fat mass (Δ: -1.0±0.7 kg; p=0.04) were reduced in EA10 compared to control. After treatments, the performance parameters showed no significant differences between groups (control, EA30, EA10) in absolute V'O2max (Δ: 0.03±0.24; 0.10±0.16; -0.13±0.05 L/min; p=0.059) and relative V'O2max (Δ: 0.50±3.11; 1.43±2.07; -0.50±1.98 ml/min/kg; p=0.35), maximal heart rate (Δ: -4.50±4.12; -0.86±7.95; -9.40±9.45 bpm; p=0.211), submaximal RPE and the courses in lactate and glucose concentration, respectively (p>0.05). Without influencing maximal (4.3±0.5 m/s) performance, submaximal RER was reduced after increment 1 in EA10 compared to control (Δ: -0.05±0.02; p=0.037), and after increment 2 in EA10 compared to control (Δ: -0.08±0.01; p<0.001) and to EA30 (Δ: -0.05±0.01; p=0.001).

CONCLUSION: The short-term intervention of nutritional energy restriction did not compromise running performance, however caused a metabolic shift from utilization of glucose to increased utilization of fat. A short-term energy restriction might have no negative effect on endurance running performance because of the reduced body weight due to the negative energy balance. Detrimental long-term effects should be considered to protect the athlete's health and performance by avoiding a negative energy balance over a longer period.

EVEN AT VERY LOW DOSE, CAFFEINE IMPROVES VERTICAL JUMP PERFORMANCE IN A DOSE-INDEPENDENT MANNER

MATSUMURA, T.1, TAKAMURA, Y.1, FUKUZAWA, K.1, NAKAGAWA, K.1, TOMOO, K.1,2, NONOYAMA, S.1, TSUKAMOTO, H.1, SHINOHARA, Y.1, IEMITSU, M.1, NAGANO, A.1, ISAKA, T.1, HASHIMOTO, T.1

1 RITSUMEIKAN UNIVERSITY; 2 PURDUE UNIVERSITY

INTRODUCTION: As we have recently reported (1), moderate doses (i.e., 3–6 mg/kg) of caffeine enhance various athletic performances (1,2), including jumping (3) which is one of the critical components for many sports. Yet, low dosage (i.e., ≤3 mg/kg) caffeine's ergogenicities have also been discussed (4). Lower dose caffeine may become a safe and effective ergogenic strategy, but it is unclear whether the ergogenic effect of caffeine on jump performance is dose-response. Therefore, we examined the effect of very low (i.e., 1 mg/kg) to moderate doses of caffeine, including the upper and lower limits of commonly utilized ergogenic doses (i.e., 3 and 6 mg/kg [5]), on vertical jump performance.

METHODS: Thirty-two well-trained collegiate sprinters and jumpers performed three countermovement jumps (CMJs) and squat jumps (SJs) on a force platform in a double-blind, counterbalanced, randomized, crossover design. Participants ingested a placebo or 1, 3, or 6 mg/kg caffeine 60 min before jumps. Jump heights were calculated by the velocity at jump takeoff using impulse and body mass, given from ground reaction force. Comparisons of jump performance among conditions were performed with one-way repeated-measures ANOVA and a paired Student's t-test with a Bonferroni correction. Relationships between jump height changes in each caffeine dose and interindividual factors were analyzed by the Spearman correlation test.

RESULTS: Compared with the placebo, 6 mg/kg caffeine significantly enhanced CMJ ($P < 0.001$) and SJ ($P = 0.012$) heights; moreover, 1 and 3 mg/kg caffeine significantly increased CMJ height (both $P < 0.01$) but not SJ height (both $P > 0.05$). There were no significant differences among all caffeine doses in both jumps (all $P > 0.05$). Furthermore, ergogenic effects of any caffeine dose on jump heights did not relate to plasma caffeine concentration immediately after jumps and habitual caffeine intake significantly (all $P > 0.05$). However, the ergogenic effects of 1 and 3 mg·kg-1 caffeine were negatively associated with jump height at the placebo condition (i.e., baseline performance level) in both CMJ (1 mg/kg: $\rho = -0.46$, 3 mg/kg: $\rho = -0.44$, both $P < 0.05$) and SJ (1 mg/kg: $\rho = -0.55$, 3 mg/kg: $\rho = -0.53$, both $P < 0.01$), whereas 6 mg/kg caffeine was not (both $P > 0.05$).

CONCLUSION: Even at a dose as low as 1 mg/kg, caffeine improved vertical jump performance in a dose-independent manner. Additionally, these enhancements were independent of plasma caffeine concentration and habitual caffeine intake. However, the ergogenic effects of lower dose caffeine were dependent on athletes' baseline performance. This study is the first to show the ergogenicity of 1 mg/kg caffeine on jump performance and provides new insight into the safe and effective ergogenic strategy in sports science.

ACUTE CAFFEINE AND SODIUM BICARBONATE CO-INGESTION DOES NOT CAUSE A SUMMATIVE EFFECT ON MUSCULAR ENDURANCE ACCORDING TO MUSCLE SIZE GROUP

MUNILLA, C.1, MONTALVO-ALONSO, J.J.1, GARRIGA-ALONSO, L.1, VALADÉS, D.1, FERRAGUT, C.1, PÉREZ-LÓPEZ, A.1

1. UNIVERSIDAD DE ALCALÁ

INTRODUCTION: There is a consensus that caffeine (CAF) and sodium bicarbonate (NaHCO3) are sports supplements that, ingested isolated, attenuate and delay fatigue appearance, by improving Ca2+ bioavailability and reducing acidosis, respectively. In muscular endurance performance, both supplements also seem to promote an increase in performance by extending muscle contraction in time and delaying the force production decrement observed in extenuating tasks. However, while the effect of NaHCO3 on muscular endurance is irrespective of muscle size group, CAF ergogenic effect seems to be higher in large compared to small muscle groups due to increased motor unit recruitment and firing rates. Therefore, this study aimed to examine the effect of the acute co-ingestion of CAF and NaHCO3 in upper- and lower-body on muscular endurance performance.

METHODS: Twenty-seven recreationally resistance-trained individuals (male/female: 14/13; age: 24±3 yr; body mass: 69.4±14.1 kg) participated in a double-blind, placebo-controlled, cross-over and randomized study. Participants were assigned to four conditions: a) NaHCO3+CAF; b) NaHCO3; c) CAF; d) placebo (PLA). Participants ingested 0.3 g/kg of body mass of either NaHCO3 or placebo on two occasions at 120 and 90 min before the trial, consuming 0.15 g/kg of body mass each time. Subsequently, 60 minutes before the trial, participants ingested 3 mg/kg body mass of either caffeine or placebo. Then, participants performed two muscle endurance tests of bench press and back squat exercises at 65% and 85% 1RM, performing as many repetitions as possible in one serie until task failure.

RESULTS: No differences in body composition or dietary intake were found among experimental conditions. Compared to PLA, CAF supplementation improved the number of repetitions (ANOVA effect, P<0.001), mean velocity (ANOVA effect, P=0.043) and mean power (ANOVA effect, P=0.026). CAF ingestion stimulates these effects mainly in the squat exercise, particularly at 85% 1RM for mean velocity (4.7%, P = 0.033), peak velocity (4.6%, P=0.034), mean power output (5.5%, P=0.022), peak power output (7.1%, P=0.023) and force peak (2%, P=0.044) compared to placebo. NaHCO3 and NaHCO3+CAF did not report any statistically significant difference compared to the placebo for any investigated variables.

CONCLUSION: In conclusion, co-ingestion of caffeine and sodium bicarbonate did not promote a synergic effect on muscle endurance performance. Only acute caffeine intake stimulated an improvement in back squat exercise performance, particularly at 85%1RM. This effect on caffeine larger but not in smaller muscle groups (quadriceps vs deltoids) reinforces the central hypothesis suggesting that this substance mechanism of action mainly occurs in the central nervous system. However, this effect can be attenuated when ingested together with NaHCO3, suggesting that this supplement may alter the pharmacokinetics and pharmacodynamics of caffeine.

EFFECT OF ACUTE SODIUM BICARBONATE AND CAFFEINE INGESTION ON HIGH-INTENSITY SPRINT PERFORMANCE

GARRIGA-ALONSO, L.1, FERRAGUT, C.1, GONZALO-ENCABO, P.1, LÓPEZ-SAMANES, A.2, VALADÉS, D.1, PÉREZ-LÓPEZ, A.1

1.UNIVERSITY OF ALCALÁ 2.UNIVERSITY OF FRANCISCO DE VITORIA

INTRODUCTION: Caffeine (CAF) and sodium bicarbonate (NaHCO3) are two supplements that provide sports performance-enhancing effects. The acute and isolated ingestion of both supplements improves high-intensity tasks that last between 30 s to 10 min. CAF and NaHCO3 improve Ca2+ utilization in skeletal muscle by increasing its bioavailability and reducing acidosis, respectively. Thus, it can be argued that the co-ingestion of both supplements may produce a summative ergogenic effect on high-intensity exercise. However, this idea has been scarcely studied. Therefore, this study aimed to examine the effect of the acute co-ingestion of CAF and NaHCO3 on high-intensity sprint performance.

METHODS: Twenty-five recreationally-trained individuals (age: 23.3±4.0 years; sex (female/male): 12/13; body mass: 69.6±12.5 kg) participated in this randomized, double-blind, placebo-controlled and cross-over study design. Participants were assigned to four conditions: a) NaHCO3+CAF; b) NaHCO3; c) CAF; d) placebo (PLA). Participants ingested 0.3 g/kg of body mass of either NaHCO3 or placebo on two occasions at 120 and 90 min before the trial, consuming 0.15 g/kg of body mass each time. Subsequently, 60 min before the trial, participants ingested 3 mg/kg body mass of either caffeine or placebo. Then, participants performed four Wingate tests (Wt), interspersed by 1.5 min rest period among them, each one consisting of a 30-s all-out sprint against an individualized resisted-load (7.5% participants' body mass). Before and immediately after the Wt capillary blood samples were collected for lactate assessment.

RESULTS: Peak (Wpeak) and mean (Wmean) power output revealed a supplement (ANOVA, P=0.029 and 0.040) and supplement and sprint interaction effect (ANOVA, P=0.009 and 0.049). Compared to the placebo, NaHCO3+CAF and NaHCO3 increase Wpeak performance in Wt3 and Wt4 (3-7%, P<0.05). While NaHCO3 supplementation increased Wmean performance in Wt3 (4.2%, P=0.001). Time to Wpeak and fatigue index (FI) did not report statistically significant supplement or interaction effects. However, both variables, time to Wpeak (-6.7 to -10.3%) and FI (5.4 to 9.3%) reported partial differences in all supplement protocols compared to placebo (P<0.05). Finally, lactate showed a supplement plus sprint interaction (ANOVA, P<0.001). Differences were found immediately after the Wt4, when comparing CAF+NaHCO3 and NaHCO3 to caffeine (13-17%, P<0.05) and placebo (23-28%, P<0.05).

CONCLUSION: Although the isolated ingestion of caffeine and sodium bicarbonate improved high-intensity sprint performance, the co-ingestion of both supplements did not stimulate a summative ergogenic effect. Therefore, despite the

potential existence of any pharmacokinetic and pharmacodynamic interaction between caffeine and sodium bicarbonate, in skeletal muscle, the potential ergogenic effect of both supplements on Ca2+ bioavailability and utilization seem not to be synergic.

LOW- VS HIGH-CARBOHYDRATE DIET ON CONTINUOUS GLUCOSE MONITORING METRICS AND PERFORMANCE IN COMPETITIVE CYCLISTS: A RANDOMIZED CROSSOVER TRIAL

AMATORI, S.1, RADICE, R.1, PODLOGAR, T.2, GOBBI, E.1, BERTUCCIOLI, A.1, SUDANO, M.1, SISTI, D.1, ROCCHI, M.B.L.1, PERRONI, F.1

1 DEPARTMENT OF BIOMOLECULAR SCIENCES, UNIVERSITY OF URBINO CARLO BO, URBINO, ITALY; 2 SCHOOL OF SPORT, EXERCISE AND REHABILITATION SCIENCES, UNIVERSITY OF BIRMINGHAM, BIRMINGHAM, UK

INTRODUCTION: Continuous glucose monitors (CGM) recording minute-by-minute interstitial glucose levels have recently gained popularity among professional endurance athletes for their purported benefits of monitoring and optimizing fueling adequacy around training sessions and competitions, as carbohydrate intakes between and within days are usually arranged according to the goal and the fuel requirements of each training session (1). While GCM use is supported by evidence among active and non-active diabetes patients, data on healthy athletes is still very limited (2). This study aimed to examine the glycemic responses to a short-term low-carbohydrate or high-carbohydrate diet in healthy competitive cyclists while wearing a CGM.

METHODS: This randomized crossover-designed study recruited 13 competitive cyclists with more than 8 hours of training per week (29±10 years, 174±7 cm, 70±9 kg, 309±42 WCP). Participants were asked to follow a 3-day standard run-in diet, followed by 7 days of either a low-carbohydrate (<130 g/day) or high-carbohydrate diet (> 5 g/kg/day) in a randomized order, while a CGM (Abbott Libre Sense) measured their interstitial glucose for 14 consecutive days. On the last day of each diet period, participants underwent a 3-hour training session, including two 3-minute all-out intervals at the start and at the end of the session, and power data was recorded. Glucose data was divided into sleep and wake phases and analyzed using the iglu Shiny app. Mean glucose levels, coefficient of variation (CV), and mean amplitude of glycemic excursion (MAGE) metrics were considered as main outcome variables. A MANOVA for repeated measures was conducted to test differences between diet periods.

RESULTS: When analyzing the treatment (diet) effect, no significant variations were reported for any of the collected variables, neither during sleep nor wake time (all $p \geq 0.05$). A different glucose distribution over time in the zones (<70, 70120 mg/dL) was reported, with the high-CHO period showing a wider distribution in the three zones. When participants consumed the diet high in carbohydrates, average power was higher in both 3-minute intervals (+5.9±5.5%, $p<0.01$), and there was a smaller decrease in power output between the initial and final burst (-5.1±4.5%, $p=0.003$) compared to the low-carbohydrate week (-6.6±5.1%, $p=0.002$).

CONCLUSION: While CGM may provide a fast and an easy snapshot of interstitial glucose levels, in this study glucose metrics seemed to not be influenced by diet in healthy competitive cyclists. However, performance during the 3-min bout was worse in the low-CHO period, as well as the within session power decrement. The usefulness of this technology for optimizing off- and on-the-bike fueling strategies to improve training adaptations and performance remains to be determined and requires further investigation.

RELATIONSHIP BETWEEN BLOOD GLUCOSE CONCENTRATION AND RUNNING PERFORMANCE DURING HALF-MARATHON RACE IN WELL-TRAINED DISTANCE RUNNERS

TANJI, F.

TOKAI UNIVERSITY

INTRODUCTION: Well-trained distance runners exercise at an intensity of >80% of maximal oxygen uptake during half-marathon running. Carbohydrates are the primary energy source during intense-intensity running. During the half-marathon race, runners almost not be stuck by a sudden feeling of exhaustion described as "hitting the wall", due to a lack of glycogen stores or absence of suitable energy source. Consuming more carbohydrates is considered to have a positive effect on half-marathon running performance. Blood glucose concentration (BGC) during high-intensity cycling exercise is shown to be higher in well-trained cyclists than in untrained cyclists (Coggan et al., 1995; Kjaer et al., 1986). Therefore, we aimed to clarify the relationship between BGC during half-marathon race and running performance by continually measuring BGC during the race.

METHODS: Fourteen well-trained male distance runners, with a mean seasonal best time of 29:40.0±37.5 for 10,000 m, competed in an official half-marathon race. In all runners, BGC was continuously monitored every 15 min from 24 hours before the race to the end of the race using a glucose monitor system (FreeStyle Libre, Abbott Japan, Japan). Analyses used BGC 5 h before the race (Gpre), peak BGC during the half-marathon race (Gpeak), and mean BGC during the race (Gmean). Additionally, mean running speed during the half-marathon (sHM) and difference in running speed between the first 5 km and the last 6 km of the half-marathon (Δspeed) were calculated as running performance variables. Pearson's

correlation coefficient was used to assess the relationship between BGC and running performance variables. The significance was set at a P value of <0.05.

RESULTS: Mean Gpre, Gpeak, and Gmean were 87.8 ± 13.5, 191.4 ± 53.2, and 167.8 ± 43.8 mg/dL, respectively. The half-marathon finish time and sHM were 66:03 ± 2:45 and 320 ± 13 m/min, respectively. The Δspeed was 22 ± 23 m/min. The Gpeak and Gmean were significantly associated with sHM (r = 0.69 and 0.75, respectively; P < 0.05) and Δspeed (r = −0.67 and −0.73, respectively; P < 0.05).

CONCLUSION: Runners maintaining a high BGC during the half-marathon race had a superior running performance. Furthermore, running speed in the second half of the race decreased more in runners with lower BGC than in those with higher BGC. These results suggest that continuous BGC monitoring and maintaining a high BGC might contribute to superior half-marathon performance.

DYNAMICS OF GUT MICROBIOTA DURING A CYCLING GRAND TOUR IS RELATED TO EXERCISE PERFORMANCE AND MODULATED BY DIETARY INTAKE

FERNÁNDEZ, M., FERNÁNDEZ, J., MARTÍNEZ, P., RODRÍGUEZ-ALONSO, M., ORTOLANO, R., PINTO, P., CASTILLA, J., COTO, A., RUIZ, L., VILLAR, C.J., TOMÁS, C., MARGOLLES, A., FERNÁNDEZ, B., IGLESIAS, E.

UNIVERSITY OF OVIEDO

Lombó, F.

INTRODUCTION: Regular exercise has been described as a factor modifying both the diversity and the relative abundance of certain bacterial phyla or families, although the few studies that have been carried out on this show important methodological differences and divergent results. To our knowledge, the effect of a cycling stage race on the gut microbiota composition and metabolic activity of professional cyclists has not been analysed. Studying the composition of the intestinal microbiota in this context can help both to understand its potential modulatory role in the response to exercise and to optimize and personalize the use of supplements. The aim of this cohort study was to analyse the dynamics of faecal microbiota composition of professional cyclists over a Grand Tour, and their relationship with performance and dietary intake.

METHODS: 16 professional cyclists competing in La Vuelta 2019 were recruited. Faecal samples were collected at four time points: The day before the first stage (A); After 9 stages (B); After 15 stages (C); On the last stage (D). Faecal microbiota populations were analysed using 16S rRNA sequencing. Dietary intake before and during La Vuelta 2019 was recorded by means of semiquantitative food frequency questionnaires.

RESULTS: A principal component analysis (PCA) followed by Generalized Estimating Equation (GEE) models were carried out to explore the dynamics of microbiota and its relationship with performance. Bifidobacteriaceae, Coriobacteriaceae, Erysipelotrichaceae, and Sutterellaceae dynamics showed a strong final performance predictive value (R2=0.83, ranking and R2=0.81, accumulated time). The abundance of Erysipelotrichaceae at the beginning of La Vuelta was directly related to the previous intake of a complex-carbohydrate-rich foods, while during the competition the abundance of Bifidobacteriaceae was negatively affected by the intake of simple carbohydrates from supplements.

CONCLUSION: An ecological perspective represents more realistically the relationship between gut microbiota composition and performance, compared to single-taxon approaches. The composition and periodisation of diet and supplementation during a Grand Tour, particularly carbohydrates, could be designed to modulate gut microbiota composition that allow better performance.

COMPARISON OF SLEEP HEART RATE VARIABILITY MEASURED WITH THE OURA® RING TO A CONVENTIONAL MORNING MEASUREMENT WITH A HEART RATE MONITOR

MORIN, F.1, JEKER, D.1, GOULET, E.D.B.2, BIEUZEN, F.1

1. INSTITUT NATIONAL DU SPORT DU QUÉBEC; 2. UNIVERSITÉ DE SHERBROOKE

INTRODUCTION: Resting heart rate variability (HRV) is a non-invasive measure of the autonomic regulation of the myocardium; it can be used to monitor the response to training. The most common practice is to measure HRV upon awakening. Devices measuring HRV throughout the night are now available. They may contribute to improving measurement assiduity, an important factor for valid tracking (1). The aims off this study were to: 1) Compare sleep HRV measured with the OURA® ring (Oura Health Oy, Finland) during the night to a morning measurement at rest with a conventional heart rate monitor. 2) Examine the relation between acute:chronic workload ratio (ACWR) and the HRV measured with both methods.

METHODS: During a 3-week training period, 14 female soccer players (15-16 years) wore the OURA® ring during sleep and were instructed to record their post-awakening morning HRV with a commercial heart rate monitor (polar H10, Polar Electro Oy, Finland) paired to a mobile app (Elite HRV, USA). In parallel, they recorded the duration and rating of perceived exertion (RPE) of every training session with an athlete monitoring system (XPS Network®, Sideline Sports, USA) to obtain a daily session-RPE (sRPE). The ring computes the root mean square of the differences between successive heartbeats (RMSSD) for every 5-min of continuous sleep throughout the entire night. The mobile app paired to the heart rate monitor was set to record heart rate for 3-min supine. The first minute was used as a stabilization period and only the last 2-min were used for analysis (2). The average of all 5-min recording at night was compared to the 2-min supine morning recording. For ACWR, a 7-day and a 28-day exponentially weighed moving average of sRPE was used to calculate acute and chronic fatigue (3). Relation between ACWR and each HRV methods were assessed using mixed effects models. Athletes with fewer than 3-weekly measurements for either method were excluded from the evaluation of the relationship with ACWR (1).

RESULTS: Throughout the 3-week period, compliance was greater for the ring with 81% vs 56% for the morning measurement ($P = 0.002$). No difference was observed between methods ($P = 0.886$) with an average RMSSD of 82.2 ± 43.4 ms and 78.5 ± 38.9 ms for the morning and the ring measurements respectively. The mean bias between measurement methods for RMSSD was 3.7 ms and the limits of agreements were -91.9 to 99.2 ms. A relationship was observed between nighttime RMSSD and ACWR ($P = 0.038$; $n = 152$) whereas it was not the case between morning RMSSD and ACWR ($P = 0.3$; $n = 137$).

CONCLUSION: As HRV measurement with the OURA® ring was related to the athletes' ACWR and a better adherence towards its use was observed, our results suggest that the monitoring of HRV with the ring may be a preferable alternative to the conventional method.

AI-SMARTPHONE MARKERLESS MOTION CAPTURING OF COUNTER-MOVEMENT-JUMP KINEMATICS

BARZYK, P., ZIMMERMANN, P., STEIN, M., GRUBER, M.

UNIVERSITY OF KONSTANZ: UNIVERSITAT KONSTANZ

INTRODUCTION: A motion capture technology that comes at a low cost and requires no additional hardware could act as a game changer that allows assessing kinematic data in field studies (1). In the present study, we developed and validated a novel markerless, smartphone video-based artificial intelligence (AI) motion capture system that utilizes deep learning techniques to calculate and analyze body movements. The novel system estimates 3D kinematics from 2D video sequences and can thus detect and analyze e.g. movement in the sagittal plane from a frontal view. We validated the system by obtaining and comparing lower limb counter-movement-jump (CMJ) kinematics to those of a gold-standard method.

METHODS: Thirteen participants (1 female), age 28 (± 9) years performed six CMJs. We used 2D videos created by a smartphone (Apple iPhone X, 4K, 30 fps), mounted on a tripod, and placed in front of the participants to create 18 different key points which together build a full skeleton including joints and their connections. The key point locations are estimated in 2D pixel coordinates and create a 360° pose estimation and resulting joint angles (flexion and extension). Body parts and skeletal key points are recognized and localized by calculating confidence maps using a multi-level Convolutional Neural Network that integrates both spatial and temporal features and does not require any additional sensors or hardware (2). We evaluated and validated the angular response over the entire movement against a gold standard Vicon motion capture system using Pearson's r correlation coefficients as well as the Mean Average Error (MAE) and Mean Squared Error (MSE).

RESULTS: Pearson correlation coefficients (r) for shoulder, hip, and knee angular progressions in the sagittal plane during the entire movement were reported as .97, .99, and .99, respectively. MAE was calculated in degrees and reported as 3.18 for the shoulder, 2.24 for the hip, and 2.18 for the knee angle. MSE was 2.85 for the shoulder, 2.62 for the hip, and 2.85 for the knee angle respectively.

CONCLUSION: The results showed that the smartphone AI motion capture system achieved both high validity and high accuracy, indicating that it is a viable alternative to traditional motion capture systems which can accurately track human movement and provide valid joint angle data. Nevertheless, it still has to be determined whether the system can correctly measure more complex 3D movements, such as rotational movements, or if it can detect deformations like Varus or Valgus knee alignment.

INDIVIDUALIZING HIGH-INTENSITY INTERVAL TRAINING INTENSITY IN DISTANCE RUNNERS: ARE PEAK TREADMILL SPEED AND 10000-M SPEED PERCENTAGES VALID ALTERNATIVES TO THE DELTA CONCEPT?

MAZZOLARI, R.1,2, VILLANOVA, S.3, CASADO, A.4, MORENO-PÉREZ, D.5, HECKSTEDEN, A.1, SANTOS-CONCEJERO, J.2, PORCELLI, S.6

1UNIVERSITÄT INNSBRUCK; 2UNIVERSITY OF THE BASQUE COUNTRY; 3UNIVERSITY OF THE WEST OF SCOTLAND; 4REY JUAN CARLOS UNIVERSITY; 5COMILLAS PONTIFICAL UNIVERSITY; 6UNIVERSITY OF PAVIA

INTRODUCTION: Cardiorespiratory adaptations to high-intensity interval training (HIIT) are optimized when athletes train longer at (or near) maximal oxygen uptake (1). Previous research showed that the speed (vΔ50) halfway between the second lactate threshold (vLT2) and the peak treadmill speed (Vpeak) identifies an optimal intensity for inducing cardiorespiratory adaptations to exercise in distance runners (2). Since most runners cannot access human physiology laboratory testing due to high costs and time restrictions, there is a need for valid, cheap and practical alternatives to the Delta concept for individualizing HIIT prescriptions. Previous studies showed that vΔ50 corresponds to about 90% of Vpeak with very low individual variability (2-4). Moreover, 10000-m races are run at intensities that are, on average, close to vΔ50 (5). Therefore, we investigated whether the respective percentages of Vpeak and 10000-m speed can be considered valuable candidates to prescribe HIIT to distance runners instead of vΔ50.

METHODS: Sample size planning was aimed at accuracy in parameter estimation (6). 75 distance runners (58 men and 17 women, age: 37 ± 8 years old) were recruited for the study. 57 (for Vpeak) and 61 (for 10000-m speed) runners underwent replicated measurements after 8 weeks. Blood lactate from the earlobe and cardiopulmonary variables were determined during a discontinuous incremental stepwise test on the treadmill (3-min step duration, 1.5 km/h speed increase, 1% gradient). vLT2 was determined using the modified Dmax method (7), and Vpeak was derived using linear interpolation (8). 10000-m performance was tested on a 400-m track. The percentage of Vpeak and 10000-m speed corresponding to vΔ50 was then determined. Moreover, we performed inferential analysis using mixed-effects models to isolate the net interindividual variability from the other sources of variability (9). We presented the results as mean ± standard deviation (SD) or point estimate and 95% confidence interval (CI).

RESULTS: vLT2, Vpeak and 10000-m speed in the 75 runners were 14.2 ± 1.1, 17.0 ± 1.3, and 14.2 ± 1.2 km/h, respectively. vΔ50 occurred at 91.7% (95% CI: 91.3 to 92.1) of the Vpeak with a SD of 1.5% (95% CI: 1.3 to 1.8) and 110.2% (95% CI: 109.0 to 111.5) of the 10000-m speed with a SD of 5.2% (95% CI: 4.5 to 6.3), respectively. The net interindividual variability for Vpeak and 10000-m speed percentage corresponding to vΔ50 was 1.0% (95% CI: 0.7 to 1.5) and 4.2% (95% CI: 3.2 to 6.2), respectively.

CONCLUSION: Vpeak but not 10000-m speed percentages can be a valid alternative to the Delta concept for individualizing HIIT intensity in distance runners and have the potential to make this HIIT approach more accessible to the largest part of the runner population.

EFFECTS OF HEAVY RESISTANCE VS PLYOMETRIC TRAINING ON RUNNING ECONOMY AND RUNNING TIME TRIAL PERFORMANCE IN MIDDLE-AGED RECREATIONAL RUNNERS: A RANDOMIZED CONTROLLED TRIAL

EIHARA, Y., TAKAO, K., SUGIYAMA, T., MAEO, S., KANEHISA, H., ISAKA, T.

RITSUMEIKAN UNIVERSITY

INTRODUCTION: Running economy has a critical role in long-distance running performance [1]. Heavy resistance training (HRT) and plyometric training (PT), as an adjunct to running training, could improve running economy and running time trial performance [2]. However, the comparative effectiveness is unknown, especially in middle-aged recreational runners despite their increasing number [3]. Elucidating effective training modalities for improving long-distance running performance will provide useful information in designing training programs for middle-aged recreational runners. Thus, the present study examined the effects of HRT versus PT, as an adjunct to running training, on long-distance running performance in middle-aged recreational runners.

METHODS: Twenty middle-aged recreational runners were randomly allocated into HRT or PT group (n = 10/group). Participants conducted prescribed training programs twice a week for 10 weeks as an adjunct to daily running training. HRT program consisted of leg press, leg curl, and calf raise with 50–90% of one repetition maximum (1RM), taking 2 seconds for each concentric and eccentric phase. PT program included counter-movement jump (CMJ), rebound jump, hurdle hop, and drop jump as quickly as possible. Before and after the intervention, the participants were tested for 1RM of the three lifting tasks (leg press, leg curl, and calf raise), jump performance (CMJ and drop jump performances), VO2 at 8–12 km/h (running economy), VO2max, velocity of VO2max (vVO2max), and 5-km running time.

RESULTS: HRT significantly increased 1RM of the three lifting tasks (19.1–21.1%, $p < 0.001$), while PT significantly enhanced the 1RM of leg curl only (8.3%, $p = 0.007$). Both HRT and PT significantly enhanced the scores of CMJ (6.4–8.3%, $p = 0.016$) and drop jump (9.3–26.2%, $p = 0.005$–0.009) without significant differences in the gains between the groups ($p \geq 0.248$). No significant main effects and group-by-time interactions were detected in running economy (-2.6–-1.1%; $p \geq 0.271$), VO2max (-0.11–0.64%; $p \geq 0.598$), and vVO2max (0.7–2.0%; $p \geq 0.233$). There were also no significant main effects and interactions in 5-km running time (-0.2–0.8%; $p \geq 0.491$). The individual variance of the improvement in running economy was negatively correlated with those of the baseline 1RM, jump performances, and VO2max ($r = -0.872$–-0.582, $p =$

0.001–0.078) in PT, suggesting that the effect of PT on running economy is influenced by muscle strength, jump abilities, and VO2max at baseline.

CONCLUSION: In middle-aged recreational runners, the addition of HRT or PT to running training can increase muscle strength and/or jump performance, but neither of these has a significant effect on long-distance running performance. Nevertheless, runners with higher 1RM, jump performances, and VO2max at baseline may better improve running performance by conducting PT.

EFFECT OF ATTENTIONAL FOCUS STRATEGY ON DROP JUMP PERFORMANCE, KINETICS AND KINEMATICS : COMPARISON BY DJ EXPERIENCE LEVEL

FURUHASHI, Y.1, MURATOMI, K.1, YOSHIDA, T.2, TANIGAWA, S.1, MAEMURA, H.1

1 UNIVERSITY OF TSUKUBA , 2 JAPAN INSTITUTE OF SPORTS SCIENCES

INTRODUCTION: Attentional focus strategy (AFS) can promote a neutral (NEU), internal (INT), or external focus of attention (EXT) and improves various sports performance. Drop jump (DJ) is a plyometric training that strengthens the stretch-shortening cycle in lower limb muscles and is commonly utilized by strength and conditioning coaches and athletes. Furuhashi et al. 1) reported that EXT improves DJ performance in inexperienced DJ. Another study suggested that modifying the instructions for AFS in inexperienced DJ can reduce contact time (CT) and increase jump height (JH) 2). Thus, it is clear that AFS can be effective coaching method in DJ. However, all of these have been limited to effects on DJ performance. Hence, this study aimed to investigate the effects of AFS on DJ, focusing on both performance and the kinetics and kinematics involved.

METHODS: 19 experienced DJ male athletes (E group) and 10 inexperienced DJ healthy male collegiate (I group) performed two trials of DJ each under three conditions (NEU, INT, and EXT). The instructions for each condition were as follows: Neutral: "Perform the jump to the best of your ability", Internal: "Step off the box, land on the balls of your feet, then fully and explosively extend your ankles, knees, and hips to jump as high as possible", External: "Step off the box, jump fast, imagine the ground is hot, get off the ground quickly, imagine you are a stiff spring, and focus on jumping to the roof." Three-dimensional coordinates of the 47 retroreflective markers fixed on each subject's body were obtained using a Vicon T20 system (Vicon Motion Systems Ltd.) with 10 cameras operating at 250 Hz. Ground reaction force was measured by a force platform at a rate of 1000 Hz. From the measured data, reactive strength index (RSI), contact time, jump height, kvert, joint torque, joint torque power, angular flexion, and extension displacements of the lower leg joints were calculated.

RESULTS: The E Group showed the highest DJ performance in NEUT. Additionally, there were significant differences between conditions in kinematics and kinematics in a few variables.

The I group showed the highest DJ performance in NEUT and EXT. In addition, there were significant differences between conditions in many variables in kinetics and kinematics.

CONCLUSION: The results suggest that the optimal AFS depends on the degree of DJ experience. The findings also suggest that AFS has a greater effect on kinetics and kinematics in DJ inexperienced individuals compared to DJ experienced.

IMPACT OF PRE-SEASON TRAINING ON CORE STABILITY, PERFORMANCE AND INJURY RISK IN FOOTBALL

WEBER, T.A., DUCHENE, Y., SIMON, F.R., MORNIEUX, G., GAUCHARD, G.C.

UNIVERSITY OF LORRAINE

INTRODUCTION: Core Stability is defined as the ability to control the position and motion of the trunk over the pelvis to allow optimum force transmission to the terminal segments [1]. Core training improves sprinting and shooting performance [2,3] and decreases ACL injury risk by stabilizing the trunk over lower limbs [3]. However, the link between the Core Stability, measured on the field, and the performance is not clear. Thus, the aim of this study was to determine the effect of pre-season training on Core Stability and its link with ACL injury risk and performance.

METHODS: Thirty-five soccer players from U17 and U19 teams performed two measure sessions, before (T0) and after (T1) typical soccer pre-season training. Core Stability was assessed by Close Kinetic Chain Lower Extremity Stability Test (CKCLEST) score (highest number of touches in 15 seconds) and by the composite score (sum of the best score of each axis, normalized against participants' leg length) for Lower Quarter Y Balance Test (LQ-YBT). To evaluate the ACL injury risk, they performed 6 non-anticipated cutting tasks filmed by two video cameras (Hero 7, GoPro, USA) placed in sagittal and frontal planes. The Cutting Movement Assessment Tool (CMAS) was used to estimate the ACL injury risk from 0 (no risk) to 11 (very high risk). Cutting was followed by a shot from the penalty point. Ball peak speed was measured with a radar (Stalker Pro II, Stalker Sport, USA). Paired sample Student's t-test was used to compare the two sessions and effect size was computed by Cohen's d. Significance was set at $p<0.05$.

RESULTS: Significant improvement was found for CKCLEST score ($p < 0.001$, $d = 1.73$) between T0 and T1 (24.2 ± 2.7 vs. 28.4 ± 2.8 touches) but LQ-YBT composite score showed no significant differences ($p = 0.307$, $d = 0.18$) with 108.5 ± 5.7 vs. 109.4 ± 5.3 cm for T0 and T1, respectively. CMAS means were 4.04 ± 0.77 (T0) vs. 3.72 ± 0.79 (T1) without significant differences ($p = 0.065$, $d = 0.333$). Shooting speed was not significantly different ($p = 0.146$, $d = 0.259$) between the two sessions (25.2 ± 2.3 (T0) vs. 25.8 ± 1.7 (T1) m.s-1).

CONCLUSION: The increase of CKCLEST score between sessions shows that pre-season training influence Core Stability by improving speed of lower limb combined to a better trunk and pelvis stability. However, shooting, which induces the same kind of movement (i.e. leg dynamic movement in sagittal plane with core stability) was not improved by pre-season training. In addition, football pre-season training, generally composed by prone plank exercises [5], in unlikely to improve motor control of the core, as evaluate by LQ-YBT. Beyond the importance to assess Core Stability with dynamic test, it will be interesting to integrate dynamic core exercises to pre-season training to increase performance and injury risk along with Core Stability.

MODELLING OF LACTATE-TIME CURVES FOR ESTIMATING PERFORMANCE PARAMETERS IN CYCLING

SCHÄFER, R., SUTTMEYER, J., VENZKE, J., REUTER, Y., DMITRIEVA, A., PLATEN, P.

RUHR UNIVERSITY BOCHUM

INTRODUCTION: Lactate power curves from graded exercise tests are commonly used to derive performance markers and intensity domains in endurance sports. These curves can differ between testing protocols because the time course is neglected. Mader (2003) described a metabolic model consisting of four differential equations which naturally describe the blood lactate response over time in response to exercise. In practice, this model is already used to infer performance markers such as maximal oxygen consumption (VO2max) and maximal lactate accumulation rate (ċLamax) from observed lactate testing data but an evaluation is still lacking. In this study, we evaluated the computational properties of this approach in silico. Further, we compare estimates from this approach against measured performance markers in a case study.

METHODS: The metabolic model from Mader was adopted as described by Heck et al. (2022) to estimate VO2max and ċLamax based on lactate-time curves of graded exercise tests. We simulated lactate responses to a graded exercise test (50 Watt increase every 5 minutes) with varying VO2max and ċLamax. Next, random noise with varying levels was applied to hypothetical measurements at the end of each stage to reflect measurement error. VO2max and ċLamax were obtained by nonlinear least-squares estimation using the Levenberg-Marquart algorithm. In a case study, VO2max and ċLamax were obtained from a ramp test and a sprint test, respectively. Lactate measurements from a graded exercise tests (increment 40W/5min) were used to estimate VO2max and ċLamax using least squares and Markov Chain Monte Carlo (MCMC) methods to obtain the posterior distribution using slightly informative priors.

RESULTS: The computer simulation showed larger estimation errors and worse parameter recovery within confidence intervals for ċLamax than for VO2max. With high error (SD = 0.4), the algorithm failed to estimate any parameter in less than 0.7 % and parameter coverage decreased for VO2max (91.8-99.9%) and ċLamax (87.5-99.9%) compared to low error (SD = 0.1, 100%). Moderate error (SD = 0.2) yielded estimates within ~5% of the original VO2max and ~35% of ċLamax in 95% of the simulation.

In the case study, measured VO2max and ċLamax were 61 ml/min/kg and 0.59 mmol/min/l, respectively. Least squares estimation yielded a VO2max of 60.3 CI95% [57.5; 63.1] and ċLamax of 0.63 CI95% [0.35; 0.91]. Estimation via MCMC yielded a VO2max of 59.5 CI95% [57.6; 61.3] and ċLamax of 0.56 CI95% [0.41; 0.73].

CONCLUSION: Non-linear least squares estimation yields robust estimates of VO2max but was more uncertain for ċLamax. The case study showed small differences between estimated and measured VO2max and ċLamax. Additional test data (e.g., sprint tests) could be used to possibly enhance parameter estimation. Thus, a principled method for learning performance parameters from observed testing data using a theoretical model is presented. The validity of this approach has still to be proven.

THE RELATIONSHIP BETWEEN BREATHS TAKEN AND SWIMMING PERFORMANCE IN A 50-METER FREESTYLE RACE

MATSUNAMI, M., SUITO, H., FUNAI, Y., TAIMURA, A.

ST. CATHERINE UNIVERSITY, MIE UNIVERSITY, KUMAMOTO GAKUEN UNIVERSITY, NAGASAKI UNIVERSITY

INTRODUCTION: The 50m freestyle race is the event with the highest speed in the competitive swimming. To achieve a high swimming speed, the following are important, (1) increase propulsion and (2) minimize resistance (Toussaint & Beek, 1992). The front crawl stroke used in racing is considered to cause an increase in resistance and a reduction in propulsion, as the posture changes significantly due to respiratory movements (Pedersen et al., 2006). Further, it has been shown that it is necessary to reduce the number of breaths to as few as possible to avoid increasing the resistance in the 50m freestyle races (Pedersen et al., 2006). However, how many breaths should be taken during a 50m freestyle race was not indicated. The purpose of this study was to examine the relationship between the number of breaths during a race and the swimming performance results in a 50m freestyle event.

METHODS: 228 swimmers (121 males, 107 females) who participated in the 50m freestyle event at the Inter college swimming championship 2018 in Japan were analyzed. The competition was carried out at a long course (50m). Each race in the heats and B-final, and the final competition was video-recorded, and the number of breaths of the subjects was counted from the obtained movie. The swimming speed was calculated from the competition results and used as the swimming performance.

RESULTS: In the 50m freestyle races, the most frequently observed number of breaths was once (44.2%) in males and three times (32.0%) in females. The average number of breaths was 1.3 times for males and 3.0 times for females in the heat and was 0.3 times for males and 1.8 times for females in the finals. There was a significant difference between the heat and the finals in the number of breaths for both males and females ($P<0.05$). The swimming speed at each the number of breaths for males and females, respectively, was 2.147 m/s and 1.921 m/s in 0 time, 2.108 m/s and 1.882 m/s in 1 time, 2.085m/s and 1.878 m/s in 2 times, 2.058 m/s and 1.846 m/s, in 3 times, 2.046 m/s and 1.821 m/s in 4 times, and 2.177 m/s and 1.818 m/s in 5 times. In addition, for females, it was 1.818 m/s in 6 times and 1.778 m/s in 8 times. A significant difference was observed in the swimming speed at each the number of breaths ($P<0.05$). There was a significant correlation between the number of breaths and the swimming speed in male and female ($P<0.05$)

CONCLUSION: Previous studies have reported that eight male 50m freestyle finalists in the national championships breathed 1, 2 or 3 times (Pedersen et al., 2006). In this study, the results showed that the lower the number of breaths, the higher the swimming speed. Reducing the number of breaths was considered a prerequisite for success in the 50m freestyle races. Therefore, it was suggested that it is preferable for coaches to instruct swimmers to suppress breathing to 0 or 1 time for males and 2 times or less for females.

EARLY SUCCESS IS NOT A PREREQUISITE FOR SUCCESS AT THE ADULT AGE IN SPANISH SPRINTERS

AGUDO-ORTEGA, A., GONZALEZ-RAVE, J.M., SALINERO, J.J.

CASTILLA-LA MANCHA UNIVERSITY

INTRODUCTION: An earlier onset of discipline-specific training and competition during their development years need not necessarily be associated with greater success in senior category (1). In fact, small performance transfer between junior and senior categories has been observed in track and field athletes (2-6). However, most studies have analysed the transition rate only from U18 to senior (2, 4, 7), or from U13 to U20 (6). Studies from U14 to senior category are scarce (3, 5). The main research objective was to quantify the transition rate from success in junior categories (from U14 to U23) to success in senior category, in sprint events in Spain.

METHODS: An observational and longitudinal analysis was carried out using the Royal Spanish Athletics Federation database rankings. We analysed 547 sprinters (238 women and 309 men) from their U14 to their senior stage who ranked in top-20 on at least one occasion during the period 2004 to 2021 in any age category. Contingency tables were used with McNemars statistic to analyse the status in each category, and the transition rate in subsequent categories.

RESULTS: The first entry in top-20 occurs mostly in U14 (42.8%, 234), and the frequency in following categories is progressively lower: 23.6% (129) in U16; 20.2% (111) in U18; 7.5% (41) in U20; 4.4% (24) in U23; and only 1.4% (8) of athletes make their first top-20 entry in the senior category.

The rate of athletes who, being in top-20 positions in any of the different junior categories, achieve the senior top-20 position is 3.8% (9) in the U14; 7.4% (15) in U16; 10.6% (24) in U18; 20.9% (32) in U20; and 31.4% (32) from U23 to senior ($p<0.05$ in all cases).

Transition rates from junior categories with their subsequent categories was statistically significant in all cases ($p<0.05$). From the total of top-20 U14 athletes (234), 31.2% (73) maintained top20 status in U16, 24.4% (57) in U18, 15.4% (36) in U20, and 9% (21) in U23 category. From the total of top-20 athletes in U16 (202), 53.5% (108) remained their top20 in U18, 27.5% (55) in U20 and 16.3% (33) in U23. From the total of top-20 in U18 athletes (228), 45.6% (104) remained their top-20 status in U20 and 26.8% (61) in U23. From the total of top-20 athletes in U20 (153), 43.1% (66) maintained their top-20 status in U23.

CONCLUSION: Data analysis from 547 Spanish sprint athletes showed that: 1) first entry in top-20 position occurs mainly at early ages; 2) the hardest steps to overcome are from U14 to U16, and from U23 to senior; and 3) success in junior categories is not a good predictor of success in the senior category (i.e., low transition rate).

COMPARISON OF HEAT PREPARATION STRATEGIES IN ELITE TRACK AND FIELD ATHLETES PRIOR TO THE DOHA 2019 WORLD ATHLETICS CHAMPIONSHIPS AND TOKYO OLYMPICS 2020NE

ESH, C., GALAN-LOPEZ, N., RACINAIS, S., ADAMI, P., ALONSO, J., CARDINALE, M., GARRANDES, F., BERMON, S., PITSILADIS, Y., TAYLOR, L.

ASPETAR SPORTS MEDICINE HOSPITAL

INTRODUCTION: Increasing data regarding elite endurance athlete preparations for competition in hot conditions continues to emerge, reinforcing our understanding of heat acclimation (HeA), heat acclimatisation (HtA) and/or heat mitigation strategies in this population. However, exertional heat illnesses (EHI) have been reported in non-endurance athletes as well, suggesting this population would also benefit from said preparation strategies. This study explored how track and field athletes prepared for competition in the heat at the Doha World Athletics Championships 2019 (DOHA) and Tokyo Olympics 2020ne (TOKYO).

METHODS: 48 (28 male) DOHA and 36 (15 male) TOKYO athletes completed a paper (DOHA) or online (TOKYO) survey on heat preparation strategies for their stadium events. Athletes were grouped by sex (MALE vs. FEMALE) and climate they lived/trained in [hot (HOT) vs. temperate/cold (TEMPERATE)], with relationships assessed.

RESULTS: 40% (DOHA) and 39% (TOKYO) indicated 'no specific heat training' prior to competition. 58% (DOHA) and 33% (TOKYO) used HtA only, 0% (DOHA) and 17% (TOKYO) used HeA only and 2% (DOHA) and 11% (TOKYO) used both HtA and HeA. 80% of athletes from HOT (46% TEMPERATE) used HeA/HtA prior to DOHA. At TOKYO, MALE athletes predominately selected 'no specific heat training' (53%) or using HtA only (47%), whereas females selected no specific heat training (29%), HeA only (29%), HtA only (24%) and both HeA and HtA (19%). 14% [DOHA (0% TOKYO)] of athletes reported a previous EHI diagnosis while the most common symptoms of EHI reported by athletes during previous training/competition in the heat included cramping (27%), nausea (13%) and severe headache (13%) at DOHA and nausea (22%) and severe headache (19%) at TOKYO. Athletes reported having no pre-cooling (76%) or mid-cooling (73%) strategies for DOHA. At TOKYO pre-cooling strategies included ice slurry/cold water ingestion (53%), direct ice application (47%), cold towel (42%), ice vest (31%), and water/ice pouring/dousing (25%) and ice slurry/cold water ingestion (42%), no strategy (36%), direct ice application (33%) and cold towel (31%) for mid-cooling.

CONCLUSION: The use of HeA/HtA (~60%) by non-road race athletes did not differ between competitions albeit at lower reported adoption than road-race peers at DOHA (63%). Use of HeA/HtA was higher in HOT compared to TEMPERATE (DOHA) and use in FEMALE varied greater (i.e. HeA, HtA or combined HeA/HTA) than MALE prior to TOKYO. Pre- and mid-cooling strategies were more prevalent at TOKYO than DOHA, likely due to differences in stadium environment (air-conditioned DOHA and not at TOKYO). Future research would benefit from: i) a greater understanding of the prevalence/incidence of EHI/EHS among non-endurance athletes'; ii) how knowledge of evidence informed practice and the real/perceived barriers (e.g. access to facilities, impact on usual training) to implementing HeA/HtA impact its use in this population.

EFFECT OF ADDING HEAT STRESS BY LAYERED CLOTHING DURING 3 DAYS OF ENDURANCE TRAINING ON THERMOREGULATORY ABILITY IN A HOT ENVIRONMENT

OKAMOTO, S., GOTO, K.

RITSUMEIKAN UNIVERSITY

INTRODUCTION: INTRODUCTION: Heat acclimation (HA) prevents performance deterioration in a hot environment. Conventionally, HA can be acquired by repetitive exercise sessions in a hot environment. HA improves thermoregulatory ability and exercise performance in a hot environment (1). To acquire HA, daily prolonged exercise (60-90 min) in a hot environment for about 2 weeks is currently recommended (2). In this case, an environmental chamber and a period of 10-14 days are required (3). In the present study, we focused on adding heat stress by layered clothing to create a hot environment. Although layered clothing during 5 days of endurance training improved VO2max (from 52.41 mL/kg/min to 55.24 mL/kg/min; p=0.002), the impact of shorter duration of endurance training with layered clothing remains unclear. Therefore, the purpose of the present study is to clarify the effects of heat stress added by layered clothing during 3 days of endurance training on thermoregulatory during exercise in a hot environment among long-distance runners.

METHODS: METHODS: Nine male long-distance runners conducted three consecutive days of endurance (cycling) training at 50% VO2max for 90 min/day at 15°C with layered clothing (WEAR condition) or short-sleeve shirts and short (CON condition). Each condition was separated six weeks between conditions. During the training sessions, core temperature, heart rate, sweat rate, score of thermal sensation and rate of perceived exertion were evaluated. Before and after training period, heat stress test (HST) consisting of 40 min of endurance (cycling) exercise in a hot environment (35°C, 50%RH) were conducted. During HST, core temperature, plasm volume, heart rate, sweat rate, sweat sodium concentration, score of thermal sensation and rate of perceived exertion were evaluated.

RESULTS: RESULTS: Peak core temperature during training session was 38.39°C in WEAR and 38.31°C in CON, with no significant difference between conditions. The mean heart rate during training session was 126 bpm in WEAR and 120

bpm in CON (P>0.05 between conditions). The average sweat rate during training session was significantly higher in WEAR (2.45%) vs. CON (1.31%) (p<0.001 between conditions). The absolute changes in resting core temperature before and after training period were -0.97% (from 37.22°C to 36.85°C) in WEAR and -0.82% (from 37.19°C to 36.88°C) in CON, with no significant difference between conditions. The relative change in sweat rate after HST were 0.01% (from 1.01% to 1.03%) in WEAR and 8.87% (from 1.03% to 1.12%) in CON, with no significant difference between conditions.

CONCLUSION: CONCLUSION: Three consecutive days of endurance training adding heat stress by wearing layers didn't improve thermoregulatory ability in a hot environment.

MENSTRUAL CYCLE MONITORING IN SPORTS - EVALUATION OF TEMPERATURE PROFILES THROUGHOUT THE CYCLE AND VALIDATION OF TWO DIFFERENT BASAL BODY TEMPERATURE MEASUREMENT METHODS IN FEMALE TRACK AND FIELD ATHL

PILZ, M., SIPPL, J., PLATEN, P.

RUHR UNIVERSITY BOCHUM

INTRODUCTION: In female athletes, training periodization should consider the different phases of the individual menstrual cycle (MC). During the follicular phase (FO) body temperature (BT) remains nearly constant. With the increase of the sex hormone progesterone after ovulation BT increases around 0.25-0.5°C and remains on this level throughout the luteal phase (LU) until progesterone declines again a few days before the next menstruation. The basal (lowest) BT values can be measured during the night. If the variations in BT should be used for the determination of the different phases of MC in sports, however, a practical and cost-efficient method needs to be evaluated. This study aims to compare BT in the external auditory canal right after waking up with the respective temperature of a 24 h intravaginal measurement.

METHODS: The study included competitive female track and field athletes (n=9, 27±6y) with 21 MC in total. During the observation period, the subjects wore a 24 h intravaginal temperature sensor (OvulaRing, VivoSenseMedical GmbH) that recorded BT every 5 min (gold standard). Both, the lowest temperature during the night (low-BT), and the temperature directly after waking up (wake-BT) with OvulaRing were determined from the data. In addition, BT was measured daily in the external auditory tract (ear-BT) with a conventional ear thermometer (SFT 53, Beurer GmbH) directly after waking up. Time of ovulation was determined if there was an increase of BT in the FO of 0.25°C and it lasted for at least three days. Variables were compared using Bland-Altman plots and concordance correlation coefficient analysis.

RESULTS: The mean deviation between wake-BT and ear-BT had a bias of 0.66°C (95%CI [0.34 0.96°C]) with limits of agreement (LoA) ranging from -0.60°C (90%CI [- 1.0 -0.30°C]) to 1.91°C (90%CI [1.61 2.41°C]). The correlation between the two methods was poor (pc=0.05). The mean difference between low-BT (at 2:26am±1:48h) and wake-BT had a bias of 0.60°C (95%CI [0.55 0.65°C]) with LoA ranging from 0.08°C (90%CI [0.02 0.13°C]) to 1.12°C (90%CI [1.06 1.18°C]). The correlation was poor (pc=0.15) between the two time points of BT. Ovulation could be detected with low-BT (ΔFP-LP 0.35°C) and wake-BT (ΔFP-LP 0.28°C), but not with ear-BT, which on average did not allow meaningful ovulation detection (ΔFP-LP 0.09°C).

CONCLUSION: As the correlation between ear-BT and the intravaginal wake-BT at the same time point was weak, the simple and easy-to-use method cannot be recommended for determining the different phases of an individual MC. Further, ovulation detection was impossible using ear-BT measurements. Wake-BT might not be used for information about the lowest BT during the night. Easy-to-use techniques, the optimal time of measurement, and good standardization should be evaluated as alternatives for the exact but cost-intensive intravaginal BT measurement. This project was funded with research funds from the Federal Institute for Sports Science based on a decision by the German Bundestag.

ATHLETE HEAT PREPARATION AT THE WORLD ATHLETICS RACE WALKING TEAM CHAMPIONSHIPS MUSCAT 2022: A SURVEY TO DETERMINE ELITE RACE WALKERS' PRACTICE AND KNOWLEDGE – WORTH A PRACTICAL APPLICATION?

GALAN-LOPEZ, N.1, ESH, C.1,2, LEAL, D.3, GANDINI, S.4, LUCAS, R.5, GARRANDES, F.6,7, BERMON, S.6,7, ADAMI, P.6,7, KAJENIENE, A.8, HOSOKAWA, Y.9, CHRISMAS, B.10, STEVENS, C.11, TAYLOR, L.1,12

INTRODUCTION: Exercise in the heat can compromise athlete endurance performance and health with acclimation/acclimatisation (HA) providing the best protection against these. HA adoption remains far from universal, despite those athletes who used HA prior to the World Athletics Championships in Doha 2019 placing higher whilst showing lower medical events. Continued sport globalisation alongside global warming increase the likelihood of elite sporting events and championships in extreme heat. Therefore, surveying athlete knowledge and exercise in the heat related practice at the World Athletics Race-Walking Teams Championships Muscat 2022 (WRW) would seem prudent to provide further evidence for practice and stakeholder education. The purpose of this study was to assess elite racewalkers' heat preparation strategies and knowledge during the WRW and explore sex and athletes' climate differences.

METHODS: Male (n = 42) and female (n = 24) elite racewalkers completed an online survey prior to WRW. Responses were descriptively analysed by sex (male vs. female) and the climate they live/train in (hot vs. temperate/cold). Relationships within sex and climate were determined with logistic regressions for categorical data. Additionally, relationships between ranking (medallist/top 10 vs. non-medallist/non-top 10) and HA preparation were also assessed.

RESULTS: 43% of athletes did not complete specific HA training. Four surveyed athletes were medallists and had all implemented HA before Muscat (3 heat acclimated only, 1 heat acclimatised only). 15 surveyed athletes ranked within the top 10, being more likely to report preparing for the heat specifically prior to the event, compared to those who did not finish within the top 10 [80% vs. 50%; P = .049, OR = 0.25, 95% CI (0.06% - 1%)]. Climate differences existed for heat acclimatization preparation only [59% hot vs. 21% temperate/cold; P = .002, OR = 8.7, 95% CI (2% - 34%)]. Males [(88%) females (38%)] were more likely to acclimatize for >10 days (P = .020, OR = 0.1, 95% CI (1% - 67%). Females were more likely to not know expected conditions in Muscat [42% vs. 14%; P = .016, OR = 4.3, 95% CI (1% - 14%)] nor what wet bulb globe temperature is [83% vs. 55%; P = .024, OR = 4.1, 95% CI (1% - 14%)]. 83% of athletes were unaware of the World Athletics 'Beat the Heat' leaflet (a previous stakeholder education initiative).

CONCLUSION: Overall, HA use slightly declined prior to the WRW compared to the Doha 2019 Championships. Athletes who implemented HA before the championships tended to place better than those who did not, highlighting the importance and benefit of HA prior to competition. Previous germane educational resources from World Athletics had initial good impact elsewhere but appear to have waned here. Further efforts to provide continually impactful and penetrative educational resources, to bridge the gap between research and practice, particularly in female athletes, are needed in this (and likely many other) sports.

EFFECTS OF HEAT ACCLIMATION IN THOROUGHBRED SKELETAL MUSCLE

EBISUDA, Y., MUKAI, K., TAKAHASHI, Y., YOSHIDA, T., KAWANO, A., MATSUHASHI, T., MIYATA, F., OHMURA, H.

JAPAN RACING ASSOCIATION

INTRODUCTION: Heat acclimation improves exercise performance in hot conditions, and these adaptations involve improvement in skeletal muscle metabolism. However, few reports have described adaptations to hot environments at the cellular level in equine skeletal muscle. The purpose of this study was to determine whether heat acclimation in Thoroughbreds could improve exercise performance and induce skeletal muscle adaptations related to heat stress compared to training in a cool environment.

METHODS: Thirteen trained Thoroughbred horses (4.6 ± 0.4 [mean ± SE] years old; 498 ± 19 kg) were assigned to train 3 days/week for 3 weeks either in a cool condition (COOL; Wet Bulb Globe Temperature [WBGT] 12-13°C; n = 6) or a hot condition (HOT; WBGT 29-30°C; n = 7). The training protocols consisted of cantering at 7 m/s for 2 min and at the speed eliciting 90% of maximal oxygen consumption (VO2max) for 2 min 2 days/week, and cantering at 7 m/s for 3 min 1 day/week, followed by a 20-min walk in each session. Before and after the training period, standardized exercise tests consisting of cantering for 80 s in HOT at the speed sustaining 112%VO2max until fatigue were conducted. Biopsy samples were obtained from the middle gluteal muscle before exercise tests for western blotting and real-time RT-PCR. Data were analyzed with using paired t-tests ($P < 0.05$).

RESULTS: Time to exhaustion increased by 24% in HOT (79 ± 9 s to 98 ± 8 s, P = 0.02) after 3 weeks of heat acclimation, but did not change significantly in COOL (82 ± 7 s to 76 ± 5 s, P = 0.40). Heat shock protein (HSP)-70 protein increased significantly only in HOT (COOL, 1.02-fold, P = 0.82; HOT, 1.37-fold, P < 0.01), whereas HSP-70 mRNA was similar in both groups (COOL, 1.11-fold, P = 0.55; HOT, 1.07-fold, P = 0.64). In contrast, HSP-90 mRNA increased significantly only in HOT (COOL, 1.04-fold, P = 0.84; HOT, 1.50-fold, P = 0.01), and HSP-90 protein tended to increase in HOT (COOL, 1.07-fold, P = 0.48; HOT, 1.17-fold, P = 0.06). Gene expression of succinate dehydrogenase complex flavoprotein subunit A (SDHA; COOL, 1.15-fold, P = 0.33; HOT, 1.27-fold, P = 0.04), hypoxia inducible factor (HIF)-1α (COOL, 1.05-fold, P = 0.81; HOT, 1.67-fold, P < 0.01), and pyruvate dehydrogenase kinase isozyme 4 (PDK4; COOL, 1.89-fold, P = 0.29; HOT, 3.25-fold, P = 0.02) increased significantly only in HOT. Peroxisome proliferator-activated receptor γ coactivator (PGC)-1α did not change significantly in protein (COOL, 1.28-fold, P = 0.31; HOT, 1.11-fold, P = 0.65) or mRNA (COOL, 1.36-fold, P = 0.33; HOT, 1.46-fold, P = 0.10) expression.

CONCLUSION: Our results demonstrate that heat acclimation improves exercise performance and increases expression of various proteins and mRNAs, including HSPs, SDHA, HIF-1α, and PDK4. These results suggest that heat acclimation activates protective responses to heat stress and increases signaling pathways to induce mitochondrial adaptations in skeletal muscle.

DEVELOPMENT OF A NON-INVASIVE THERMOMETRY USING AN INFRARED THERMAL-IMAGING CAMERA WITH RATS RUNNING AT VARIOUS SPEEDS: A PILOT STUDY

KANG, Y., HIRAGA, T., HATA, T., KUNII, T., TORMA, F., OKAMOTO, M., SOYA, H.

UNIVERSITY OF TSUKUBA

INTRODUCTION: Exercise-induced increase in body temperature is a crucial factor for determining exercise performance (Gonzalez et al. 1995). Typically, body temperature during exercise is measured using rectal and abdominal temperatures, which are known to reflect increased temperatures dependent upon exercise duration and intensity (Samuel et al., 2015). However, such temperature measurement methods can seem invasive and appear to be stressful for animals, which may interfere with a precise molecular and neurocircuitry analysis behind body temperature regulation with exer-

cise. This precludes us from measuring exercise-related body temperature using conventional methods and makes us to use a non-invasive thermal camera. We have been developing a treadmill running model for rats that compels different running speeds based on the lactate threshold, focusing on hormonal and metabolic changes (Soya et al., 2007). We thus aimed to establish an animal model for evaluating body temperature change dependent upon running speeds that will extend our current running model by allowing the measurement of the body surface temperature using a non-invasive thermal camera.

METHODS: F344 male rats (10-12 weeks old) were used in this study. Based on LT assessment (LT speed: 21.0±0.90 m/min), 3 groups (S: sedentary group resting on the treadmill, n = 7; L: light exercise group running at 10 m/min, n = 7; and V: vigorous exercise group running at 25 m/min, n = 8) were created, and the rats ran or rested on a treadmill for 30 minutes. Body surface temperature (BST) was measured using an infrared thermal-imaging camera (InfRec R550, Nippon Avionics, Japan) before and after running, and blood lactate and glucose levels were measured at the same time.

RESULTS: Thirty minutes of treadmill running was revealed to increase the BST depending on the running speed, whereas resting did not produce changes in temperature. Note that there was no difference in room temperature among groups. Blood lactate levels increased solely in the V group.

CONCLUSION: The findings described above are consistent with those of the previous study (Soya et al., 2007), which demonstrated the validity of an exercise model based on LT, even with the use of a thermal camera. We found that the rat BST increased during treadmill running in a manner dependent upon speed, which is consistent with previous studies using conventional means to measure core body temperature. This implies that we have successfully developed a running model that can non-invasively measure changes in exercise-related body temperature. Establishing such a model may help to explore brain molecular and neurocircuitry mechanisms for thermoregulation during exercise.

INFLUENCE OF (IN)CONGRUENT VISUAL INFORMATION ON THERMAL PERCEPTION DURING EXERCISE IN THE HEAT: A RANDOMISED CONTROLLED CROSSOVER TRIAL

MAYES, H.1, NAVARRO, M.1, SATCHELL, L.2, MUELLER, D.3, BADARIOTTI, J.1, WHITE, D.1, TIPTON, M.1, ANDO, S.4, COSTELLO, J.1

1. UNIVERSITY OF PORTSMOUTH, UK. 2. UNIVERSITY OF WINCHESTER, UK. 3. VRIJE UNIVERSITEIT AMSTERDAM, NETHERLANDS. 4. THE UNIVERSITY OF ELECTRO-COMMUNICATIONS, JAPAN.

INTRODUCTION: Human thermoregulation is vital to human survival, and is regulated by behavioural and autonomic responses. Behavioural responses are the more powerful of the two mechanisms, and are driven by subjective perceptual awareness of the thermal environment. Perception itself is a holistic experience of all senses, however there is evidence to suggest visual information, is prioritised over other sensory information. We have recently demonstrated that this relationship is not well understood, particularly when humans are exposed to extreme environments, or during exercise. This study tested the hypothesis that a 'cold' visual virtual environment would change thermal perception when compared to a 'hot' visual virtual environment during exercise in a warm environment.

METHODS: Sixteen healthy, active participants (six females) who were not susceptible to motion sickness volunteered for the study [mean (SD), age: 23.4 (3.7) years;(" V") ̇O2max: 38.2 (5.8) mL·kg-1·min-1]. In a within participant, randomised, crossover design, volunteers completed three experimental sessions, involving a 30-minute bout of cycling in 35 °C (50 % r.h.), whilst exposed to three different visual environments [no virtual reality (NoVR), virtual reality displaying an arid landscape (HotVR), and virtual reality displaying a snow covered landscape (ColdVR)].

Thermal sensation, thermal comfort, rating of perceived exertion, heart rate, core temperature, four-site skin temperature were recorded. Mean skin temperature, mean body temperature, perceptual strain index, and physiological strain index were subsequently calculated. Plasma cortisol was also analysed before and after each trial. Data were analysed using a 3 (Condition: NoVR, VRHot, VRCold) x 4 (Time: Pre, 10-, 20-, 30- min post onset of exercise) repeated measures ANOVA. Cortisol was analysed with a 3 (Condition: NoVR, VRHot, VRCold) x 2 (Time: pre, post) repeated measures ANOVA. The main effects of condition, time, and their interaction were explored, with statistical significance accepted at $p < 0.05$.

RESULTS: Cycling in the heat resulted in a significant increase in all variables over time in all conditions (all $p < 0.05$). Manipulation of the visual environment did not alter perceptual, physiological, or biochemical variables (all $p > 0.05$). Similarly, no significant interactions were observed.

CONCLUSION: It is concluded that using VR to manipulate the virtual environment during cycling in the heat does not meaningfully alter perceptual, physiological, or biomarkers of hypothalamic-pituitary-adrenal axis activity.

PSYCHOLOGICAL AND PHYSIOLOGICAL CHANGES TO THE COLD PRESSOR TEST IN ADOLESCENT HANDBALL PLAYERS WITH NORMAL MENSTRUATION

SZIRÁKI, ZS., ALSZÁSZI, G., ALMÁSI, G., ANNÁR, D., ZSÁKAI, A., NYAKAS, CS., SZMODIS, M.

HUNGARIAN UNIVERSITY OF SPORT SCIENCE

INTRODUCTION: The menstrual cycle involves significant changes in hormone levels, which cause physical and psychological changes in women, which are further affected by stress. The cold-pressor test (CPT) in which subjects immerse their forearms in ice water is among the most commonly used laboratory stressors.

METHODS: Twenty-seven adolescent female elite athletes (mean age 16.6 ± 1.69 years) from a rural Hungarian womens handball club were included in the study. Anthropometric measurements (anthropometer, BIA, Tanner-scale) were taken

2 days before the socially involved cold pressor test. According to the menstrual cycle, 2 groups (follicular, and luteal) were formed. The average day of the menstrual circle in the follicular phase (n=12) was 8.38 ± 3.33 and in the luteal (n=15) 21.3 ± 5.52 days. Before the simulation, immediately after, and 30 minutes later, a saliva cortisol sample, blood pressure, and heart rate were measured. During the 30-minute break, the participants completed a psychological test package (SWLS, PSS, CD-RISC, HA-7, ACSI-28, SAS-2, MHC-SF).

RESULTS: Among the physiological parameters, the diastolic blood pressure value after the simulation was measurably higher (p= 0.003), as well as the heart rate (p= 0.046). No significant difference (p>0.05) could be detected in the salivary cortisol values and in the other cardiovascular parameters. The score on the Perceived Stress Scale was significantly higher (p= .015) in the follicular group (29.8 ± 7.17 points) than in the luteal group (22.5 ± 7.29 points). Furthermore, ACSI-28 confidence was significantly higher (p= 0.045) in the luteal group (13.2 ± 1.76 points) than in the follicular group (11.9 ± 1.38 points). The tolerance time spent voluntarily in the simulation did not differ (p>0.05) between the two groups.

CONCLUSION: The data showed that neither the resting nor the salivary cortisol parameters following the stress simulation were different in the two stages of the menstrual cycle. Regardless, psychological differences were found. These results contribute to the wide range of stress simulation studies, supplementing them with adolescent subjects.

HIGH-GROOVE MUSIC BOOSTS SELF-SELECTED JOGGING SPEED AND POSITIVE MOOD IN UNIVERSITY STUDENTS

HIROTA, Y.1, SUWABE, K.1,2, OTSUKI, T.1, KAWASE, S.3

1RYUTSUKEIZAI UNIVERSITY , 2UNIVERSITY OF TSUKUBA , 3KOBE GAKUIN UNIVERSITY

INTRODUCTION: Around 27.5% of adults worldwide do not meet the recommended requirement of 150 minutes a week of moderate-to-vigorous physical activity. Positive affective response to exercise promotes exercise adherence; however, pleasure mood is reduced along with an increase in the exercise intensity [1]. To address this dilemma, listening to music during exercise may helpful. Since music has positive impacts on endurance performance and perceived enjoyment in vigorous-to-maximal intensity [e.g. 2], it may enhance both exercise intensity and pleasure in health promotion situations (light-to-moderate intensity exercise). We tested this hypothesis using groove music, which induces a sensation of "wanting to move to the music" accompanied by positive affective responses [3].

METHODS: Fourteen Japanese university students (8 male) participated in the two experimental conditions, High-Groove (HG) and Low-Groove (LG), with a within-subject, crossover design. Participants performed two sessions of three minutes running exercise on a treadmill at least 15 minutes apart in randomized order. Before the experiment, they previewed tempo-matched 12 pairs of high/low-groove music lists and selected one of them to listen to during their exercise session. The participants were asked to run at a comfortable pace and were allowed to adjust the treadmill speed during the first minute. During exercise, heart rate (HR) and treadmill speed was recorded. After each exercise session, Borg's rating of perceived exertion (RPE), psychological mood (Two-Dimensional Mood State), and rating of groove [4] were measured. We compared each parameter using a paired t-test (two-tailed, $\alpha = 0.05$). Values are mean±SE.

RESULTS: Rating of groove was higher in HG (HG: 32.1±1.2; LG: 16.0±1.5). Self-paced speed of treadmill was faster in HG (HG: 5.9±0.2; LG:4.6±0.3 [km/h]). HR (HG: 134.2±5.5; LG: 115.5±4.8 [bpm]) and RPE (HG: 12.2±0.6; LG: 9.9±0.7) were higher in HG. Exercise intensity was within the range of moderate in HG whereas it was light in LG. Psychological arousal levels (HG: 1.4±0.5; LG: -0.9±0.5) and pleasure levels (HG: 3.1±0.8; LG: 0.7±0.6) post exercise were higher in HG.

CONCLUSION: Listening to high-groove music listening during running increased not only the self-selected speed, which increased the exercise intensity measured by HR and RPE, but also enhanced the positive affective response (arousal and pleasure) to lower intensity exercise. These findings are interesting because groove music was beneficial in elicit a positive mood beyond the potential negative impact of increasing the exercise intensity. Although the long-term effects are unclear from this short-time, acute intervention study, the results suggest that listening to high-groove music during exercise may be helpful to increase both exercise intensity and adherence in health promotion situation.

RELATIONSHIP OF PHYSICAL ACTIVITY LEVEL, SEDENTARY BEHAVIOR AND PHASE ANGLE IN YOUNG ADULTS.

GARCÍA-LAGUNA G., TORDECILLA-SANDERS A., SEMILLERO, W.

UNIVERSIDAD DEL ROSARIO

INTRODUCTION: The phase angle (PAn) has been considered an indicator of the state of cell health, cell mass, and the integrity of the cell wall. Different authors have found a relationship between the levels of Physical Activity (PA) and PAn, however, this relationship has been little explored with sedentary behavior (SB) in young adults.

METHODS: Observational, analytical cross-sectional study. Young adults of legal age, physiotherapy students at the Universidad del Rosario (UR) in Bogotá-Colombia, without cardiometabolic disease or presenting an injury that prevented

them from performing PA were randomly selected. The approval of the ethics committee of the UR was obtained. After signing the informed consent, PA was evaluated with the IPAQ, SB with the SITQ-7D, and PAn through octagonal bioimpedance. Differences between sex and the relationship between PAn with AF and SB were determined, and statistical significance was assumed with a value of $p<0.05$.

RESULTS: 228 young people aged 20.8±2.9 years participated, who mainly have a moderate (50.4%) and high (43.4%) PA level, spending 11.9±0.66 and 10.2±4, 2 hours of SB during the week and weekend, respectively, and 5.5±0.66 degrees of PAn. A relationship was found between PAn and PA METs ($r=0.322$, $p<0.001$), but not with SB ($p>0.05$).

CONCLUSION: Significant differences were found in PAn and SB on the weekend between men and women, in addition to the direct relationship between PAn and SB in young adults, which is in line with what was reported by Mundstock E, et al. which shows the relevant role of PA in relation to health. More studies are required to analyze SB and its effects on population health, according to Ribeiro AS, et al. and Souza MF, et al., the phase angle is related to muscular resistance training and therefore with strength in older adults, so the relationship between SB, PA and some components of the condition should be explored. physical as muscular strength in the young adult population.

CHANGES IN PHYSICAL ACTIVITY AMONG 17-YEAR-OLD ICELANDIC ADOLESCENTS – OBJECTIVE AND SUBJECTIVE DATA FROM TWO COHORTS

STEFANSDOTTIR, R., HJALMARSSON, B., ROGNVALDSDOTTIR, V., JOHANNSSON, E.

UNIVERSITY OF ICELAND

INTRODUCTION: During late adolescence changes in health occur and previous data has shown that physical activity declines as teenagers head into young adulthood (1). However, maintaining healthy lifestyle from adolescence to adulthood has been linked to numerous lifestyle benefits (2), thus teenagers aged 14–17 years are recommended to accumulate at least 60 minutes of moderate-to-vigorous intensity, mostly aerobic, physical activity, across the week (3). The aim of the currents study was to examine how physical activity, measured both objectively and subjectively had changed in two cohorts of 17-year-old Icelandic adolescents from 2017 to 2021.

METHODS: In spring 2017 we measured free-living physical activity with wrist actigraphy for one week in 160 adolescents (96 girls, born 1999) and asked participants to answer an online questionnaire to measure subjective physical activity. In spring 2021, 171 adolescents (107 girls) in a cohort born 2003 answered the questionnaire and a subset of 74 (45 girls) agreed to wear wrist actigraphy for one week.

RESULTS: Objectively measures of average weekly physical activity decreased 4.1% and dropped from 1786 counts/min of wear/day in 2017 to 1713 counts/min of wear/day in 2021. However, the difference was not statistically significant ($P=0.18$). When subjective activity was explored, with hours of weekly physical activity, in 2017 40% of adolescents did 6 hours or more of physical activity per week. However, in 2021 only 30% of 17-year-olds did 6 hours or more of weekly physical activity. As a result, 60% of the adolescents were exercising less than the recommended one hour a day in 2017, and that number had increased to 70% in 2021.

CONCLUSION: In a span of 4 years, Icelandic older adolescents reduced their general physical activity both measured objectively and subjectively. Further there was an increase in the number of adolescents that did not meet the recommendation of at least 60 mins (1 hour) or more of moderate-to-vigorous intensity physical activity daily. This data indicates that in only 4 years, or between 2017 to 2021, older Icelandic adolescents were moving less, for shorter amounts of time and even fewer are reaching the recommended physical activity guidelines per week.

THE EFFECT OF EXERCISE HABITS ON BODY COMPOSITION OF FEMALE UNIVERSITY STUDENTS

OHTA, M.1, YOSHIKO, A.1, KURAMOCHI, R.1, MITSUYAMA, H.1, MITA, Y.2, TANAKA, N.3

1:CHUKYO UNIVERSITY, 2: SUGIYAMA JOGAKUEN UNIVERSITY, 3:NAGOYA UNIVERSITY

INTRODUCTION: Skeletal muscle mass (SMM) increases with development and reaches its peak around age 20. Thereafter, it is known to decrease SMM with age. Furthermore, SMM decreases with inactivity. On the other hand, body fat percentage (%Fat) increase relative to a decrease in SMM and is also increased by inactivity. Changes in body composition due to increases in body fat and decreases in SMM pose a risk for future disease. Recently, it has been reported that the number of young Japanese women with the exercise habit has been decreasing. Considering that women potentially have less SMM than men, the lack of exercise habit may have more impact on their future health. The purpose of this study was to examine the effects of past and present exercise habits on body composition among female university students.

METHODS: The subjects were 61 female university students aged 18-22 years (age: 20.2 +/- 1.0 years, height: 157.5 +/- 5.6 cm, weight: 51.8 +/- 6.6 kg). Exercise habits were defined as exercising for at least 1 hour per session, twice a week for at

least two years. The subjects were divided into three groups: the group with current exercise habits (CEH group, n = 21), the group with past exercise habits until one year ago (PEH group, n = 21), and the group with no exercise habits from the past to the present (NEH group, n = 19). The whole body and segmental SMM and %Fat values were measured by a body composition analyzer, and then SMM per body weight (%SMM) was calculated. A one-way ANOVA was performed to examine significant difference among the three groups.

RESULTS: The duration of exercise was significantly longer in the CEH group (6.9 +/- 3.4 years) than in the PEH group (5.2 +/- 1.8 years). The CHE group had larger total SMM, segmental SMM, total %SMM, and segmental %SMM than the NEH group. The CEH group also had a significantly lower %Fat than the NEH group. The CEH group had a significantly higher %SMM of the upper limb than the PEH group. In the PEH group, the %SMM of the lower limb was significantly larger than in the NEH group.

CONCLUSION: We found that the CEH group had larger SMM and a lower body fat percentage than the NEH group. The results suggest that continuing exercise habits at a young age may reduce in future health risks. Although the PEH group had a lower %SMM of the upper limb than the CEH group and a higher %SMM of the lower limb than the NEH group, there was no clear indication of the effect of past exercise habits or the loss of exercise habits. In the future, it will be necessary to increase the number of subjects and examine with a stricter classification of the type, frequency, and duration of exercise.

RATES OF COMPLIANCE AND ADHERENCE TO HIGH-INTENSITY INTERVAL TRAINING: A SYSTEMATIC REVIEW AND META-ANALYSES

SANTOS, A., BRAATEN, K., MACPHERSON, M., VASCONCELLOS, D., VIS-DUNBAR, M., LONSDALE, C., LUBANS, D., JUNG, M.E.

UNIVERSITY OF BRITISH COLUMBIA - OKANAGAN

Introduction

The purposes of our systematic review and meta-analyses were to determine: 1) rates of compliance and adherence to supervised and unsupervised high-intensity interval training (HIIT) interventions for insufficiently active adults and adults presenting with a medical condition, and 2) whether compliance and adherence rates were different between HIIT and moderate-intensity continuous training (MICT) interventions.

Methods

Articles that reported on adults who were 1) insufficiently active or presenting with a medical condition, and 2) involved in a HIIT intervention which measured compliance or adherence were included. A search was employed in six databases. Screening of articles and data extraction were completed by two independent reviewers and consensus was reached through deliberation. Risk of bias was assessed using the RoB 2.0 or ROBINS-I. HIIT and MICT compliance and adherence rates were calculated via weighted averages. Meta-analyses were conducted to discern differences in compliance and adherence rates between supervised and unsupervised HIIT vs. MICT interventions. Sensitivity analyses, publication bias, and sub-group analyses were also conducted. Overall quality of the cumulative evidence was appraised using GRADE.

Results

188 studies were included (n=8928). Most studies were English, single-center, prospective randomized controlled trials. 29.3% of studies were identified as having high risk of bias, and 20.2% moderate risk. Compliance to supervised HIIT interventions averaged 89.4% (SD:11.8%), while adherence to unsupervised HIIT averaged 63% (SD:21.1%). Compliance and adherence to MICT averaged 92.5% (SD:10.6%) and 68.2% (SD:16.2%), respectively. Based on 65 studies, meta-analysis revealed that compliance rates were not different between supervised HIIT and MICT interventions [Hedge's g=0.026 (95%CI: -0.090–0.143), p=.66]. Results were robust and low risk of publication bias was detected. Sub-group analysis indicated compliance favoring HIIT for insufficiently active but otherwise healthy adults [Hedge's g=0.262 (95%CI: 0.048–0.476), p=.017]. Quality of the evidence was rated as moderate. Based on 10 studies, adherence rates were not statistically different between unsupervised HIIT and MICT interventions [Hedge's g=-0.313 (95%CI: -0.681–0.056), p=.096]. Sub-group analysis may point to differences in adherence rates dependent on the method of measurement used. Quality of the evidence was rated as very low.

Discussion

Compliance to supervised HIIT interventions is high and comparable to that of supervised MICT among insufficiently active adults and adults with a medical condition. Adherence to unsupervised HIIT interventions is moderate and comparable to MICT, although results should be interpreted with caution due to high heterogeneity and very low quality of evidence. Further research is needed, taking into consideration the exercise protocols employed, methods of outcome measurement, and timepoints of measurement.

A 4-YEAR FOLLOW UP STUDY FROM THE 40-WEEKS FOOTBALL AND ZUMBA WORKPLACE INTERVENTION STUDY AMONG FEMALE HOSPITAL EMPLOYEES IN NORWAY.

BARENE, S., KRUSTRUP, P., LITLESKARE, S., HOLTERMANN, A.

INLAND NORWAY UNIVERSITY OF APPLIED SCIENCES

INTRODUCTION: This 4-year follow-up study of a 40-week cluster-randomised workplace intervention, evaluates the long-term effects of Football and Zumba on aerobic capacity (VO2max), body composition, blood cholesterol, as well as self-reported muscle pain among female hospital employees.

METHODS: Initially, 107 female hospital employees were divided into the two exercise groups Football and Zumba, which were offered 1-2 exercise sessions over 40 weeks, and a control group. Measurements were carried out at baseline, 12 and 40 weeks. The current study was conducted 4 years after the end of the intervention, and included a total of 43 participants, divided into the Football group (n=14), the Zumba group (n=17) and the Control group (n=12). For reasons of statistical power, the intervention groups were combined in the statistical analyses.

RESULTS: Of the total of 31 participants in the intervention groups, 7 in the football group and 3 in the Zumba group maintained regular exercise in their respective activities 4 years after the end of the intervention. Otherwise, there were no significant differences between self-reported amount of exercise between the three groups in the period from the end of the intervention to the 4-year follow-up. Based on a linear model analyses, the intervention groups revealed a significant higher overall mean in VO2max (1.0 ml/kg/min, 95% CI 0.31 to 1.71, p = 0.005) and lower limb bone mineral density (BMD) (0.02 g/cm2, 0.00 to 0.04, p = 0.024) four years after the end of the intervention compared to the controls. Moreover, the intervention groups revealed a significant lower duration of pain during the past 3 months in the neck-shoulder region (-6.8 days, 95% CI, -10.9 to -2.6, p = 0.002), S-Cholesterol (-0.17 mmol/L, 95% CI -0.31 to -0.02, p = 0.023), LDL Cholesterol (-0.13 mmol/L, 95% CI -0.26 to -0.00, p = 0.049), as well as total body fat mass (-671 g, 95% CI, -1164 to -178, p = 0.008) compared to the controls.

CONCLUSION: This 4-year follow-up study among female hospital employees indicates that several of the beneficial health effects achieved through 40 weeks of football and Zumba organized by the workplace, are maintained after 4 years despite a relatively low degree of compliance.

THE COVID-19 PANDEMIC DECREASES CARDIORESPIRATORY FITNESS. A 3-YEAR FOLLOW-UP STUDY IN INDUSTRY

SKARE, Ø.1, MAMEN, A.2, SKOGSTAD, M.1

1 NATIONAL INSTITUTE OF OCCUPATIONAL HEALTH 2 KRISTIANIA UNIVERSITY COLLEGE

INTRODUCTION: The COVID-19 pandemic was first noticed in China in December 2019 1. Already in mid-March 2020, the Norwegian society closed, with a gradual opening during spring 2020 through mid-July 2020. During autumn 2020 and winter/spring 2021, parts of Norway closed again; enterprises and, in particular, restaurants closed, and the public was again encouraged to work at home. During the spring and summer of 2021, the number of infected decreased in line with an increase in vaccination and ultimo September, Norway was back to normal. However, primo December 2021, the Omicron-mutation was detected in Norway, and new limitations of movements were enforced until February the12th, 2022. Throughout the pandemic, there were temporary regional differences in closure in Norway.

METHODS: The present study is a prospective follow-up study of early manifestation of cardiovascular disease in industry workers in which both shift workers and day workers (controls) participate. In the spring and summer of 2018, we invited 172 workers, at two insulation material plants in Eastern Norway, whereof 94 workers agreed to participate. We examined these workers in August 2018, and August 2021 and in a subset study in October 2018. We here report results obtained among all workers who attended at baseline (BL) and three years afterwards at follow-up (FU). According to the protocol, we excluded persons with serious medical conditions, leaving 86 eligible participants, of whom we examined 70 at FU. After five minutes of rest, while sitting, we measured resting heart rate (RHR). We used the mean of three measurements. Maximal oxygen uptake (VO2max) was assessed by a standardized graded ergometer cycle test and direct measurement of oxygen uptake with a Cosmed K5 metabolic analyser. Data were analysed with Stata 17, and p-values below 0.05 were considered significant. The Regional Ethics Committee in Oslo approved the study (2018/1258). We informed the participants about the study, and they gave their written consent to participate (ISRCTN42416837).

RESULTS: RHR increased from 61.3 to 64.4 beats per minute (95%CI, 0.8, 5.4). Self-reported PA decreased by 43.9 min/week, (95%CI, -73.5, -14.4), and VO2max decreased from 39.6 ml/kg/min at BL to 34.0 at FU, a reduction of 5.6 ml/kg/min (95%CI, -7.6, -3.7). Adjusted for actual age, the corresponding figure for VO2max was 5.4 ml/kg/min, (95%CI, -7.4, -3.4), an annual loss of 4.6%.

CONCLUSION: The PA decrease did not affect BMI and fat mass in this study over 3 years. This concomitant stability in BMI and fat mass does not, however, rule out a negative effect on fat metabolism, since decreasing energy expenditure is associated with an increase in intra-abdominal fat without necessarily increase of BMI at the same time. In line with the decrease in self-reported vigorous PA and an increase in RHR, we found a significant decrease in VO2max during a 3-year follow-up of industry workers, possibly a result of physical inactivity during the COVID-19 pandemic.

PHYSICAL CONDITION AND KLOTHO LEVELS IN ADULTS WITH CYSTIC FIBROSIS

YVERT, T., SOSA-PEDRESCHI, A., SANZ-SANTIAGO, V., RENGHEA, A., GIRÓN-MORENO, R., LOPEZ-NEYRA, A., BURGOS-POSTIGO, S., BARCELÓ-GUIDO, O., PÉREZ-RUIZ, M., ITURRIAGA, T., SANTIAGO-DORREGO, C.

UNIVERSIDAD POLITÉCNICA DE MADRID

INTRODUCTION: It is now well established that physical condition level is one of the main predictors of the disease's prognosis in people with cystic fibrosis (CF). Besides, the α-Klotho protein (αKl) is an emerging biomarker of health and aging, which further seems to be related to the levels of physical fitness in healthy population. In CF patients, recent publications suggest αKl could act: (i) at cellular level, helping to improve mucus clearance from the lung epithelium trough potassium channels activation; and (ii) to regulate some inflammatory cytokines and therefore contribute to control the persistent inflammation characteristic of CF patients.

Our aim in this study was thus to determine the possible relations between αKl levels and physical condition in CF adult patients and healthy controls.

METHODS: 89 subjects were analyzed: 36 CF patients (18 women) and 53 controls (18 women) of the same age. The analyzed variables were: age, weight, height, BMI, maximum oxygen consumption (VO2max), blood levels of αKl and interleukin 10 (IL10).

RESULTS: Age and BMI were: 33.0±9.3 years and 20.7±2.1 kg/m2 in CF women; 33.1±9.4 years and 21.5±2.6 kg/m2 in healthy women; 31.78±7.6 years and 22.8±2.3 kg/m2 in CF men and 30.6±7.4 years and 23.3±2.1 kg/m2 in healthy men.

Significant differences were found comparing CF subject vs. controls for VO2max ($p<0.001$) in total sample, as well as dividing by sex: VO2max was 30.5±8.2 ml/kg/min in CF subjects (26.4±5.6 ml/kg/min women, 34.7±8.3 ml/kg/min men) and 51.6±7.1 ml/kg/min in healthy subjects (44.7±4.3 ml/kg/min women, 55.2±5.4 ml/kg/min men).

There were no significant differences comparing both groups for αKl levels: 968.8±713.2 pg/ml in CF subjects and 917.1±305.5 pg/ml in healthy subjects. Nevertheless, interesting opposite significant differences were observed separating by sex: CF women presented higher levels than controls (1283.4±891.6 pg/ml vs. 772.7±376.8 pg/ml, $p=0.032$, Cohen's $d=0.746$), while CF men presented lower levels than controls (654.2±206.9 pg/ml vs. 991.4±234.6 pg/ml, $p<0.001$, Cohen's $d=1.494$).

Correlations analysis showed significant relations between VO2max and αKl, in opposite direction between the two groups: healthy subjects with higher levels of αKl presented higher VO2max ($r=0.319$, $p=0.02$), while CF subjects with higher levels of αKl presented lower VO2max ($r=-0.451$, $p=0.006$). No significant relations were observed between IL10 and αKl or VO2max.

CONCLUSION: Opposing results found for αKl levels between men and women could be explain by possible relations between αKl and sex hormones previously described in literature.

αKl levels and VO2max are inversely correlated between patients with CF and healthy subjects. We hypothesize the higher αKl levels in CF patients with worse physical condition may be due to higher chronic inflammatory state that activates processes regulated by anti-inflammatory proteins, αKl being one of them.

CHANGES IN INSULIN RESISTANCE AND BODY COMPOSITION FOLLOWING 14 DAYS OF BED REST WITH OR WITHOUT AN EXERCISE COUNTERMEASURE.

HAJJ-BOUTROS, G.

MCGILL UNIVERSITY HEALTH CENTER

INTRODUCTION: Mechanical unloading during spaceflight (microgravity) and prolonged bed rest leads to loss of muscle mass and strength, as well as to the development of insulin resistance. Prolonged 6-degree head-down tilt bedrest (HDTBR) is an analogue to microgravity. In the present study we investigate whether or not exercise can mitigate changes in body composition and insulin sensitivity induced by 14-days of HDTBR.

METHODS: Twenty-two participants (59±3y; 24.9±3kg/m2) underwent 14 days of HDTBR with (n=11) or without (n=11) exercise as a countermeasure. Body composition was measured using iDXA and MRI before and after HDTBR. Oral glucose tolerance test (OGTT) was performed at baseline and during HDTBR (day 3, 9, 13) and recovery.

RESULTS: Both the exercise and control group experienced significant weight loss (-1.2[-1.9, -0.5]) vs. (-1.1[-1.6, -0.6]), which was driven by a significant muscle mass loss in the control group (-0.5[-1.1, 0.01]) vs. (-0.8[-1.3, -0.3]) and significant fat mass loss in the exercise group (-0.7[-0.9, -0.4]) vs. (-0.3[-0.5, -0.1]). Compared with baseline, the OGTT performed during HDTBR remained similar and showed significantly lower glucose excursion curves in the exercise compared to the control group ($p<0.05$). However, following a 6-day recovery period, the glucose response to OGTT returned to similar values as seen at baseline in the control group.

CONCLUSION: Loss of muscle mass and impaired glucose homeostasis can be mitigated with regular exercise during 14 days of HDTBR in healthy individuals. Additionally, the exercise protocol in this study may represent the basis of developing effective inflight exercise countermeasures helping astronauts to maintain their musculoskeletal health while in space. It may likewise assist patients requiring bed rest during hospitalization. These findings highlight the need to elucidate the mechanisms through which exercise exerts such benefits.

PITFALLS OF DATA MONITORING BY USE OF DIGITAL DEVICES OF AN ACTIVITY PACING STUDY PROTOCOL IN PEOPLE WITH HIV

MARMONDI, F., ALBERGONI, A., PENNACCHI, M., CERIZZA, C., TURRINI, F., CASTAGNA, A., GALLI, L., SARTOR, F., CINQUE, P., BONATO, M.

IRCCS SAN RAFFAELE SCIENTIFIC INSTITUTE

INTRODUCTION: Physical activity has been shown to improve cardiorespiratory fitness (CRF) in people living with HIV (PLWH). However, exercise adherence in this population is low. Smart technology has been suggested to improve adherence by providing motivational feedbacks and measuring activity and fitness parameters. The aim of this study was to investigate health and quality of life benefits to monitor activity pacing (AP), a strategy to manage fatigue during exercise, in PLWH by using an actigraph and a smartphone app showing exercise details directly to participants.

METHODS: This was a randomized-controlled study divided in two phases: 2-week Observational Phase (OP), in which subjects performed their daily routine and were monitored in a subject-blind configuration of devices; 16-week Training Phase (TP), with subjects either randomized into an Experimental Group (EG: no-blind configuration) or Control Group (CG: blind configuration). The actigraph (Philips Health Band) provided tracking from all participants of HR, daily steps, minutes per day with steps >100/min (moderate activity) or >130/min (vigorous activity), via Bluetooth to a mobile app installed on subjects' smartphone, which transmitted data to Philips Actigraphy Server System (PASS) website where were accessible to trainers. At baseline (BL) and end of study (W18) participants were tested for body composition (BMI, hip, waist circumference), CRF (6MWT), blood lipids (total-, HDL-, LDL-C).

RESULTS: Twenty-four participants were enrolled and randomized 12 in EG and 12 in CG. Five dropped-out during the follow-up. During the study we had several technical issues regarding band/app pairing and/or data transmission to the website, depending on different models, operating systems, and configurations of mobile phones. Therefore, we were not allowed to carry out the study following the experimental design (i.e., comparison of data between EG and CG), and could only analyze data from the whole group who completed W18 assessment (N=19). Considering a total of 2581 days of monitoring, we collected total complete data of 963 days (40%); this fraction was significantly higher during the OP than in the TP [219/266, (83%) vs. 744/2128, (35%); p<0.0001, Chi-Square Test]. There were no significant differences in distance [median: 504 (IQR: 453-588) m vs 522 (477-597) m, P=0.860)] and VO2 at steady state [15.5 (12.5-21.6) ml/kg/min vs 18.1 (14.2-22.4) ml/kg/min, P=0.104] during 6MWT at W18 (Wilcoxon test). However, we observed significant reduction of BMI [27.7 (24.7-31) kg/m2 vs 27.7 (24.5-30.1) kg/m2, P=0.036], hip circumference [106 (94-109) cm vs 104 (93-109) cm, P=0.014], total-C [188 (170-223) mg/dl vs 186 (160-201), P=0.049] and HDL-C [45 (38-54) mg/dl vs 41 (36-51), P=0.045] (Wilcoxon test).

CONCLUSION: The technical problems affected training prescription and monitoring, failing to assess an improvement of CRF. However, the AP was useful to improve body composition and blood lipid profile.

WEIGHT-CLASS SPORTS AND SUSCEPTIBILITY TO UPPER RESPIRATORY TRACT INFECTION: A CROSS-SECTIONAL STUDY

SHIMIZU, S.

WASEDA UNIVERSITY

INTRODUCTION: BACKGROUND: Limited data on the relationship between weight-class sports and health are available. In particular, no studies have investigated the relationship between weight-class sports and upper respiratory tract infection (URTI) susceptibility.

PURPOSE: We conducted a cross-sectional study investigating the relationship between weight-class sports and susceptibility to URTI among Japanese past and present sports people.

METHODS: This study was conducted with monitors registered with an Internet research firm in Japan. The study participants consisted of 2,500 past or present sports people living in Japan. An Internet survey began on July 30, 2021, and ended on August 3, 2021. Participants were asked about the frequency of URTI before the COVID-19 a pandemic, and were asked to select the most appropriate answer among the following options: a few times each year, about once every year, once every few years and, rarely. Participants were also asked if they had ever participated or are currently participating weight-class sports (have participated in the past and currently participating [WCS-G]; have participated in the past but not currently [Past-WCS-G]; have never participated [No-WCS-G]). In addition, potential confounding factors that may be associated with URTI were investigated. We defined "a few times each year" and "about once each year" as frequent URTI sufferers and "once every few years" and "rarely" as non-frequent URTI sufferers. Multivariable-adjusted odds ratios (OR) and 95% confidence intervals (95% CI) for the susceptibility to URTI were obtained using logistic regression models while adjusting for confounders age, sex, marital status, household income, and education.

RESULTS: There were a total of 869 (34.8%) frequent URTI sufferers. Using the No-WCS-G as a reference, the OR and 95% CI were 1.53 (0.99–2.37) for Past-WCS-G, and 2.93 (2.30–3.72) for WCS-G, respectively.

CONCLUSION: The results of this study show that a negative relationship was observed between weight-class sports and URTI. Although this is a cross-sectional study and the study design cannot determine causal relationships, sports people

who play weight-class sports may need to be more careful in preventing URTI than those who play other sports. Therefore, the future studies are necessary to clarify the relationship between weight-class sports and URTI using a study design that can better establish the causal relationship between weight class sports and susceptibility to URTI.

RELATIONSHIP BETWEEN ANTERIOR-POSTERIOR ACCELERATION AND THE T2 RELAXATION TIME OF LUMBAR INTERVERTEBRAL DISCS DURING RUNNING EXERCISES

HAKKAKU, T., KUBO, Y., KOYAMA, K., NAKAZATO, K., HIRANUMA, K.

NIPPON SPORT SCIENCE UNIVERSITY

INTRODUCTION: There is limited knowledge about which loading protocols are beneficial to intervertebral discs (IVDs). The T2 relaxation time reflects the state of the IVD, and the length of the T2 relaxation time for lumbar IVDs is reportedly associated with loading patterns such as fast walking or slow running (1). These findings suggest that running exercise regimens affect IVDs; however, the detailed loading applied during running needs to be clarified. Reportedly, slow running is beneficial for IVDs, but the mechanism is unclear. Therefore, this study aimed to investigate the relationship between the load during slow running and changes in the T2 relaxation time of lumbar IVDs before and after running.

METHODS: Sixteen healthy male students were enrolled in this study (age, 20.8 ± 1.2 years; height, 172.2 ± 4.4 cm; weight, 72.3 ± 9.2 kg). The participants ran on a treadmill at a speed of 8 km/h for one minute. Running acceleration was recorded by a triaxial accelerometer with a belt fixed to the participant's L4/L5 lumbar intervertebral region. T2 values before and after the exercise were measured using MRI. For the measurement, the L4/L5 disc was divided into five regions of interest, designating the anterior annulus fibrosus (AF), anterior nucleus (AN), central nucleus (CN), posterior nucleus (PN), and posterior annulus fibrosus (PF). Pearsons correlation coefficient was used to examine the correlation between changes in the T2 relaxation time and acceleration.

RESULTS: The T2 relaxation time of the IVDs changed from their pre-running baseline values by +3.8% for AF, -2.6% for AN, -1.3% for CN, +0.2% for PN, and +7.5% for PF. The accelerations were 0.23 ± 0.06 rms in the X-axis (medial-lateral), 1.37 ± 0.08 rms in the Y-axis (vertical), and 0.30 ± 0.06 rms in the Z-axis (anterior-posterior). Analysis of the correlation between changes in the T2 relaxation time and acceleration showed a positive correlation between changes in the CN T2 relaxation time and acceleration in the Z axis ($r = 0.65$, $p = 0.006$).

CONCLUSION: In this study, a positive correlation was found between Z-axis acceleration and T2 relaxation time after running, suggesting that greater anterior-posterior acceleration increases the water content of the CN. This result supports the finding of previous studies that slow running results in the optimal range of loading for IVDs (1). However, as the running speed increases, the acceleration also increases (2), which may exceed the optimal loading range. Although high-speed running studies are necessary, the results suggest that anterior-posterior loading from slow-speed running may be related to changes in the water content of the CN.

TEMPORAL RELATIONSHIP BETWEEN OBJECTIVELY MEASURED PHYSICAL ACTIVITY AND PAIN OCCURRENCE IN PATIENTS WITH SICKLE CELL ANEMIA: A PILOT STUDY

NAKA, R., COLY MAME, S., DIAW, M., GADJI, M., SAMB, A., DIOP, S., FAYE FELIX, B., NADER, E., RANQUE, B., CHARLOT, K., CONNES, P., YOSHIDA, T., MIYACHI, M., TRIPETTE, J.

OCHANOMIZU UNIVERSITY

INTRODUCTION: Sickle cell anemia is caused by a mutation on the beta-globin gene, which leads to the production of abnormal hemoglobin. Under deoxygenated conditions, this hemoglobin may polymerize, causing red blood cells to adopt a sickle-like shape. Acute painful vaso-occlusive crises observed in sickle cell anemia patients result from the obstruction of vessels by sickled red blood cells. Since hypoxemia is one of the main triggers of red blood cell sickling, patients are usually recommended to avoid vigorous exercising. However, the adoption of sedentary lifestyles may prevent the development of physical activity-mediated adaptations that could have improved the clinical outcome of the disease. To date, only 2 studies have proposed an objective measurement of sickle cell anemia patients and none of them has been interested in the temporal relationship between physical behaviors and pain. The present study aims at exploring the temporal relationship between objectively assessed physical activity and pain occurrence in sickle cell disease patients.

METHODS: Eighty sickle cell disease patients were recruited through the National Center for Blood Transfusion of Dakar, Senegal for the "drePAnon" study (UMIN000042826, UMIN-CTR Clinical Trial). The participants were given a wrist-worn activity tracker equipped with an accelerometer and providing access to minute-by-minute physical activity data. The monitoring period lasted for 5 to 15 weeks. The participants also complete a pain diary. The data of 6 patients (male only, 30 ± 5 years old) with the highest quality of pain and physical activity data were used to perform the temporal statistical analysis. For each day of the monitoring period, 24 data features informing on the timing, duration, and volume of 3 and 6 MET or more physical activity over periods of 24, 48, and 72 hours were extracted from the minute-by-minute activity tracker time series. The temporal relationship between the principal components of the 24 physical activity parameters and pain was tested using cross-correlation tests for each patient and for time lags of 0 to -5 days.

RESULTS: Significant positive correlations between the principal component parameter of 3 and 6 MET or more physical activity and pain intensity were found in 3 of the 6 patients (correlation coefficients between 0.22 and 0.77). Interestingly, the strongest correlations (i.e., correlation coefficient above 0.70) occur for a time lag of -3 days.

CONCLUSION: The present study tends to confirm the potential temporal relationship between relatively high intensities of physical activity completed within the course of the daily life and later painful vaso-occlusive events. The risk of experiencing acute painful episodes on one given day may be related to physical behaviors that were performed 3 days before. Further studies are necessary to confirm these preliminary observations and to develop activity tracker-based preventive strategies against vaso-occlusive events.

A COMPARISON OF TWO BEST-PRACTICE CLINICAL EXERCISE SERVICES IN THE UNITED KINGDOM: RECOMMENDATIONS FOR SERVICE AND EDUCATION PROVIDERS

CROZIER, A., WATSON, P.M., GRAVES, L.E., GEORGE, K.P., RICHARDSON, D., NAYLOR, L., GREEN, D.J., ROSENBERG, M., JONES, H.

LIVERPOOL JOHN MOORES UNIVERSITY

INTRODUCTION: In the United Kingdom (UK), the National Health Service long-term plan advocates clinical exercise services, yet we have shown previously, clinical exercise provision is inconsistent across conditions in terms of job titles, roles and qualifications (Crozier et al., 2022). The creation of UK Clinical Exercise Physiologists (CEPs), as a registered health professional in 2021, provided a solution to standardise the exercise workforce. Our aim was to compare common themes across two nationally recognised best-practice clinical exercise services in terms of staff knowledge and skills to generate common themes to translate into consistent, evidence-based, actionable recommendations.

METHODS: A multi-method qualitative (semi-structured interviews, focus groups, observations, field notes and researcher reflections) approach was employed with the researcher immersed for 12-weeks within each service (cancer service delivered from a community setting and cardiac service delivered in dedicated acute setting). The Consolidated Framework for Implementation Research (CFIR) was used as an overarching guide. Data from each service were thematically analysed individually before synthesis to compare generated themes from staff and service user perspectives. Clinical exercise service staff recruited (n=17) were comprised of registered Clinical Exercise Physiologists (CEPs) (n=5), unregulated advanced exercise instructors (n=7), clinical nurse specialists (n=2), dieticians (n=1) and service managers/leads (n=2). Service users recruited (n=16) attended either one of the exercise services following a clinical event or diagnosis.

RESULTS: There were five common themes identified across the two services: (i) registered CEPs (or those qualified to a level to apply for registration via equivalency) were employed, (ii) nationally recognised exercise referral pathways were followed from the initial point of care and referral for exercise was to a CEP (iii) workplace craft and peer observation were essential for the sharing of knowledge and experiences between different health professions (iv) flexible behaviour change approaches via impromptu conversations were more successful at engaging patients than structured education sessions, and (v) individualised and innovative evidence-based exercise prescription was optimal.

CONCLUSION: The themes outlined in this study suggest that clinical exercise services should employ registered CEPs. The knowledge and skills CEPs possess including innovative, evidence based-exercise prescription, flexible behaviour change approaches, referral pathways and communication with other health care professionals, ensure effective clinical exercise services. Education and continued professional development of CEPs should include workplace specific training and observations. The themes from this study align with the Clinical Exercise Physiology UK curriculum framework to ensure CEPs are trained to meet the standards for registration.

TRAINING EXERCISE AND SPORT PROFESSIONALS TO SUPERVISE EXERCISE PROGRAMS TAILORED TO PREGNANT AND POSTPARTUM WOMEN: THE ACTIVE PREGNANCY PROJECT WORKSHOPS AND EDUCATIONAL RESOURCES

SANTOS-ROCHA, R., SZUMILEWICZ, A.

SPORT SCIENCES SCHOOL OF RIO MAIOR - POLYTECHNIC INSTITUTE OF SANTARÉM

INTRODUCTION: Physical activity should be part of a healthy lifestyle during pregnancy and postpartum. Current literature supports the recommendation to initiate or continue physical exercise in pregnant and postpartum women without complications. Despite evidence of multiple health and fitness benefits to mother and foetus of being active during pregnancy and postpartum, most women reduce both frequency and intensity of exercise, and many are inactive throughout, failing to meet recommended physical activity levels. Therefore, promoting physical activity and exercise among women of childbearing age remains a priority in public health policy, and it is a challenging process. Women's health literacy is essential to improve healthcare behavior, empowerment, and self-management. Thus, educating exercise and health professionals effectively is of major importance.

The objective is to present one of the outcomes of the Active Pregnancy Project regarding the educational programs, resources, and professional standards for exercise and sports professionals dealing with pregnant and postpartum women.

METHODS: This session will present a qualitative analysis regarding the development, feasibility, and effectiveness of educational interventions and contents, as well as European professional standards for exercise and sports professionals, based on updated guidelines and evidence on the positive impact of exercise during pregnancy and postpartum.

The main methods were: conducting systematic reviews; validating the exercise program as a complex intervention in health; developing educational standards and training for the Pre/Post Natal Exercise Specialist; developing educational tools, such as webinars, workshops, guidelines, and textbook (e.g. Exercise and Physical Activity during Pregnancy and Postpartum, by Springer) and manuals (e.g., Active Pregnancy and Health Professionals' Guides) for women and professionals; developing the free access Active Pregnancy YouTube channel: https://www.youtube.com/channel/UC0Vyookwc0mcQ5T70imtoNA/playlists.

RESULTS: The educational program and materials developed within the Active Pregnancy Project effectively educate exercise and sports professionals to work with pregnant and postpartum clients. They will be professionally prepared to consider the multifaceted determinants and outcomes of prenatal physical activity and intervene to promote physical activity before, during, and after pregnancy, helping women to overcome any identified barriers.

CONCLUSION: Trustworthy and comprehensive guidelines created based on the Active Pregnancy Project and international and interdisciplinary initiatives should be disseminated among all interested in prenatal physical activity: pregnant women and their families, obstetric care providers, and exercise professionals to enable them effective cooperation and to globally promote exercise in pregnancy.

EVALUATION AND TREATMENT OF THORACIC HYPERKYPHOSIS IN YOUNG BASKETBALL PLAYERS: A PILOT STUDY

MERONI, A., POCATERRA, M., GALVANI, C., BRUSEGHINI, P.

UNIVERSITÀ CATTOLICA DEL SACRO CUORE

INTRODUCTION: Thoracic hyperkyphosis is one of the most common postural disorders (Garoflid, 2000) identified with a rounded back and shoulders forward (Vaughn, 2007) that could be developed during adolescence (Kamaci, 2015). Young basketball players have a high level of endurance demand, often overloading the biological tissues and causing biomechanical compensations (Guedes, 2014). Due to the immaturity of their musculoskeletal structures, those consequences may influence the growth process and lead to the development of various postural patterns (Grabara, 2014). The following study aims to verify if the use of a corrective program could prevent postural disorders in young basketball athletes.

METHODS: Twenty-eight healthy male adolescents basketball players took part in the study: fourteen in the experimental (EXP) group (15.3±1.1yrs; 65.9±9.1 kg; 182.5±6.2 cm) and fourteen in the control (CTRL) group (15.4±1.3 yrs; 73.9±6 kg; 180.8±7.5 cm). Both groups were assessed with a postural screening test in order to find any postural issues and subjects were screened with manual inclinometers and plumb line (Kendall, 2005). At baseline (PRE) and post 8 weeks of training (POST), Dorsal Kyphosis grades (DK), Forward Head Posture grades (FHP), Forward Shoulder Position anteposition (FSP), and Push-Pull ratio (PPratio) have been evaluated. The training program was structured with three parts: the first with mobility exercises for the upper joints, the second with analytical exercises for the shoulder musculature, and a third with integrated exercises for the upper musculature.

RESULTS: In the EXP group, DK (PRE 45.8±5.3°; POST: 36.1±7°), FHP (PRE: 12.9±5.6°; POST: 3.3±3.4°), FSP (PRE: 12.9±1.5 cm; POST: 11.1±1.4 cm), and PPratio (PRE: 2.73±1.24; POST: 1.54±0.34) were significantly ($p<0.01$) influenced by training. In the CTRL group, there weren't any significant changes in the data except for the FSP (PRE: 12.3±1.3 cm; POST: 13.1±1.6 cm) ($p<0.05$).

CONCLUSION: Our data show that a corrective exercise program could improve dorsal kyphosis posture, lowering the entity of the dorsal and cervical curves, realigning the head and the shoulders in the correct position, and balancing the muscular strength differences between pushing and pulling muscles. The present corrective exercise program could be used as a pre-practice warm-up in those athletes who have a kyphosis posture or in those athletes with a kyphosis that needs to be corrected.

ASSOCIATIONS BETWEEN PHYSICAL ACTIVITY, CARDIORESPIRATORY FITNESS, PERCEPTUAL-COGNITIVE FUNCTION, AND DEPRESSIVE SYMPTOMS IN YOUNG ADULTS

MOSS, S.J., ENSLIN, L., KRUGER, A., CZYZ, S.H.

NORTH-WEST UNIVERSITY

INTRODUCTION: Depression is a global health pandemic, particularly affecting young adults, and can result in cognitive impairment, premature mortality, and various other physical and mental health issues. However, limited research exists on the relationship between objective habitual physical activity, cardiorespiratory fitness, perceptual-cognitive functioning and depression in young adults. This study aimed to examine the relationship between these variables in young South African adults aged 18-25 years.

METHODS: Forty young adults between 18-25 years (21.8 ± 1.76 years) were included in this study, with a majority female (90%). The Beck Depression Inventory (BDI) evaluated depressive symptoms, and a combination of heart rate and accelerometry (ActiHeart®) measured objective habitual physical activity levels over seven consecutive days. Cardiorespiratory fitness was calculated from an incremental step test. Multi-object tracking measurements (NeuroTracker®) represented perceptual-cognitive functioning and screen time was measured using a log sheet. . Partial correlation analyses, multiple regression analysis and Pearson's Chi-squares were utilized to determine the relationship between objective habitual physical activity, cardiorespiratory fitness, perceptual-cognitive functioning, and depressive symptoms.

RESULTS: The average BDI-score was 20.5 ± 8.0 points for the participants. Results showed no significant association between objectively measured habitual physical activity and symptoms of depression ($r = 0.002$; $p = 0.989$), nor between cardiorespiratory fitness and symptoms of depression ($r = -0.13$; $p = 0.43$). There was, however, a significant negative correlation between symptoms of depression and perceptual-cognitive functioning($r = -0.34$; $p = 0.05$), and a significant positive correlation between symptoms of depression and leisure screen time ($r = 0.35$; $p = 0.03$) when adjusted for sex and age.

CONCLUSION: Individuals engaging in longer periods of leisure screen time showed higher scores of depressive symptoms, as well as lower perceptual-cognitive functioning. Although not statistically significant, trends of an inverse association were evident between habitual physical activity and depressive scores. Introducing regular exercise may serve as a low-cost intervention in the management of depressive symptoms in young adults. Replacing screen time with regular physical activity may improve depressive symptoms, improve cardiorespiratory fitness and perceptual cognitive functioning.

CROSS-SECTIONAL ASSOCIATIONS OF ACCESS TO PARKS WITH TIMING-SPECIFIC PHYSICAL ACTIVITY AND SEDENTARY BEHAVIOR IN OLDER ADULTS

LIAO, Y.

NATIONAL TAIWAN NORMAL UNIVERSITY

INTRODUCTION: Parks play important roles to promote physical activity among older adults, however, it remains unclear its associations with physical activity and sedentary behavior depending on the time of the day. Thus, this study examined whether access to parks is associated with timing-specific physical activity and sedentary behavior in older adults.

METHODS: We included 214 older adults (mean age: 80.2 ± 7.0 years) from Taiwan in this cross-sectional study. Assess to parks within 400-, 800-, and 1600-m of participants' residential address were estimated using a geographic information system. An accelerometer (Actigraph) was used to calculate their daily physical activity and sedentary behavior during three time periods: morning (6:00 to 12:00), afternoon (12:01 to 18:00), and night (18:01 to 24:00). Multiple linear regression was performed after adjustment for potential covariates to examine the associations of park accessibility with physical activity and sedentary behavior during different time periods.

RESULTS: After adjusting for confounders, favorable access to parks within 400-m buffer is positively associated with older adults' total physical activity in afternoon (B = 3.00; 95% CI, 1.25 - 4.75) and evening (B = 2.42; 95% CI, 0.84 - 4.00), as well as negatively related to sedentary time in afternoon (B = -3.00; 95% CI, -4.75 - 1.25) and evening (B = -2.42; 95% CI, -4.00 - -0.84). Above-mentioned associations were found within 800-m buffer, but not in 1600-m buffer. No association was found between access to parks and older adults' physical activity and sedentary behavior during morning.

CONCLUSION: Regardless of 400-, and 800-m buffer, favorable access to parks in the neighborhood is positively associated with older adults' total physical activity and negatively related to their sedentary time in afternoon and evening. Future research applying longitudinal methods is required to further understand these associations.

GET STRONG TO FIGHT CHILDHOOD CANCER: AN EXERCISE INTERVENTION FOR CHILDREN AND ADOLESCENTS UNDERGOING ANTI-CANCER TREATMENT (FORTEE)

DREISMICKENBECKER, E., LANFRANCONI, F., NEU, M.A., STÖSSEL, S., PLOCH, L., PAUL, N.W., RUCKES, C., BALDUZZI, A., BRIGHT, P., WINDSOR, S., WISKEMANN, J., EL-RAJAB, I.

UNIVERSITY OF MEDICINE JOHANEES GUTTEMBERG-UNIVERSITY OF MAINZ

INTRODUCTION: Picmanova, V., Heisserer , B., Mongondry, R., Bloch, W., Rizvi, K., Fridh, M.K., Lucia, A., Fiuza-Luces, C., Götte, M., Spreafico, F., Konda, B., Stefanovic, M., Sowa-Israel, M., Baader, T., Faber, J.

Cancer is the leading cause of death by non-communicable diseases in children in Europe. During cancer treatment, patients' morbidity is increased due to e.g. physical inactivity and cancer-related fatigue. Personalised exercise training during the intensive phase of cancer treatment in children and adolescents is a promising therapy to mitigate above mentioned issues. However, evidence for

using exercise to counteract fatigue and improve health-related quality of life is lacking in paediatric oncology.

The FORTEe research project intends to evaluate a personalised and standardised exercise intervention in 450 children, adolescents and young adults undergoing cancer treatment in nine centres across Europe. This randomised, controlled multicentre trial aims to generate high evidence for an innovative, patient-centred exercise treatment as part of the standard of care. Experiences

and expertise in paediatric exercise oncology within Europe were merged to develop specific exercise training and testing protocols which are to be implemented with the help of digital, innovative technologies.

The elaborated protocols are standardised to enable adapted personalised exercise training. A meticulous approach to tailored exercise includes a sensitive functional evaluation system to set the appropriate exercise dosage, aiming atdefining type, frequency and intensity. Precision exercise training protocols are adapted and personalised to the cancer patient □ ́s clinical phenotype. The

intensity, time and volume of exercise are adjusted to the cancer treatment intensity and to each patient ́s clinical condition and response. For this purpose, different modalities are included that allow training sessions in-person but also

remotely, supported by innovative technologies.

As a progress beyond the current state-of-the-art, FORTEe has the ambition to implement paediatric exercise oncology as an evidence-based standard in clinical care for all childhood cancer patients worldwide.

EXERCISE-INDUCED REDUCTIONS IN MITOCHONDRIAL ADP SENSITIVITY ARE LINKED TO MUSCLE GLYCOGEN DEPLETION

PETRICK, H.L.1,2, FUCHS, C.J.1, HERMANS, W.J.H.1, HENDRIKS, F.K.1, BELS, J.L.M.1, SENDEN, J.M.1, HOLLOWAY, G.P.2, VAN LOON, L.J.C.1

<1> MAASTRICHT UNIVERSITY MEDICAL CENTRE+, MAASTRICHT, THE NETHERLANDS <2> UNIVERSITY OF GUELPH, GUELPH, CANADA

INTRODUCTION: Mitochondrial oxidative phosphorylation is dependent on the supply of substrates such as ADP. While the sensitivity of mitochondria to ADP is acutely impaired in response to exercise, the mechanisms and physiological consequences remain unknown. It is possible that the decline in mitochondrial ADP sensitivity could concentrate ADP within the cytosol, and since cytosolic ADP activates glycogen phosphorylase, this could be a mechanism to promote glycogen breakdown. Despite this possibility, the relationship between mitochondrial substrate sensitivity and the extent of glycogen depletion during exercise remains to be understood.

METHODS: 12 endurance-trained male cyclists (25 ± 5 years, VO2max: 66 ± 5 mL/kg/min) performed a standard ~2 hour glycogen depletion protocol on a cycle ergometer in a fasted state. The protocol consisted of 2 min blocks alternating between high and low intensity cycling. The high intensity blocks started at 90% Wmax and were decreased by 10% Wmax (80%, 70% Wmax) when intervals were no longer able to be completed (60 rpm). The low intensity blocks were performed at 50% Wmax. Muscle biopsies were obtained pre-exercise and 2 hours post-exercise. Mitochondrial ADP sensitivity (Michaelis-Menten kinetics, Vmax constrained at 105) and pyruvate sensitivity (one-phase association, plateau constrained at 100) were measured in permeabilized muscle fibres. Muscle glycogen content was determined in freeze-dried whole muscle homogenate. Data were analyzed using paired t-tests and expressed as mean ± SD.

RESULTS: The glycogen-depleting cycling protocol decreased muscle glycogen content nearly 3-fold (226 ± 44 mmol/kg dry weight pre- vs. 77 ± 39 mmol/kg dry weight post-exercise, $p < 0.0001$). While exercise did not alter maximal mitochondrial respiratory capacity, mitochondrial ADP sensitivity was decreased ~12%, indicated by an increase in the apparent Km (1098 ± 102 µM ADP pre- vs 1229 ± 127 µM ADP post-exercise, $p = 0.0008$). In contrast, mitochondrial pyruvate sensitivity was increased post-exercise (half-time: 98 ± 13 µM pyruvate pre- vs 92 ± 8 µM pyruvate post-exercise, $p = 0.03$), suggesting an increase in the ability to utilize glycogen for oxidative phosphorylation. While no significant correlation was found between changes in pyruvate sensitivity and the decline in muscle glycogen content, in contrast, the change in the ADP Km was significantly correlated ($r = -0.60$, $p = 0.04$) with the extent of glycogen depletion.

CONCLUSION: The present data suggest the exercise-induced decrease in mitochondrial ADP sensitivity is a mechanism promoting glycogen breakdown during prolonged intense exercise in human skeletal muscle.

RELATIONSHIP BETWEEN MITOCHONDRIAL RESPIRATORY VARIABLES AND CONVENTIONAL DETERMINANTS OF ENDURANCE EXERCISE PERFORMANCE IN HEALTHY ADULTS

ACTON, J.P., ALSHARIF, N.S., COCKSEDGE, S.P., PEDEN, D.P., FERGUSON, R.A., MITCHELL, E.A., BAILEY, S.J.

LOUGHBOROUGH UNIVERSITY, UNITED KINGDOM

INTRODUCTION: It is well documented that exercise economy, lactate or gas exchange threshold, and VO2peak are important determinants of endurance exercise performance. However, the extent to which these systemic endurance performance determinants relate to local muscle respiratory function is comparatively unclear. Therefore, the purpose of the current study was to assess the extent to which skeletal muscle mitochondrial respiratory variables were associated with the classical determinants of endurance exercise performance.

METHODS: Eighteen recreationally-active (VO2peak, 47 ± 5 ml/kg/min) male participants reported to the laboratory on two separate occasions. On the first visit to the laboratory, participants completed a linear ramp incremental cycle test, at rate

of 30 W/min, until exhaustion. Pulmonary gas exchange and ventilatory variables were collected throughout the test for later determination of peak aerobic power (PAP), gas exchange threshold (GET), respiratory compensation point (RCP), VO2-work rate (VO2-WR) slope (as a marker of exercise economy), and VO2peak. On the second visit to the laboratory, a muscle biopsy was obtained from the m. vastus lateralis for determination of mitochondrial respiratory variables in permeabilised muscle fibre bundles. Specifically, uncoupled leak respiration through complex I (CIL), saturating adenosine diphosphate stimulated respiration through complex I (CIP) and complex I+II (CI+IIP), and maximal electron transfer system activity through complex I+II (CI+IIE), complex II (CIIE) and complex IV (CIVE) were assess using high-resolution respirometry. In addition, coupling control ratio (CIL/CI+IIP; 1/RCR) was used as a marker of oxidative phosphorylation coupling efficiency. The relationship between the variables determined through the ramp incremental test and high-resolution respirometry were assessed using Pearson's correlation coefficient (r) with statistical significance accepted as P≤0.05.

RESULTS: There were negative relationships between 1/RCR and PAP (r = -0.52), GET (r = -0.59), RCP (r = -0.50) and VO2peak (r = -0.47), as well as CIL and PAP (r = -0.57) and GET (r = -0.61). There was a positive relationship between CIVE and VO2peak (r = 0.47), and CIIE and RCP (r = 0.46). There were no further significant correlations between variables obtained from the ramp incremental exercise test and high-resolution respirometry.

CONCLUSION: Oxidative phosphorylation coupling efficiency, inferred from the 1/RCR coupling control ratio, was inversely associated with established determinants of endurance exercise performance. These observations suggest that improved mitochondrial oxidative phosphorylation coupling efficiency is associated with higher physiological thresholds which may have implications for enhancing endurance exercise performance.

THE COMBINED TREATMENT OF VITAMIN E SUPPLEMENT AND VOLUNTARY WHEEL RUNNING ENHANCES SKELETAL MUSCLE MITOCHONDRIAL FUNCTION INDEPENDENT OF OXIDATIVE STRESS IN OVARIECTOMIZED MICE

TAN, Y.1, PARK, K.1, YOON, H.1, PARK, S.1, RYU, B.1, SO, B.2, JANG, J.2, PARK, J.2, LEE, K.2, YEOM, D.2, KWAK, D.3, KANG, C.2, PARK, Y.1

1. INCHEON NATIONAL UNIVERSITY, 2. INHA UNIVERSITY, 3. HANYANG UNIVERSITY

INTRODUCTION: Menopausal women experience obesity mainly due to skeletal muscle metabolic dysfunction. During exercise, skeletal muscle fibers consume greater oxygen compared to resting state contributing to the unbalanced state of increased oxidative stress, which can be alleviated by vitamin E supplement, one of the strong insoluble antioxidants. The findings from previous studies investigating the effect of vitamin E combined with exercise are somewhat mixed. The purpose of the present study was to investigate whether the combined treatment of vitamin E supplement and voluntary wheel running can enhance metabolic function including skeletal muscle mitochondria in ovariectomized mice, and whether this improvement is associated with lower oxidative stress marker.

METHODS: This 12-week study used female C57BL/6J wild type mice (n=40, 8 weeks old), which were randomly assigned to Sham (SHM), ovariectomy (OVX), ovariectomy with exercise (OVXVE), ovariectomy with vitamin E (OVXV), and ovariectomy with exercise and vitamin E (OVXVE) groups. Fat/lean mass and whole-body metabolic rate were assessed using dual-energy x-ray absorptiometry (DXA) and indirect calorimetry, respectively. Mitochondrial function and PGC1α protein content were assessed using OROBOROS O2K and Western blot. Carbonyl protein content, a marker of oxidative stress, was measured by protein carbonyl assay kit.

RESULTS: Lean mass did not differ between groups, but in fat mass, OVXV and OVXVE were significantly higher than SHM, and OVXVE was higher than OVX and OVXE. The metabolic rate was significantly greater in SHM than other groups. While mitochondrial function in gastrocnemius muscle was not significantly different between groups, interestingly in soleus, OVXVE was significantly greater than SHM, OVX, and OVXE (82.7±5.7, 87.9±5.4, 90.4±5.1, and 112.2±5.4 pmol*sec-1*mg-1, all P<0.05, SHM, OVX, OVXE, and OVXVE, respectively). This trend was confirmed by the assessment of PGC1α protein content in soleus, such that only OVXVE was significantly greater than SHM and OVX groups. However, protein carbonyl content was lower in OVXV and OVXVE compared to OVX in gastrocnemius, whereas there was no significant group difference found in soleus.

CONCLUSION: The combined treatment with vitamin E and exercise enhanced mitochondrial function and PGC1α protein content of soleus skeletal muscle, which was independent of oxidative stress marker. More studies are necessary to investigate the underlying mechanism by which the synergetic effect of vitamin E and exercise treatment on mitochondrial function differs between soleus and gastrocnemius muscles in ovariectomized mice.

MITOCHONDRIA OF HUMAN TYPE II MUSCLE FIBERS HAVE HIGHER A INTRINSIC RESPIRATORY RATE WHICH IS MEDIATED THROUGH ELEVATED COMPLEX II RESPIRATION.

APRÓ, W., FLOCKHART, M., LARSEN, F., EDMAN, S.

THE SWEDISH SCHOOL OF SPORT AND HEALTH SCIENCES

INTRODUCTION: Human skeletal muscle consists of a mixture of slow- and fast-twitch fibers with distinct capacities for contraction mechanics, glycolysis, and oxidative phosphorylation (OXPHOS). While the divergence in mitochondrial volume favoring slow-twitch fibers is well established, data on the fiber type-specific intrinsic mitochondrial function are highly limited with existing data mainly being generated in animal models. However, translating animal models comparing oxidative (I/IIA) to glycolytic (IIX/IIB) fibers onto human physiology is difficult, given that our muscles consist of mainly slow or fast-twitch oxidative fibers (I/IIA) with limited glycolytic (IIX) fiber content. This highlights the need for more human data on the topic.

METHODS: Skeletal muscle biopsies were collected from seven young and healthy men and women in a fasted state. Immediately after collection, individual muscle fibers were dissected from the whole muscle tissue, fiber typed using the newly developed THRIFTY-method and subsequently pooled according to their fiber type. The whole procedure from sample collection, dissection, typing, and pooling took 5-6 hours. The type I and type II muscle fibers pools were then permeabilized with saponin followed by measurement of mitochondrial respiration using a two-channel high-resolution Oroboros respirometer. A median of 48 (range 15-52) type I and 31 (21-54) type II fibers were included per participant in the respiratory measurement following fiber typing, with 285 slow-twitch fibers and 232 fast-twitch fibers included across all participants. To account for mitochondrial volume in each fiber pool, samples were recovered from the respirometer chambers and analyzed for mitochondrial volume markers residing in both the outer and inner mitochondrial membranes using immunoblotting.

RESULTS: As expected, full ADP stimulated respiration, i.e. OXPHOS capacity was higher in the slow-twitch type I fibers (59 vs 47 pmol x s-1 x mg-1, $P<0.05$) and assessment of mitochondrial volume markers revealed approximately 3-fold higher mitochondrial content in the type I fiber pools. When expressed per mitochondrial volume, type II fibers had approximately 50% higher ($P<0.05$) respiration compared to type I fibers. No difference in the respiratory rates were observed during states of both fat oxidation and complex I capacity between the mitochondria of type I and type II fibers. However, when the combined respiration of complex I and complex II were related to only complex I respiration, values were significantly higher in type II fibers. Moreover, type II fibers had 2-fold higher complex II protein levels compared to type I fibers ($P<0.05$).

CONCLUSION: Mitochondria of human type II muscle fibers compensate for their lack of volume by increasing the expression of key proteins regulating OXPHOS capacity. Human fast-twitch mitochondria also have a substantially elevated intrinsic respiratory rate which is primarily mediated through elevated complex II respiration.

THE INFLUENCE OF SEX ON FIBER-SPECIFIC SKELETAL MUSCLE CHARACTERISTICS LINKED TO AEROBIC ENERGY METABOLISM

BAILLEUL, C., HODSON, N., ABOU SAWAN, S., KUMBHARE, D.A., MOORE, D.R., GILLEN, J.B.

UNIVERSITY OF TORONTO

INTRODUCTION: Increased fat oxidation reported during moderate-intensity endurance exercise in females compared to males may be due, in part, to sex differences in resting skeletal muscle characteristics. For example, females have been demonstrated to have greater whole-muscle mitochondrial content (1) and capillarization (2), which may be explained by a higher proportionate area of slow-oxidative type I fibers compared to males. However, it is also possible that the oxidative potential of type I and II muscle fibers is elevated in females, but this has yet to be explored. The purpose of this study was to investigate the influence of sex on human skeletal muscle fiber composition and fiber-specific indices of mitochondrial content and capillarization. The secondary objective was to investigate sex differences in biomarkers of mitochondrial content, mitochondrial dynamics, and fat metabolism in whole muscle homogenates.

METHODS: Resting skeletal muscle biopsy samples from the vastus lateralis were collected from untrained females (n=14; 23±5yr, 23.3±3.2kg/m2) and males (n=13; 23±4yr, 23.1±2.4kg/m2). Through immunofluorescent analyses we determined type I, IIa, and IIx fiber-type distribution, proportionate area and cross-sectional area (CSA), as well as fiber-type specific mitochondrial content and capillarization. Fiber-type specific mitochondrial content was quantified via COX IV pixel intensity of type I and II fibers. Fiber-type specific capillarization was determined via quantification of CD31-labelled capillaries and calculation of capillary-to-fiber ratio, capillary-to-fiber perimeter exchange index and capillary density of type I and II fibers. Western blot analysis was performed on whole muscle homogenates for determination of protein content of markers related to mitochondrial content (COXIV), mitochondrial dynamics (MFN2, DRP1) and fat metabolism (β-HAD).

RESULTS: Compared to males, females had increased proportionate area of type I fibers (42±12 vs 29±10%, p=0.01) and decreased proportionate area of type IIa fibers (39±6 vs 49±13%, p=0.02). The CSA of type IIa (5774±1146 vs 4183±1068 µm2, p=0.003) and IIx (4424±1380 vs 2744±688 µm2, p=0.002) fibers were greater in males compared to females. There were no sex differences in indices of capillarization or mitochondrial content among type I or type II fibers ($p>0.05$). However, increased capillary density of type I vs type II fibers was observed in males only (364±88 vs 280±66 capillaries/mm2; $p<0.05$). There were no sex differences in whole-muscle COX IV, DRP1, MFN2, and β-HAD protein content ($p>0.05$).

CONCLUSION: Our results suggest that a greater proportionate area of type I muscle fibers in females, rather than sex differences in the oxidative potential of type I or type II fibers, may contribute to previously reported sex differences in substrate metabolism during endurance exercise.

INCREASED BLOOD LACTATE LEVELS VIA VENOUS INFUSION REDUCES CIRCULATING FREE FATTY ACIDS IN HUMANS AT REST

MOBERG, M., APRÓ, W.

SWEDISH SCHOOL OF SPORT AND HEALTH SCIENCES

INTRODUCTION: Several lines of evidence, from in vitro and rodent based research, suggests that lactate possess hormonal-like properties in a number of tissues. Here, one of the most highlighted tissues is adipose tissue, where elevated lactate exposure is described to suppress lipolysis. Through binding to the G-protein coupled receptor 81 (GPR81), lactate

stimulates a reduction in cyclicAMP and thus suppresses lipolysis. The half maximal effective concentration (EC50) for lactate stimulation of GPR81 is described to range between 1.5 to 5 mM depending on experimental condition. The hormonal-like properties of lactate in humans in vivo are however largely unexplored. Accordingly, the objective of this study was to study the signaling properties of lactate in adipose tissue in humans at rest, with focus on the regulation of lipolysis.

METHODS: Twelve young healthy individuals (six male and six female) took part in two experimental trials in which they received a venous infusion of sodium lactate (125 µmol/kg fat free mass/min) or volume matched saline, in a randomized cross-over fashion. Experiments were performed in the morning, with subjects in the over-night fasted state. Following baseline blood sampling and subcutaneous adipose tissue biopsy sampling, venous infusion was performed for 60 min. Blood samples were taken every 10 min during infusion and 15, 30, 45, 60, 90 and 120 min after infusion. Additional subcutaneous adipose tissue biopsies were taken immediately and 60 min after infusion. Blood samples were immediately analyzed for lactate, pH, sodium, potassium, base excess and hematocrit using automated systems. Serum levels of free fatty acids (FFA) were quantified using an enzymatic spectrophotometric assay.

RESULTS: The sodium lactate infusion increased blood levels of lactate from 0.6±0.1 mM at rest to 5.4±0.2 mM after 60 min of infusion and returned to baseline levels at 90 min post infusion. During saline infusion blood lactate levels decreased from 0.7±0.1 mM at rest to <0.5 mM after infusion. Based on changes in hematocrit there was an approximate 5% plasma volume expansion in both trials. Average baseline serum levels of FFA were 0.57±0.21 mM in both trials. In the saline trials serum FFA decreased by 10% after 60 min of infusion but returned to baseline 120 min post infusion. In the lactate infusion trials serum FFA were reduced by 40% immediately after infusion and remained 20% below basal levels at 120 min post infusion

CONCLUSION: Moderately elevated blood lactate levels, achieved by venous infusion, in humans at rest significantly reduces serum levels of FFA. We propose that this effect is due to lactate-GPR81 signaling in adipose tissue that inhibits lipolysis.

EFFECTS OF ANAEROBIC LACTIC METABOLISM ON THE SLOW COMPONENT OF OXYGEN UPTAKE KINETICS DURING HIGH INTENSITY EXERCISE IN HUMANS

BARILARI, C., BELLUCCI, M., TABONI, A., VINETTI, G., FAGONI, N., FERRETTI, G.

UNIVERSITY OF BRESCIA

INTRODUCTION: The origin of the slow component of the oxygen uptake kinetics, which appears during exercise above the critical power and the maximal lactate steady state, is still a matter of discussion. Among the various hypotheses, Capelli et al (Eur J Appl Physiol 66: 189-195, 1993) postulated that, during intense exercise, the progressive decrease of muscle pH may be responsible for the slow component. In fact they showed that, during prolonged exercise, the intensity of which was betweeen 60 and 80% of VO2max, the rate of oxygen uptake increase after the 5th min of exercise was directly proportional to that of blood lactate accumulation. If this statement was correct, we would expect 1) a linear relationship between the amplitude of the slow component and the changes in blood lactate concentration during exercise, and 2) a slope of this linear relationship corresponding to the energy equivalent of blood lactate accumulation. Aim of the present study was to test the above hypotheses.

METHODS: On 13 male subjects (age 25 +/- 6 years, body mas 73 +/- 7 kg, height 178 +/- 7 cm), who performed tests at 60, 65, 70 and 80 % of individual VO2max up to exhaustion, we measured oxygen uptake (VO2) breath-by-breath, and blood lactate concentration ([La]b) at rest, and during exercise at min 5, 10, 20, 30 and at exhaustion. The volume of oxygen (DVO2) above the maximal power at steady state for VO2 and [La]b was then calculated, assuming that the slow component starts at the beginning of exercise and that the VO2 increase due to the slow component is linear, in agreement with the tested hypotheses.

RESULTS: At maximal lactate steady state, power was 176 +/- 24 W and VO2 corresponded to 64 +/- 5 % of individual VO2max. The linear relationship between DVO2 and [La]b was described by the following equation: $y = 2.90 x + 13.33$, $r = 0.77$. The intercept was slightly but significantly higher than 0. The slope fell inside the expected values for the energy equivalent of blood lactate accumulation.

CONCLUSION: These results appear substantially in agreement with the tested hypotheses. The highly significant linear relationship between DVO2 and [La]b was characterised by a slope corresponding to the energy equivalent of blood lactate accumulation indeed (Ferretti G, Energetics of Muscular Exercise, Springer, 2015). Since lactate accumulation at powers higher than that yielding the maximal lactate steady state occurs in a substantially linear manner, this may justify indeed a linear treatment of the time course of the slow component of oxygen uptake kinetics during high-intensity exercise, as done in this study.

THE IMPACT OF RAMP SLOPE ON THE NEAR-INFRARED SPECTROSCOPY DEOXYHEMOGLOBIN BREAKPOINT AND THE RESPIRATORY COMPENSATION POINT

INGLIS, E.C., FLEITAS-PANIAGUA, P., AZEVEDO, R., MURIAS, J.M.

UNIVERSITY OF CALGARY

INTRODUCTION: Near-infrared spectroscopy (NIRS) has become a commonly used, non-invasive technique to gain insight into muscle oxygenation responses. During ramp-incremental (RI) cycling exercise, the deoxygenated hemoglobin ([HHb]) NIRS signal in the vastus lateralis demonstrates a plateau-like response in the latter portion of the test. This response,

named the [HHb] breakpoint ([HHb]BP), has been shown to be repeatable measure that corresponds to exercise intensity at the respiratory compensation point (RCP). While studies have investigated the impact of variables such as pedalling rate, fraction of inspired oxygen, and fitness status on oxygen uptake (VO2) at the [HHb]BP and its correspondence to the RCP, the impact of RI slope has not been examined. Therefore, this study aimed to determine whether the VO2 at which the [HHb]BP and RCP occur is affected by variations in RI slope. We hypothesized that, due to the physiological nature of the [HHb]BP, the VO2 at which the [HHb]BP and RCP occur would not be different between tests.

METHODS: Twelve healthy participants (9 M, 3 F) reported to the laboratory on three separate occasions to perform a RI cycling exercise test to task failure. Each test consisted of a 4-min baseline at 20W, followed by a 6-min moderate intensity square-wave transition to 60-80 W, and 4-min at 20W before a RI test with a slope of 15, 30 or 45 W/min. The order of testing was randomized for each participant, and each visit was separated by 48-72 hours. The NIRS derived [HHb] signal in the vastus lateralis as well as VO2 were continuously measured throughout each test.

RESULTS: VO2 at the [HHb]BP was not different between slopes at 3.08 ± 0.53 L/min, 3.10 ± 0.68 L/min, and 3.04 ± 0.64 L/min for the 15, 30 and 45 W/min slope, respectively ($p>0.05$). VO2 at the RCP was 3.16 ± 0.65 L/min (15 W/min), 3.20 ± 0.73 L/min (30 W/min), and 3.17 ± 0.75 (L/min) with no difference between slopes ($p>0.05$). There were no differences between VO2 at the [HHb]BP and the RCP for any of the RI slopes ($p>0.05$). Correlation values, bias, and confidence intervals (CI) between the VO2 at the [HHb]BP and RCP were: $r=0.91$ ($p<0.01$), bias -0.08 L/min ($p=0.34$), CI -0.25 to 0.19 (15 W/min); $r=0.97$ ($p<0.01$), bias -0.10 L/min ($p=0.10$), CI -0.22 to 0.02 (30 W/min); and $r=0.88$ ($p<0.01$), bias -0.12 L/min ($p=0.26$), CI -0.35 to 0.10 (45 W/min). Intraclass correlation coefficients for the VO2 at the [HHb]BP vs the RCP were 0.94 (15 W/min), 0.98 (30 W/min), and 0.93 (45 W/min).

CONCLUSION: The results of this study demonstrate that the VO2 at which the [HHb]BP and the RCP occur is unaffected by variations in the slope of ramp-incremental cycling exercise. Additionally, the fact that the VO2 at the [HHb]BP and RCP were not different between tests, were highly correlated, and had no significant bias provides further evidence of their shared physiological basis.

ENDOTHELIAL FUNCTION AFFECTS MUSCLE PROTEIN ANABOLIC RESPONSE IN HEALTHY AND DIABETIC OLDER ADULTS AFTER 12 WEEKS OF RESISTANCE EXERCISE TRAINING

MORO, T., RANDOLPH, A., PAOLI, A., RASMUSSEN, B., VOLPI, E.

UNIVERSITY OF PADOVA

INTRODUCTION: Aging is characterized by a slow and physiological decline in muscle quality and function. Resistance exercise (RET) is known to restore muscle quality in healthy older adults; however, Type 2 diabetes (T2DM), which is associated with an altered muscle protein metabolism and vascular functions, may reduce the anabolic effect of exercise. The aim of this study was to indagate the effectiveness of RET in a group of healthy and diabetic older adults.

METHODS: 15 healthy older adults (68.3±4.3 years) and 15 diabetic older adults (71.1±4.7 years) underwent to 12 weeks of RET. Muscle strength, body composition analysis and muscle biopsies from vastus lateralis were obtained before and after 12 weeks of training. Muscle protein synthesis (MPS) was assessed during a stable isotope infusion experiment wherein subjects ingested an essential amino acid (EAA) mixture to test their anabolic response. Cross-sectional area (CSA), satellite cell abundance (SC) and capillary content were measured immunohistochemically.

RESULTS: Both T2DM and healthy older adults increased appendicular muscle mass and strength after training. Basal MPS was significantly different between groups before the intervention ($p=0.048$) and increased in both group with training; whereas, contrary to the healthy group, T2DM didn't show any anabolic response to EAA before or after the RET intervention, which seems to be explained by a decreased in the amino acid transport. Moreover, only healthy older adults increased total fiber CSA ($p<0.05$), with a specific increase in fiber type II size (+23%; $p<0.05$). Healthy older adults also presented a higher capillary and SC content compared to the T2DM pairs ($p<0.05$), but training did not affect these parameters.

CONCLUSION: T2DM seems to be characterized by an anabolic resistance and this may be due to an endothelial dysfunction. Unfortunately, 12 weeks of RET seems only to partially ameliorates the discrepancy.

COMBINED EFFECTS OF MECHANICAL STRESS AND NUTRITION ON MUSCLE HYPERTROPHIC SIGNALS BY USING CONTRACTILE 3D-ENGINEERED MUSCLE

YI, D., SUGIMOTO, T., HASHIMOTO, T.

RITSUMEIKAN UNIVERSITY

INTRODUCTION: Given that muscle cross-sectional area and muscle strength are correlated, increases in muscle mass constitute key components of conditioning in various sports. To effectively induce muscle hypertrophy, mechanical stress (e.g., resistance exercise) and nutritional support may be attractive strategies. Indeed, our recent research showed that maca can induce muscle hypertrophy in C2C12 skeletal muscle cells [1]. However, a combined effect of maca and mechanical stress has not been investigated.

Usually, electrical pulse stimulation (EPS) can lead to mechanical muscle contraction and mimic the overall intracellular signal activation to exercise in skeletal muscle cell culture, albeit these cells are structurally different from in vivo skeletal muscle tissue [2]. On the other hand, three-dimensional (3D)-engineered muscle (3D-EM) is structurally composed of highly dense, parallel-orientated fascicle-like structures of myofibers, forming sarcomere structures like those found in living muscle. Thus, a 3D-EM may more closely represent in vivo muscles [3].

Thus, in this study, we aimed to investigate the effect of combining exercise (EPS) and nutrition treatment (maca) on muscle hypertrophic cell signaling in 3D-EM.

METHODS: 3D-EM were cultured as in the previous study [3]. After 2 weeks of differentiation, all the 3D-EM were divided into 3 groups: control (C) group (n=3), EPS (E) group (n=6), and maca + EPS (ME) group (n=6). The C group and E group were incubated normally, and the ME group was treated with 1mg/ml of maca. The medium was changed every 2 days, for one week. After changing the medium each time, we applied 30V, 1Hz, and 2 msec EPS to 3D-EM for 24h, and then rested for 24h. The EPS also continued for a week. 24h after the last time of EPS, intracellular signals of muscle protein were analyzed by Western blotting.

RESULTS: In the ME group, the phosphorylation of ERK tended to be prompted compared with the C group ($p=0.06$), and the phosphorylation of mTOR also tended to be higher than that in the C group ($p=0.09$). Furthermore, the treatment of maca and EPS promoted the phosphorylation of AMPK compared with the C group ($p<0.05$). On the other hand, the expression of MAFbx and MuRF-1 were not significantly different.

CONCLUSION: Since the treatment of maca and EPS tended to promote a part of the signals of MPS without significant differences in the signals of MPB except for the increase in the AMPK phosphorylation, it is considered that the combination of maca and mechanical stress may have a potential to promote muscle hypertrophic process. However, more samples are needed in further studies for a robust conclusion. Nonetheless, given that few prior studies investigated the effects of EPS and nutritional treatment on this mold of 3D-EM, our preliminary study might provide important findings to explore effective prescriptions for muscle hypertrophy.

A COMPARISON OF FULLTRACK AI APP AS AN ALTERNATIVE TO RADAR GUN MEASURED CRICKET BALL DELIVERY SPEED

SHORTER, K.1,2, TISSERA, K.3, HUYNH, M.4, BENSON, A.C.3

1. UNIVERSITY OF SOUTH AUSTRALIA 2. UNIVERSITY OF NEW ENGLAND 3. SWINBURNE UNIVERSITY OF TECHNOLOGY 4. LA TROBE UNIVERSITY

INTRODUCTION: Ball delivery speed is a key performance indicator in cricket. Whilst 3D motion capture is accepted as the gold standard in movement analysis [1], radar guns are commonly used in cricket training due to their immediacy in providing ball speed, accessibility and portability but are often cost inhibitive. In contrast, the development of app-based approaches have become feasible alternatives, providing both ball trajectory visualisation and expanded metric reporting, including speed. This study investigated the practical agreement between a validated radar gun [2] and a new app-based approach to measure ball speed under cricket training conditions.

METHODS: 467 deliveries were recorded, via radar gun (Stalker ATS2) and app (Fulltrack AI), on an indoor cricket wicket (bowled or thrown (Sidearm Pro)). Of these, 163 deliveries were captured at the higher level of acceptable setup tolerance for the radar gun (offset 20 degrees relative to wicket) [1] and both raw and corrected (via applying the cosine law [3]), data (km/hr) were analysed. Fulltrack AI data were recorded from an iOS device positioned behind the stumps following the app-calibration procedure. Ball speed (km/hr) from Fulltrack AI was extracted post-session into Microsoft Excel for tabulation with radar gun data. Statistical analyses were conducted in R Statistical Software [4]. Differences between methods (radar gun vs app) were assessed via a linear mixed model after normality assessment and removal of extreme outliers (bestNormalize package [5]). Agreement, 95% limits of agreement (LOA) were calculated using Bland-Altman [6]. Reliability was further assessed with intraclass correlation coefficient (ICC).

RESULTS: Statistically significant mean differences ($p<0.001$) in ball speed were identified between the radar gun and app. When setup behind the wicket, the radar gun measured speeds 0.51 km/hr lower (95% CI: -0.98, -0.03), compared to the app. At 20 degrees offset from the wicket, the radar gun reported speeds 4.08 km/hr slower (95%CI: -4.41, -3.74), or 1.01 km/hr faster (95%CI: 0.67, 1.35) when corrected via the cosine law. Whilst LOA established fair agreement (<2SD) and reliability coefficients indicated near perfect agreement (ICC=0.94) when behind the wicket, LOA decreased (poor-to-fair; 2-3SD, [6]) when the radar gun was offset by 20 degrees, whilst ICC remained near perfect (ICC>0.95).

CONCLUSION: The Stalker ATS2 radar gun and Fulltrack AI app demonstrated sound practical agreement in monitoring ball delivery speed for cricket bowlers. For the practitioner, whilst the app is a viable field-based approach instead of using the radar gun, the statistically significant differences in speed suggest caution should be taken if using the two devices inter-changeably to directly compare ball speed to monitor a bowler's performance.

NEW TECHNOLOGICAL ADVANCES TO PROTECT PEOPLE WHO EXERCISE IN VARIOUS THERMAL ENVIRONMENTS

IOANNOU, L.G.1, CIUHA, U.1, FISHER, J.T.1, TSOUTSOUBI, L.1, TOBITA, K.2, BONELL, A.3, COTTER, J.D.4, KENNY, G.P.5, FLOURIS, A.D.6, MEKJAVIC, I.B.1

1 JOZEF STEFAN INSTITUTE, 2 OSAKA METROPOLITAN UNIVERSITY, 3 LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE, 4 UNIVERSITY OF OTAGO, 5 UNIVERSITY OF OTTAWA, 6 UNIVERSITY OF THESSALY

INTRODUCTION: Adverse thermal conditions, such as the ones often experienced by people who exercise in the heat, together with the increased metabolic demands that frequently accompany an exercise session, often exceed the human capacity for thermoregulation. This, in turn, reduces physical performance and increases the overall risk for life-threatening diseases and accidents. Despite the importance of proactivity, which is undeniable and plays a key role in many fields of our daily routine, there is currently no easy way for sport scientists, exercise physiologists, and coaches to provide state-of-the-art guidance to people who exercise in unsuitable thermal and exercise conditions. Therefore, the aim of this study was to develop an intelligent mobile phone application that will allow sport scientists, exercise physiologists, and coaches to provide individualized heat-health guidance to people who exercise and/or compete in unsuitable environmental conditions.

METHODS: We used concurrent technological advances and thermophysiological modelling to develop a mobile phone application that predicts the physiological heat strain experienced by people who perform in various conditions and provide them with personalized heat mitigation strategies (e.g., clothing, exercise intensity, exercise/rest cycles, and water consumption suggestions) that will help them to preserve physical performance and reduce physiological heat strain. To examine the construct validity of the newly-developed mobile phone application, the present study involved monitoring 37 healthy participants [gender: 29 (M) and 8 (F); body mass: 77.1 ± 14.8 kg; height: 175.2 ± 9.0 cm; age: 28.9 ± 5.7 years) during various physical activities (duration: 104 to 180 mins; metabolic rate: 106.1 to 601.8 W/m2] that took place in various environmental conditions (Wet-Bulb Globe Temperature: −11.5 to 26.9 °C). Core body temperature measurements were continuously recorded using ingestible telemetric capsules to examine the predicting capacity of our mobile application in preclassifying individuals with increased risk for experiencing elevated physiological heat strain, based on the guidelines (≥ 38 °C) of the World Health Organization.

RESULTS: The core body temperature predictions made by the newly-developed mobile phone application were strongly related ($r = 0.66$, $p < 0.05$) with the actual physiological measurements taken by our participants, and, more importantly, our mobile application was able to correctly predict 92% of the people who experienced increased physiological heat strain.

CONCLUSION: Mobile phone applications integrating thermophysiological models may be used in the future as a means to provide individualized heat-health guidance to safeguard the health and physical performance of those who often experience increased physiological heat strain.

DESIGN OF A SOFTWARE SUITE TO SUPPORT INDEXING, ANNOTATING, AND ANALYZING CLIMBING VIDEOS

LEROY, P.1, FRUCHARD, B.1, GOYALLON, T.1, DUPRAT, G.2, AVEZOU, C.2, DEWILDE, P.2, REVERET, L.1

INRIA 1, FFME 2

INTRODUCTION: Capturing high-resolution videos is now accessible to coaches and athletes during training sessions and competitions. This leads to accumulating hours of footage without means to store and retrieve this content easily when studying specific athlete performances. Commercial solutions exist but may imply significant fees. We designed and built a software pipeline in collaboration with the French Federation for Climbing (FFME) to efficiently index and annotate performance videos that supports analysts and coaches when analyzing videos.

Keywords: Video indexation, video annotation, analytical tools

METHODS: To build this application, videos of individual athlete performances captured during official competition by the coaches have been indexed following results made available on-line by the International Sports Climbing Federation (IFSC). Videos from training sessions have been also included using a dedicated indexing. We built a web application (Dash Plotly [1]) allowing the FFME members to navigate through the database, and designed an annotation tool to support analysis [2] that enables categorizing events in a performance (similar to [3, 4]) and visualizing quantitative data (e.g., average grasping time). All data and software are secured on a server respecting the European General Data Protection Regulation (GDPR).

RESULTS: Analysts and coaches used the tools to upload 923 videos that represent 72 GB of data and 43.7 hours of video. They annotated 498 videos with an average of 156 [150,162] (95% confidence intervals) annotations per videos. The annotation sessions lasted in average 30.3 min [28.6, 32.1]. This collaborative work fostered discussions on the need to use analytical tools, and revealed the lack of technological support international teams might face.

CONCLUSION: Sport teams might be missing conventional measures of performance and tools to support analyzing large quantities of videos. A dedicated software pipeline enabled them to capitalize on the video content they accumulated. We are currently completing this pipeline with an interactive tool to support exploring annotation data. Despite we collaborated with climbing experts, we expect such a software pipeline to easily transfer to other sport disciplines with similar needs. We started working with the French boxing federation to ascertain this claim.

GAME-DESIGN FOR A HIGH-INTENSITY EXERGAME: TRAINING VOLUME AND FITNESS IMPROVEMENT WHILE PLAYING TO PROMOTE PHYSICAL ACTIVITY

AUDET, A., ST-MARTIN-DEROUIN, D., PARENT, A.A.

UNIVERSITÉ DU QUÉBEC À RIMOUSKI

INTRODUCTION: Active video games to promote physical activity are not recommended by health guidelines. Thus, the studys goal was to assess the ability of new gameplay to encourage physical activity and provide beneficial physical fitness changes.

METHODS: A total of 19 inactive (9 women and ten men) completed the study. Pre- and post-training measurements included 1) body composition, 2) aerobic capacity, 3) muscle endurance, and 4) flexibility. The participants engaged in 45-60 min per week for five weeks, ten sessions playing an active video game where the volume was measured with a heart rate monitor. During the intensity validation of the game, the oxygen uptake (VO2) and energy expenditure (EE) was measured with a portable metabolic analyser (K4b2, Cosmed, It.)

RESULTS: The average METs during the games were 4±1 to 7±1 METs, and the % VO2max extrapolated in an average of games was between 44±6 and 85± 10 %, with some peaks at maximal effort. The range average training volume during the intervention was 288-480 METs min/week. Significant improvements were seen in all three components before vs after the intervention: 1) a decrease in percent body fat (28±7 vs 26±8%, $p<0.05$) and from waist circumference (83±10 vs 77±14 cm, $p=0.01$), 2) the aerobic capacity increased (34±5 vs 38±6 ml/kg/min, $p<0.01$); 3) upper (push-ups) and lower (squats) muscle endurance increased (24±12 vs 43±12, $p<0.01$), and (46±8 vs 65±9, $p<0.01$) respectively; and 4) flexibility increased (21±11 vs 26±11, $p<0.05$).

CONCLUSION: In conclusion, it appears that 45-60 min per week for five weeks of medium to high-intensity exercise with this gameplay was sufficient to induce significant changes in body composition, aerobic capacity, and muscle endurance in inactive individuals, even if the volume training was lower than the ACSMs recommendations of more than 500-1000 METs min/week. These results emphasize the potential health benefits of using this tool to promote physical activity and increase activity gradually for the inactive population. However, further investigation will need to be done to observe the adherence of this game in an ecological environment.

LIGHT REFLECTION-BASED SYSTEM FOR SPIN MEASUREMENT OF TABLE TENNIS BALLS

DELUMEAU, T.

NANTES UNIVERSITÉ

INTRODUCTION: Mastering spin is crucial to win a match in table tennis. Spin is one of the keys performance indicators for a player, alongside with placement, ball speed, technique and precision. Therefore, it is crucial to measure performance.

However, spin measurement is hard to perform in real match conditions because the speed is high (+/-800 rad/s)[1], unless using a high-speed cameras and using image processing algorithms.[2]–[5]

We proposed a new low-cost tool for spin measurement based on observation of light reflection on balls. The proposed system is also able to measure linear speed from a moving object in its field of view (FOV).

METHODS: To calibrate accurately our system, comparisons are made with a high-speed camera Miro C210 from Phantom.

First experiment is the measure in controlled conditions. The system is used to measure a spinning ball mounted on a motor with constant speed (to ensure the measurement quality of the device).

Second experiment is the observation of the spin on real strokes. Strokes were performed by an experienced senior player. Services and hits were realized several times with increasing spin given by the player. Balls were delivered by a ball thrower robot (Amicus Expert from Butterfly).

Spin estimation with camera is obtained through frame by frame analysis, while our system is expressing spin by frequency and waveform analysis.

RESULTS: Experiment 1 shows a measured spin at 468,7 rad/s (+/-18,8 rad/s).

Experiment 2 shows various spin measures, for strokes and services. Services observed spin range goes from 174 rad/s to 329.23 rad/s.

Strokes performed for topspin forehand shots range goes from 391.75 rad/s to 808.6 rad/s.

Strokes performed for topspin backhand shots range goes from 569.8 rad/s to 769 rad/s. Linear speed measured on forehand & backhand shots is really close from the one measured by camera (+/3.46%).Estimated error between High speed camera and our system is +/-5.6%.

CONCLUSION: Although results are consistent with high-speed camera, we observe that the system is light-sensitive. It would not be able to detect in a fully lightened or a fully dark environment or at least with a larger error.

We are using bicolored balls which won't be allowed in real match conditions. Traditional match balls, with their natural brands are not reflective enough to get a meaningful output.

Nonetheless, the presented system, shows strong results in accordance with a high-speed camera for both measuring linear and rotational speed.

REPEATABILITY AND REPRODUCIBILITY OF AN ON-FIELD DEVICE FOR MEASURING LOW- TO HIGH-FREQUENCY MUSCLE FORCE RATIO.

BERNARD, O.

FACULTÉ DES SCIENCES DU SPORT

INTRODUCTION: Low-Frequency Fatigue (LFF) refers to a long-lasting impairment of muscle contractility, induced by a fatiguing physical task. Its gold standard assessment, commonly restricted to laboratory studies, is based on the low- to high-frequency force ratio produced by an electrically stimulated muscle (L/HFratio); the higher the exercise-induced depression of L/HFratio, the higher the LFF. A recent study has tested a portable device (MYOCENE, Liège, Belgium) as a measurement tool of L/HFratio (called Powerdex value, expressed in percentage) in the field [1], allowing the quadriceps LFF monitoring of sport practitioners. The aim of the present study is to evaluate the repeatability and reproducibility of Powerdex measurements, under field conditions.

METHODS: 16 healthy students volunteered for an initial familiarization session with MYOCENE measurements. Then, two experimental sessions (over two weeks) aimed to study 1) the repeatability of two consecutive Powerdex measurements (seven minutes apart), and 2) the effect of time of day (8:00 a.m., 12:00 p.m. and 5:00 p.m.) on the reproducibility of Powerdex measurements. For all sessions, participants were asked to refrain from moderate to intense physical activity, the measurements were performed by the same operator, with the same device, and the position of the skin muscle electrical stimulation electrodes was exactly the same throughout each session. For each session, the agreement between the pairs of within-subjects measurements was assessed by a Bland & Altman plot [2]: the bias was estimated as the mean of the paired differences, the repeatability coefficient was estimated at 1.96 x standard deviation of paired differences, and upper and lower limits of agreement were calculated as the bias ± 1.96 x standard deviation of paired differences.

RESULTS: The analysis of repeatability shows an anecdotal bias (-1,6%) between the second and the first Powerdex measurement, probably due to a small fatigue effect caused by electrical muscle stimulation. The repeatability coefficient is 2,97 %. The largest bias between the Powerdex values measured at different times of the day (reproducibility analysis) is 1,2 %, the largest upper limit of agreement is 10,9 % and the largest lower one is -11,4 %.

CONCLUSION: The repeatability of the paired Powerdex measurements suggests that an exercise-induced Powerdex depression of at least 3 % is required to conclude to the onset of Low-Frequency Fatigue. Further studies are required to assess more accurately the reproducibility of the device, as the daily activities may have modified the muscular contractility, either by a slight potentiation or a small fatiguing effect.

IS MARKERLESS MOTION TRACKING A FEASIBLE APPROACH FOR IN FIELD KINEMATIC ANALYSIS OF WEIGHTLIFTING?

HOLZER, D., HUMMEL, C., PATERNOSTER, F.K., STÖCKER, F., THIELE, F.

TECHNICAL UNIVERSITY MUNICH

INTRODUCTION: In weightlifting, a quantitative kinematic analysis of an athlete can be useful to assess the performance during the snatch. A marker-based approach (MB) is widely used to obtain kinematic data in weightlifting [1]. Yet, it is not suitable for in field activities such as competitions. Recently developed markerless video-based systems (VB) working with deep learning-based pose estimation algorithms might be an alternative approach [2]. However, the applicability and accuracy of VB systems in assessing highly dynamic full body activities remain mostly unexplored. Hence, the aim of this study was to compare the kinematics of a snatch using a VB along with a MB approach.

METHODS: 24 experienced weightlifters (17 Male, 7 Female) each performed 6-9 snatches with a load between 65-85% of their individual one repetition maximum. MB (200Hz using Vicon Nexus) and VB (100Hz using Contemplas with Theia3D for pose estimation) 3D motion capture were used to analyze snatch kinematics of 140 trials. The results of the VB tracking

system were compared to the MB system to validate the technology regarding the accuracy during the snatch. Statistical parametric mapping (SPM) and paired t-tests were used to demonstrate differences between the two systems.

RESULTS: Preliminary results of 4 subjects (29 trials) showed that on average joint center estimation between the systems differed by 30±9mm for the knees, 27±9mm for the ankles, 49±10mm for the hip and 48±9mm for the shoulder joints. This resulted in significant differences ($p < 0.05$) regarding joint angle estimations (e.g. maximal flexion, maximal angular velocity, and average velocity). Average differences were 5±2° for the knee, 18±5° for the hip and 8±4° for the ankle joint. SPM analysis revealed significant differences throughout the majority of all phases of the snatch. For example, the transition phase between first and second pull was far less pronounced or barely detectable by the VB system.

CONCLUSION: In preliminary results, we found significant differences in all variables analyzed. Joint center location was similar to previous studies [3].The major difference found was the far less pronounced transition phase in the VB tracking results, which is a key phase to analyze during the snatch. Besides that, overall shape of lower limb kinematics was similar. However, shoulder kinematics were barely comparable with maximal shoulder abduction angles highly underestimated by the VB system (25%). Further, big differences regarding maximum angular velocities indicate difficulties in the comparability between the two systems. As a result, our preliminary results suggest that accuracy of VB motion capture is not yet sufficient for high quality kinematic analysis of weightlifting. However, given the practicality, it should be a promising alternative to analyze weightlifting performance in the future.

IMPROVEMENT IN PERIPHERAL VISUAL ATTENTIONAL PERFORMANCE IN PROFESSIONAL SOCCER PLAYERS FOLLOWING A SINGLE NEUROFEEDBACK TRAINING SESSION

ASSADOURIAN, S., BRANCO LOPES, A., SAJ, A.

UNIVERSITY OF MONTREAL

INTRODUCTION: The effectiveness of EEG-neurofeedback (EEG-NFB) in modulating cognition has been the subject of much research for several years, particularly concerning attentional functions in healthy subjects and those with attentional deficits. However, its effectiveness on sports performance remains poorly studied, and its use is not widely practised among athletes, notably because of its questionable accessibility and effectiveness. This study aims to show that this technology can be accessible and that Alpha EEG-NFB is immediately effective. Fifteen professional soccer players took part in this study.

METHODS: Using a novel EEG headset installed in less than one minute and new processing software, the players performed three sessions of two different peripheral attentional tasks: immediately before, immediately after and one month after a single Alpha EEG-NFB training session.

RESULTS: The results showed a significant effect on both tasks immediately after EEG-NFB training, with an immediate performance increase of more than 30% that remained at 20% one month later.

CONCLUSION: This study, the first to use this headset and software, shows that improvement in sports performance can be related to cognitive performance, especially peripheral visual attentional functions. Furthermore, it demonstrates that the EEG-NFB is accessible and effective for high-level athletes. This simple paradigm could supplement existing rehabilitation approaches depending on the individual's needs and abilities to alleviate persistent spatial attention deficits.

AI-DRIVEN SPRINT KINEMATICS ANALYSIS USING SAGITTAL VIDEO FOOTAGE FOR HIGH-PERFORMANCE SPRINTING

GALIZZI, V.

CEA

INTRODUCTION: Sprint kinematics can be a key factor to prevent injuries during running, but obtaining accurate measures using motion capture devices is costly, impractical and time consuming. We present an AI driven method for sprint performance analysis. The proposed approach utilizes RGB cameras placed in the sagittal plane to capture video footage of the sport activity. A deep learning model (1) is then used to locate human body joints on the image for each frame. The cameras are positioned such that main joint angles and kinematics can then be precisely computed throughout the sprint.

Although the presented method can be used as a tool for general sport analysis, it is extensively studied here in the context of high performance sprinting. Validity of such 2D measures from videos is a subject of high interest that remains badly explored (2).

METHODS: Six different athletes performed six sprints of different lengths with various force loads. The five first and five last meters of each run were recorded using two RGB cameras placed along the track in the sagittal plane. An optical measurement system is also employed to record precise foot contact events.

Video footage are then processed and obtained contact events are compared with the

measurements.

From the video stream, the athlete is detected with a neural network YOLOX. From an extracted thumbnail around the athlete, pose estimation is computed with (1). From analysis of bottom limb joint trajectories, ground contact instants are pointed out. Finally, from a weak calibration between the track coordinate system and the image one, 3D positions are estimated at each ground contact instant.

RESULTS: Pose estimation with AI methods depends on the learning databases. However, these only give the position of the knee and ankle for the lower limbs. The parameters of flight time, contact time and stride length are therefore deduced from the kinematic derivatives of these points and will be qualified with respect to the gold-standard of the optical system on the ground. The evolution of the measurement bias over time is also a parameter that will be evaluated.

CONCLUSION: From our preliminary results, we note that the characterization of the time of contact onset and contact termination is more difficult to determine precisely than the length of the stride, which is relatively stable given that the feet on the ground are fixed during contact. A more complete model including tip of the foot localization would most certainly lead to more precise kinematics. Nevertheless, the simplicity of the method and its ease of use make it an efficient and valuable tool for computing kinematics and gaining insights about the sprint performance.

MANIPULATION OF ROS DURING ACUTE EXERCISE AND SPRINT INTERVAL TRAINING USING POST-EXERCISE ISCHAEMIA-REPERFUSION DEMONSTRATES A DIFFERENTIAL REGULATION OF NOX ISOFORMS IN HUMAN SKELETAL MUSCLE.

PEÑA-VEGA, P.1, GARCIA-GONZALEZ, E.1, MARTINEZ-CANTON, M.1, GALLEGO-SELLES, A.1, GALVAN-ALVAREZ, V.1, GARCIA-PEREZ, G.1, SANTANA, A.2, FERNANDEZ-GARCÍA, B.3, BOUSHEL, R.4, HALLEN, J.5

CALBET, J.A.L.1,5, MARTIN, R.1

INTRODUCTION: The main function of isoforms 2 and 4 of NADPH Oxidase (NOX) in human skeletal muscle (hSM) is the production of free radicals. NOX2 resides in the sarcolemma and t-tubules and generates ROS during contractile activity. NOX4 is a monomeric enzyme located in the SR and mitochondria and associated with basal ROS production in SM. Superoxide produced by these enzymes regulates ryanodine receptor opening and Ca2+ release from SR. The present investigation aimed to determine the plasticity of NOX2 and NOX4 with acute intense exercise (IE) and sprint interval training (SIT), with usual or exacerbated ROS production by using severe hypoxia and post-exercise ischaemia. We hypothesised that NOX2 would be the isoform primarily upregulated by acute exercise and training and that the magnitude of the changes would depend on the level of ROS incurred.

METHODS: In study 1, 11 active males performed IE in Normoxia (Nx) and Hypoxia (Hyp) (PIO2:73 mmHg). Immediately after IE, the circulation of one leg was instantaneously occluded (300mmHg). Biopsies from VL were taken before (PRE1), 10 (POST, solely occluded leg) and 60s after exercise from the occluded (OC1M) and non-occluded (nOC1M) legs. In study2, 10 active subjects were tested before and after SIT (4-6 30s sprints with 4 min recovery periods, 6 sessions in 2 weeks). Immediately after each 30s sprint, the circulation of one leg was occluded for 30-50s. VL biopsies were obtained at rest before (PRE2) and after training bilaterally from the leg training with free circulation (FCL) and the leg training with post-exercise ischaemia (IS). Protein expression was measured (WB). Statistics: t-student and repeated-measures ANOVA.

RESULTS: Study1: compared to PRE, phospho-p47phox subunit of NOX2 was increased 4 and 10-fold at POST and OC1M, respectively ($p<0.001$) and similarly in Nx and Hyp (time effect $p<0.001$). phospho-p47phox subunit of NOX2 was maintained elevated in nOC1M ($p= 0.008$). No significant changes were seen for NOX4 (time effect $p=0.10$), although there was a reduction in NOX4 (18%) from PRE to OC1M when both conditions were analysed conjointly (time effect $p=0.026$). Study2: phospho-p47phox subunit of NOX2 was increased 4.3-fold and 3.0-fold in IS and FCL, respectively (time effect $P=0.002$, time*ischaemia $P=0.29$). gp91 subunit of NOX2 was increased 1.6-fold and 1.4-fold in IS and FCL, respectively (time effect $P=0.004$, time*ischaemia $P=0.28$). It did not alter NOX4 expression in either IS or FCL (time effect $p=0.68$).

CONCLUSION: This investigation shows that IE and SIT upregulate the skeletal muscle expression of NOX2 subunits but not NOX4 in humans. Manipulating ROS by including severe hypoxia or brief post-exercise ischaemia during SIT did not further upregulate NOX2. It remains to be determined why upregulation of NOX2 is required in response to acute high-intensity exercise and SIT.

EXERCISING TO EXHAUSTION IN NORMOXIA AND SEVERE ACUTE HYPOXIA ACTIVATES STAT SIGNALLING IN HUMAN SKELETAL MUSCLE: POTENTIAL MECHANISMS.

GARCIA-PEREZ, G.1, GALLEGO-SELLES, A.1, GALVAN-ALVAREZ, V.1, MARTINEZ-CANTON, M.1, GARCIA-GONZALEZ, E.1, PEÑA-VEGA, P.1, SANTANA, A.2, DORADO-GARCIA, C.1, CALBET, J.A.L.1,3, MARTIN-RINCON, M,1

1 IUIBS AND ULPGC, SPAIN; 2 CLIN. GENETICS UNIT CHUIMI, LPA, SPAIN; 3 DEP. PHYSICAL PERFORMANCE, NIH, NORWAY.

INTRODUCTION: The Signal Transducer and Activator of Transcription (STAT) signalling pathway plays a crucial role in the regulation of cell differentiation, proliferation, and apoptosis. STAT3 and STAT5 are stimulated by extra and intracellular signals such as interleukins and RONS and are involved in the regulation of metabolism and antioxidant response. Conflicting results have been reported in human skeletal muscle (HSM) on whether STAT signalling is upregulated by acute exercise and on how exercise intensity, type and concomitant redox perturbations may influence STAT signalling. However, studies have yet to elucidate the mechanisms that could explain such differences in STAT activation. The present investigation aimed to determine whether the STAT signalling is activated by incremental exercise to exhaustion and to elucidate the role in this process of IL-6 and FGF-21, oxygenation and metabolite accumulation. We hypothesized that exercise eliciting high levels of RONS, such as hypoxia and a large metabolite accumulation, are required for STAT activation in HSM.

METHODS: Eleven physically active men performed IE in Normoxia (Nx) and Hypoxia (Hyp) (PIO2:73 mmHg). Immediately after IE, the circulation of one leg was instantaneously occluded (300 mmHg). Protein expression (WB) and muscle metabolites were measured in m. vastus lateralis biopsies before (PRE), 10 (POST, solely occluded leg) and 60s after exercise from the occluded (OC1M) and non-occluded (nOC1M) legs. Blood was sampled from the femoral vein. Statistics: repeated-measures ANOVA.

RESULTS: Compared to PRE, pSTAT3-Tyr705, pSTAT5-Tyr694 and pSTAT5-Tyr694+pTyr705-STAT3 and FGF21 were increased at POST and OC1M ($p<0.001$), similarly in Nx and Hyp. Compared to PRE, SOCS3 was 16% and 22% lower at POST and OC1M ($p=0.008$) regardless of PiO2. Consequently, the ratio pTyr705-STAT3/Total STAT3 was increased 4.9 and 4.1-fold at POST and OC1M, respectively ($p=0.005$), regardless of PiO2. pSTAT3-Tyr705, the ratio pTyr705-STAT3/Total pSTAT5-Tyr694, pSTAT5-Tyr694 + pTyr705-STAT3, FGF-21, and SOCS3 returned to pre-exercise values at nOC1M ($p>0.05$ vs PRE). IL-6 expression (25kda+45kda isoforms) was 22% lower after exercise compared to the average of both PRE.

CONCLUSION: In summary, this study demonstrates a fast activation of STAT3 and STAT5 signalling with exercise to exhaustion in HSM, which is driven by the level of oxygenation and the accumulation of metabolites, but independent of FiO2. The activation of the JNK/STAT3 signalling pathway may be mediated by FGF-21, which has been shown to reduce inflammation and oxidative stress after exercise in skeletal muscle. Furthermore, STAT3 phosphorylation may occur despite a reduction in muscle IL-6. Therefore, the fast kinetics of these signals after exercise should be considered when analysing and interpreting muscle signalling responses to exercise.

Grants: DEP2017-86409-C2-1-P; PID2021-125354OB-C21, Swedish Olympic Committee (070–4058960), CSD (EXP_75119), Cabildo Gran Canaria (12/22) and FDCAN.

THE ABILITY OF AN INFRARED RADIATION EMITTING FABRIC TO ACTIVATE ENOS AND CAMKII IN C2C12 CELLS

BOND, J.1, MARTIN, N.R.W.1, BAILEY, S.J.1, BROWNSTONE, T.2, FERGUSON, R.A.1

1 LOUGHBOROUGH UNIVERSITY, LOUGHBOROUGH, UK; 2 KYMIRA LTD, READING, UK

INTRODUCTION: Angiogenesis, the formation of new capillaries, and mitochondrial biogenesis, the synthesis of mitochondria, are two adaptive responses to exercise training. Pertinent to these adaptive responses are activation of the endothelial nitric oxide synthase (eNOS) (1) and upstream signalling proteins such as Ca2+/Calmodulin (CaM)-dependant kinase II (CaMKII) (2). Infrared radiation (IR) emitting lamps have been shown to activate eNOS, increasing nitric oxide (NO) production, and CaMKII (3) in vitro. KYMIRA garments powered by Celliant are a novel IR emitting technology that re-emit absorbed body heat as IR. Whether activation of eNOS and CaMKII is apparent when an IR emitting fabric is the source of IR is unknown. We hypothesised that KYMIRA IR emitting fabric would activate adaptive pathways in cultured C2C12 cells.

METHODS: Differentiated C2C12 cells were exposed to either a KYMIRA powered by Celliant IR emitting fabric (IR) or no fabric (CON) for 0, 5, 15, 30, 60 or 90 minutes (n=6) or for 0, 2, 4, 8, 24 or 48 hours (n=12), in two separate experiments. Each timepoint had time-matched IR and CON cells. Cell lysate was frozen for subsequent analysis of total and phosphorylated eNOS and CaMKII by Western blot. Total protein expression was normalised to a Ponceau S stain and phosphorylated protein to total protein expression, with data presented as a fold change. Data were analysed using a two-way (condition x time) ANOVA with Bonferroni post-hoc analysis where a significant main effect or a significant interaction was present. Statistical significance was accepted at $p < 0.05$. Data are presented as mean ± SD.

RESULTS: There was no change to eNOS phosphorylation, with total eNOS expression reduced at 24 hours in IR vs CON (1.8 ± 0.8 vs 2.6 ± 0.8 fold; $p=0.008$). There was greater CaMKII phosphorylation with IR exposure compared to CON after 5 minutes (8.9 ± 3.2 vs 5.3 ± 0.8 fold; $p=0.030$) with IR being less phosphorylated compared to CON after 48 hours (2.4 ± 1.2 vs 5.6 ± 1.9 fold; $p=0.005$). Total CaMKII expression was reduced after 48 hours in IR vs CON (13.7 ± 2.6 vs 15.8 ± 2.8 fold; $p=0.012$).

CONCLUSION: These results suggest that IR exposure increased CaMKII activity in C2C12 cells after 5 minutes and reduced such activation after 48 hours. eNOS activity appears not to have been changed, a finding that was unexpected but

that may be due to the type of cell used. An explanation for the CaMKII result is not clear, however one possibility is CaMKII was S-nitrosylated.

ZYNAMITE PX SUPPLEMENTATION MODULATES SKELETAL MUSCLE SIGNALLING ELICITED BY EXERCISE AND POST-EXERCISE ISCHAEMIA-REPERFUSION IN HUMANS.

MARTINEZ-CANTON, M.1, GALVAN, V.1, GARCIA-GONZALEZ, E.1, GALLEGO, A.1, GELABERT, M.1, GARCIA-PEREZ, G.1, PEÑA-VEGA, P.1, SANTANA, A.1,2, MARTIN, M.1, CALBET, J.A.1,3,4

1ULPGC AND IUIBS, SPAIN; 2CLINICAL GENETICS UNIT. MATERNAL AND CHILD INSULAR UNIVERSITY HOSPITAL COMPLEX, LAS PALMAS, SPAIN; 3THE UNIVERSITY OF BRITISH COLUMBIA, VANCOUVER, CANADA; 4NIH, OSLO, NORWAY

INTRODUCTION: Zynamite PX (Zyt) is a natural polyphenol mixture rich in mangiferin combined with quercetin. Zyt is a potent antioxidant due to the iron-chelating effect of mangiferin and the inhibitory action of mangiferin and quercetin on the ROS-producing enzymes xanthine oxidase (XO) and NADPH oxidase (NOX). XO and NOX generate ROS during high-intensity exercise and ischaemia-reperfusion. Zyt enhances performance during repeated sprint exercise and attenuates post-exercise muscle damage. Experiments in cells and rodents indicate that mangiferin and quercetin may upregulate nuclear factor erythroid-derived 2-like 2 (Nrf2), a master switch of the antioxidant response. However, it remains unknown whether Zyt increases basal and exercise-induced Nrf2 signaling. Therefore, we hypothesized that Zyt would enhance basal antioxidant capacity resulting in a blunted ROS-mediated signaling response to exercise and ischaemia-reperfusion in human skeletal muscle.

METHODS: Twenty-six volunteers were assigned to a control (17 males) or supplementation group (8 males), the latter supplemented with Zyt (140 mg of MLE + 140 mg quercetin) every 8h for two days. The next day subjects reported to the laboratory fasted, and received the last dose of Zyt, followed one hour later by an incremental exercise to exhaustion (IE) and unilateral leg occlusion for 60s. Upon cuff release, subjects sprinted maximally (30s Wingate), and the same leg was again occluded for 90s. Biopsies were taken from m. vastus lateralis at baseline, 20s after IE (occluded leg) and 10s after Wingate (occluded leg), and from the occluded and non-occluded leg at 90s and 30min post-Wingate. Protein expression was determined by western blot. Statistics: repeated-measures ANOVA.

RESULTS: Compared to the controls, the Zyt group showed increased basal protein expression of total Nrf2 ($P=0.099$), Thr287-CaMKIIδD (2-fold, $P=0.007$), Ser9-GSK3B (1.3-fold, $P=0.004$), and Ser40-Nrf2 (1.2-fold, $P=0.061$). In the control group, there was an upregulation with exercise and recovery of total Nrf2, Nrf2/Keap1 ratio, catalase, GR, and Thr287-CaMKIIδD protein expression (1.2-1.7-fold, all $P<0.05$; time x supplement interactions $P<0.05$). Thr180/Tyr182-p38 was similarly elevated in response to exercise and recovery in both groups ($P<0.001$, interaction $P=0.08$).

CONCLUSION: Zyt ingestion increases basal Nrf2 expression in skeletal muscle, likely by a mechanism involving activation of CaMKII, which phosphorylates GSK3B at Ser9, causing its inhibition. This mechanism impedes Nrf2 ubiquitination and proteasomal degradation elicited by GSK3B phosphorylation of β-TrCP. During exercise and recovery, Zyt supplementation blunts the Nrf2, catalase, GR, and CaMKIIδD responses, indicating a reduced signalling response to ROS. Therefore, this study demonstrates the antioxidant properties of Zynamite PX, which may explain its ergogenic and protective effects against eccentric-exercise muscle damage previously reported in humans.

AEROBIC EXERCISE TRAINING-INDUCED IRISIN SECRETION PREVENTS ATHEROSCLEROSIS WITH IMPROVEMENT OF ENDOTHELIAL FUNCTION IN APOE-DEFICIENT MICE

INOUE, K.1,2, FUJIE, S.1, UCHIDA, M.1, IEMITSU, M.1

1> RITSUMEIKAN UNIVERSITY, 2> RESEARCH FELLOW OF JAPAN SOCIETY FOR THE PROMOTION OF SCIENCE

INTRODUCTION: Endothelial dysfunction leads to the development of atherosclerosis because endothelial function regulates vascular homeostasis such as vasodilation, inhibition of inflammation responses, and suppression of smooth muscle cell proliferation. This function is mainly mediated by arterial nitric oxide (NO) produced by endothelial NO synthase (eNOS). Aerobic exercise training (AT) improves endothelial function via acceleration of NO production. Irisin is a myokine secreted from skeletal muscle and the secretion accelerated by habitual aerobic exercise. Moreover, irisin affects endothelial function via acceleration of NO production. However, it remains unclear whether AT-induced irisin secretion from skeletal muscle is involved in suppressing a progression of atherosclerosis. This study aimed to clarify whether irisin secretion is related to the suppression of atherosclerosis induced by AT.

METHODS: As an animal atherosclerosis model, 8-week-old apolipoprotein E (ApoE)-deficient mice were divided into 2 groups: ApoE-deficient sedentary group (ApoE-SED group: n=13) and ApoE-deficient aerobic exercise training group (ApoE-AT group: n=13, voluntary running exercise on a wheel for 16 weeks). ApoE-deficient mice were fed a high fat diet. In addition, normal diet-fed C57BL/6J mice were used as control sedentary group (WT-SED group: n=13). Aortic rings of each mouse were isolated for evaluation of acetylcholine-induced (endothelium-dependent) and sodium nitroprusside-induced vasorelaxation (endothelium-independent) using a wire myograph. Plasma irisin levels (ELISA) and arterial eNOS protein

expression (immunostaining) were measured. The one-way ANOVA was used to compare among 3 groups. Relationships between plasma irisin levels and eNOS expression or atherosclerotic lesion were determined using Pearson correlation coefficients. A $p<0.05$ was considered statistically significant.

RESULTS: In the ApoE-SED group, epididymal fat mass, plasma levels of LDL cholesterol and triglyceride, and fat accumulation of atherosclerotic lesion were significantly higher than those in the WT-SED group (each $p<0.05$). However, these parameters were significantly lower in the ApoE-AT group compared with the ApoE-SED group (each $p<0.05$). Additionally, plasma irisin levels, arterial eNOS protein expression, and endothelium-dependent vasorelaxation were significantly lower than those in the WT-SED group (each $p<0.05$), but these parameters were significantly higher in the ApoE-AT group compared with the ApoE-SED group (each $p<0.05$). No significant difference in endothelium-independent vasorelaxation among 3 groups were observed. Moreover, plasma irisin levels were positively correlated with arterial eNOS protein expression ($r=0.603$, $p<0.05$) and negatively correlated with fat accumulation of atherosclerotic lesion ($r=-0.838$, $p<0.05$).

CONCLUSION: These results suggest that AT-induced increase in irisin secretion may be involved in suppressing the progression of atherosclerosis with improvement of endothelial function.

THE IMPACT OF ALPHA-ACTININ-3 R577X AND ANGIOTENSIN-CONVERTING ENZYME I/D ON PHYSICAL FITNESS LEVELS AND ADAPTATION TO HIGH-INTENSITY RESISTANCE TRAINING IN PATIENTS WITH ANOREXIA NERVOSA.

PAGADOR, A.1, FERNANDEZ-DEL-VALLE, M.1, SANTIAGO, C.2, YVERT, T.3, GOMEZ-GALLEGO, F.4, GRAELL-BERNA, M.5, VILLASEÑOR, A.5, PEREZ, M.3

1. UNIVERSITY OF OVIEDO, 2. EUROPEAN UNIVERSITY, 3. UNIVERSIDAD POLITÉCNICA DE MADRID, 4. UNIVERSIDAD REY JUAN CARLOS, 5. HOSPITAL INFANTIL UNIVERSITARIO NIÑO JESÚS DE MADRID

INTRODUCTION: Muscle depletion accounts for 15-45% of the total body weight (BW) loss in patients with anorexia nervosa (AN). However, research has shown that up to 77% of the BW gains are achieved due to increases in fat mass while muscle tissue is not fully recovered [1]. Despite the known benefits of resistance training (RT) on muscular fitness (mass and function), the inclusion of patients with AN in RT programs has been controversial. Genetic factors – such as angiotensin-converting enzyme (ACE) and alpha-actinin-3 (ACTN3) R577X polymorphisms – have been linked to specific muscle phenotypes (i.e. mass, function) in several populations. This study aimed to analyze the distribution and influence of ACTN3 and ACE polymorphisms in physical fitness and adaptations to resistance training (RT) in AN.

METHODS: A total of 84 (age=13.5±1.2 years), 65 and 40 patients were included in the distribution, association and intervention analyses respectively. ACTN3 and ACE genotypes, body composition [including muscle cross-sectional-area (CSA)], strength and cardiorespiratory fitness were assessed.

RESULTS: ACE ID distribution was significantly different (37% vs. 50%, $p<0.001$) from general population. Association analyses showed significant differences in CSATHIGH (124.9±22.9cm2 RR, 139.0±22.9cm2 RX, 122.3±11.2cm2 XX, $p=0.039$) and Leg Press (LP) test (76.3±15.2kg RR, 89.21±18.9kg RX, 72.3±11.0 kg XX, $p=0.008$) between ACTN3 genotypes. Post hoc analysis showed significant differences (RR+RX>XX) in LP test. BW (48.8±6.8 kg DD, 45.2±7.5 kg ID, 41.63±6.7 kg II, $p=0.038$), CSAARM (25.9±7.1cm2 DD, 22.4±4.6cm2 ID, 19.6±5.5cm2 II, $p=0.021$) and LR (41.8±6.4kg DD, 35.2±6.8kg ID, 37.6±7.6kg II, $p=0.002$) were different when comparing ACE genotypes. Post hoc analysis confirmed significant differences (DD>II) for CSAARM and LR test. RT significantly improved body composition (i.e. BW, body mass index, muscle mass index, CSAARM and CSACALF) and strength (i.e. maximal and relative strength), without negative effects in body fat. Additionally, moderate-to-large effect sizes ($d=0.46–1.14$) were observed in muscular fitness (D vs. II, and R vs. XX) after intervention.

CONCLUSION: Our results suggest that patients with muscularity-power genotype (R and D allele carriers) maintain and/or improve muscle mass and function during hospitalization alone (without exercise) to a greater extent than those displaying non muscularity-power genotype (XX and II). Although all patients can benefit from RT regardless of their genotype, implementation of individualized high-intensity and high-frequency RT programs might be more critical for II and XX genotypes. This study uncovers a novel clinical application of individualized exercise programming – based on ACTN3 and/or ACE genotype – as complementary strategy to aid in the treatment in patients with AN. More research is needed to understand the impact of screening ACTN3 and ACE on individualized exercise programs in with AN during all treatment phases.

GENOME -WIDE ASSOCIATION STUDY FOR MUSCLE FIBER COMPOSITION IN JAPANESE POPULATION

TAKARAGAWA, M.1, ZEMPO, H.2, TOBINA, T.3, SHIOSE, K.4, KAKIGI, R.5, TSUZUKI, T.6, ICHINOSEKI-SEKINE, N.7, KUMAGAI, H.8, MIYAMOTO-MIKAMI, E.1, KOBAYASHI, H.9, NAITO, H.1, HANSSON, O.10, FUKU, N.1

1 JUNTENDO UNIV. , 2 TOKYO SEIEI COL., 3 NAGASAKI PREF. UNIV., 4 MIYAZAKI UNIV., 5 JOSAI INTL UNIV., 6 MEIJO UNIV., 7 THE OPEN UNIV. 8 SOUTHEM CALIFORNIA UNIV., 9 TSUKUBA UNIV., 10 LUND UNIV.

INTRODUCTION: Human skeletal muscle is composed of different fiber types, which are classified as type I (slow twitch) and/or type II (fast twitch). Although skeletal muscle fiber composition is largely affected by genetic factors, their details remain poorly understood. Here, we conducted a genome-wide association study (GWAS) to identify genetic polymorphisms associated with muscle fiber composition in humans.

METHODS: Step 1: Approximately 660,000 genetic polymorphisms were genotyped using the Japonica array and the proportion of myosin heavy chain isoform type I (MHC-I; an indicator of muscle fiber composition) in the vastus lateralis muscle of 214 Japanese individuals was analysed (men: n = 107; women: n = 107). Genome-wide associations for the proportion of MHC-I were assessed using a multiple linear regression model adjusted for age and sex. Step 2: To validate the possible associations observed in Step 1, meta-analyses were performed with an additional 656 Swedish individuals. Step 3: To examine the underlying mechanisms of their associations, differential gene expression analysis was performed by using RNA sequence data from the vastus lateralis muscles of 22 Japanese individuals.

RESULTS: Step 1: We detected 146 polymorphisms (for 28 genomic loci) associated with the MHC-I proportion that had a GWAS suggestive level ($P < 5\times10\text{-}5$), although none achieved the GWAS significance level ($P < 5\times10\text{-}8$). Step 2: In the Swedish cohort, 138 out of the 146 polymorphisms detected in Step 1 were found. Meta-analyses of the Swedish and Japanese cohorts revealed that 16 polymorphisms (four loci) were potential determining factors related to the proportion of MHC-I (Bonferroni adjusted $P < 3.6\times10\text{-}4 = 0.05/138$). A rs72558391 T/G (first locus) is located in TCN2. Other polymorphisms are located in intergenic region. Step 3: differential gene expression analysis showed that rs2378517 T/G (second locus), rs742739 C/T (third locus), and rs11071241 C/A (fourth locus) polymorphisms located in each intergenic region altered the gene expression profiles including CDKN1A, INO80B-WBP1, and 7SK, respectively.

CONCLUSION: We identified 16 novel polymorphisms (four loci) associated with muscle fiber composition.

ASSOCIATION BETWEEN THE GALNTL6 POLYMORPHISMS AND POWER-ORIENTED ATHLETES

KOZUMA, A.1, ZEMPO, H.2, SAITO, M.1, HOMMA, H.1, DEGUCHI, M.1, SAITO, A.1, MATSUMOTO, S.1, MATSUMOTO, R.3, OKAMOTO, T.1, NAKAZATO, K.1, KIKUCHI, N.1

1 NIPPON SPORT SCIENCE UNIVERSITY; 2 TOKYO SEIEI COLLEGE; 3 IKUEI UNIVERSITY

INTRODUCTION: N-acetylgalactosaminyltransferase-like 6 (GALNTL6) polymorphisms are associated with various categories such as memory, smoking behavior, and body size (GWAS catalog). Recently, the GALNTL6 rs558129 polymorphism has been associated with sports performance (Rankinen et al., 2016, Díaz Ramírezet al., 2020, Zmijewski et al., 2021). Therefore, this study aimed to compare the gene frequency of GALNTL6 rs558129 polymorphism between power-oriented athletes and controls (Study 1) and to detect other power athletic status-related genotypes by comprehensive polymorphism analysis in the GALNTL6 gene region in wrestlers and controls (Study 2).

METHODS: Study 1 enrolled 1,515 Japanese subjects, including 376 elite power-oriented athletes who competed in national and international competitions, including the Olympic games (257 men and 119 women), and 1,139 controls (448 men and 691 women). The sports practised by the power-oriented athletes were wrestling (n = 146), weightlifting (n = 151), and powerlifting (n = 79). The analysis of GALNTL6 rs558129 polymorphism was performed by TaqMan SNP Genotyping Assay using DNA extracted from saliva (Oragene-DNA Kit). Study 2 included 33 elite wrestlers and 211 controls, and the comprehensive polymorphism analysis was conducted. The comprehensive polymorphism analysis in the GALNTL6 gene region (162 SNPs) was genotyped using the Japonica Array v2. The p-value < 0.0003 (0.05/162) was considered statistically significant.

RESULTS: No significant difference in polymorphism frequencies between all power-oriented athletes and controls in Study 1 was found. On the other hand, the frequency of the TT genotype of rs558129 was significantly higher in wrestlers compared to that in the controls ($p = 0.044$). In the Study 2, there was no significant difference in GALNTL6 polymorphisms. The top SNP of the GALNTL6 polymorphisms were the rs10622983 polymorphism ($p = 0.002$).

CONCLUSION: The TT genotype of the GALNTL6 rs558129 polymorphism was only associated with wrestlers. Furthermore, GWAS showed that the GALNTL6 rs10622983 polymorphism was most relevant in wrestlers.

CP-PN08 Muscle damage and repair

MUSCLE FORCE PROFILES IN THE RAT TIBIALIS ANTERIOR AS A FUNCTION OF VARIOUS FREQUENCIES OF ECCENTRIC MUSCLE CONTRACTION

OGA, R.1, NAKAGAWA, K.1, HAYAO, K.2, TAMAKI, H.1

1 DEPARTMENT OF SPORTS AND LIFE SCIENCE, NATIONAL INSTITUTE OF FITNESS AND SPORTS IN KANOYA; 2 SOUTHERN TOHOKU GENERAL HOSPITAL

INTRODUCTION: High-intensity eccentric contractions (ECC) cause muscle damage and result in muscle function deficits. According to previous reports, prior ECC-induced muscle damage reduces the severity of subsequent muscle-damage symptoms. However, there remains a lack of understanding of the adaptations in muscle strength to the frequent performance of high-intensity ECC. We examined the effects of frequent ECC on the twitch and tetanic contraction forces in the rat tibialis anterior (TA).

METHODS: Thirty-two 12-week-old male Fischer 344 rats were assigned to one of seven groups: control with no intervention (Cont); single-bout of high-intensity ECC (1-bout); four weeks of high-intensity ECC with one repetition (1-bout_4w), two repetitions (2-bouts_4w), four repetitions (4-bouts_4w), or eight repetitions (8-bouts_4w); and an age-matched control

with no intervention (Cont_4w). The high-intensity ECC was elicited by tetanic electrical stimulation (ES) of the TA muscle. We first measured the twitch and tetanic contraction forces in the TA evoked by the ES, then harvested the TA after the four-week intervention period.

RESULTS: Maximal tetanic force, twitch force, and dP/dt in the 1-bout group were significantly smaller than in the Cont group. The maximal tetanic and twitch forces decreased exponentially ($R^2 = 0.80$) by approximately 40–50% and 10–50%, respectively, as the number of repetition counts increased. The dP/dt in all ECC groups decreased by approximately 20% relative to the Cont group.

CONCLUSION: These results suggest that a four-week ECC repetition intervention will reduce muscle contraction performance in the TA in accordance with the number of repetitions. Repeated high-intensity ECC interventions may reduce the force-generating capacity of the muscle fibers, resulting in an alteration in lower-limb muscle contractile properties.

INTRODUCTION: The integrity of the muscle mitochondria can be monitored by measuring striated muscle mitochondrial-specific isoenzyme, sarcomeric mitochondrial creatine kinase (sMtCK), which is extremely susceptible to oxidative damage [1]. Since oxidative stress (OS) is a dynamic process involving several pro-oxidant components, e.g., malondialdehyde, and anti-oxidant components, e.g., superoxide dismutase, integrative-based quantification methods such as OS index (OSI) may be used to fully understand the complex interaction between exercise-induced muscle damage and OS [2]. Therefore, the purpose of the research was to determine the OS time course induced by damage to muscle mitochondria and its relationship with muscle function following repeated sprint training (RST) in humans.

METHODS: Healthy males [n = 16, age = 22.4 ± 3.2 years, BMI = 23.8 ± 1.6 (mean ± SD)] and females [n = 14, age = 22.2 ± 3.1 years, BMI = 22.1 ± 2.3 (mean ± SD)] underwent 10 repeated 40-meters sprints with a 3-minute rest pause between repetitions. Serum biomarkers (sMtCK, OSI) and indirect indicators of muscle damage in lower limbs [force-generating capacity (FGC), range of motion (ROM)] were tested at baseline and during 72-hours post-RST. Participants whose sMtCK values at 72 hours were above the baseline values were grouped as high responders (HR), while the remaining participants were classified as low responders (LR). Three-way repeated measures ANOVA [time (pre, 24h, 48h, 72h) x group (HR, LR) x sex (female, male)] was conducted to identify the effect of time on serum biomarkers, FGC and ROM, followed by post-hoc Bonferroni-corrected paired t-test. Effect sizes (ES) were calculated using Cohen's d and associations between variables were analyzed using Spearman's Rho correlation coefficient. The level of significance was set at $p < 0.05$.

RESULTS: RST increased serum sMtCK by 244.9% in HR participants at 24h ($p < 0.001$; ES = 1.38) and remained elevated by 130.0% at 72 hours post-RST ($p < 0.001$; ES = 1.13), so the model was effective in damaging mitochondrial structure. In this way, OSI was increased and remained elevated at +72h in HR group ($p < 0.001$; ES = 1.20). There were no differences between sex in the interaction of time and group for sMtCK ($p = 0.268$) and OSI ($p = 0.153$). Moreover, peak sMtCK was positively correlated to peak OSI ($r = 0.712$, $p < 0.001$). Finally, HR participants reported both a decrease in FGC at 48 hours of 17.3% ($p = 0.003$; ES = 0.61), which remained decreased by 16.4% ($p = 0.003$; ES = 0.96) at 72 hours post-RST, and a decrease in ROM during the 72 hours recovery period.

CONCLUSION: RST is an effective model to generate moderate damage to muscle mitochondria and associated oxidative stress in HR individuals. Further, FGC and ROM remain impaired during the 3-day post-RST recovery period.

ASSOCIATION BETWEEN TOTAL GENOTYPE SCORE AND MUSCLE INJURIES IN TOP-LEVEL FOOTBALL PLAYERS: A PILOT STUDY

MASSIDDA, M.1,2, FLORE, L.1, CUGIA, P.2, PIRAS, F.2, SCORCU, M.2, KIKUCHI, N.3, CIESZCZYK, P.4, MACIEJEWSKA-SKRENDO, A.4, TOCCO, F.1,2, CALO, C.M.1

1UNIVERSITY OF CAGLIARI, ITALY; 2ITALIAN FEDERATION OF SPORT MEDICINE, ROME, ITALY; 3NIPPON SPORT SCIENCE UNIVERSITY TOKYO, JAPAN; 4UNIVERSITY OF PHYSICAL EDUCATION AND SPORT, GDAŃSK, POLAND

INTRODUCTION: Recently, genetic predisposition to injury has become a popular area of research and the association between a few Single Nucleotide Polymorphisms (SNPs) and the susceptibility to develop muscle injuries in football has been shown (1,2). This pilot study aimed to investigate the combined influence of common gene polymorphisms previously associated with muscle injuries in Italian football players.

METHODS: Total of 64 Italian top-level football players (age 23.1±5.5years; height 179.3±7.3cm; weight 73.0±7.9kg) were genotyped for 4 gene polymorphisms (ACE I/D rs 4341, ACTN-3 R/X rs 1815739, COL5A1 C/T rs 12722, MCT1 A/T rs1049434). Genomic DNA was extracted using a buccal swab, and genotyping was performed using a PCR method. Structural-mechanical injuries and functional muscle disorders were collected over 10 years (2009-2019).

RESULTS: Logistic regression analyses showed a significant association of all four polymorphisms with muscle injury incidence (P<0.01), while the ACTN-3 and the COL5A1 polymorphisms were significantly associated with the severity of injury (P = 0.042 and P = 0.012, respectively). Moreover, the mean total genotype score (TGS) was significantly higher in injured than in non-injured (control) football players (Injured: 57.5±15.5 vs non-injured: 36.6±13.7, t=6.33, P<0.001) and it was a strong predictor of muscle injury (OR=2.93, 95%CI: 0.06-0.18, P>0.001).

CONCLUSION: These data suggest that the carriage of a high number of "protective" gene variants could influence the individual susceptibility to develop muscle injuries in football. Further studies are needed to confirm these findings in other professional football player cohorts.

INTRODUCTION: Passive muscle stiffness is suggested to influence the risk of muscle strain injury. Identifying the biological mechanisms determining individual muscle stiffness differences may thus contribute to the development of preventive approaches for muscle strain injury. To identify the genetic underpinnings of muscle stiffness, we performed a genome-wide association study (GWAS) (Step 1), followed by an association analysis of the identified loci with muscle strain injury in athletes (Step 2).

METHODS: Step 1: A GWAS for passive muscle stiffness in the biceps femoris long head (BFlh) was performed in 365 Japanese individuals (males: n = 223, females n = 142). Passive BFlh stiffness of the right leg was assessed using ultrasound shear wave elastography. All participants were genotyped for approximately 660,000 single nucleotide polymorphisms (SNPs) using the ethnicity-specific Japonica Array. Standard quality controls (QC) and imputation with the 3.5KJPN haplotype reference panel were performed. Genome-wide associations for passive BFlh stiffness were tested under an additive genetic model using a linear regression analysis adjusted for sex, age, and stretching exercise habit. The genome-wide significance level was set at $P < 5\times10\text{-}8$. Step 2: SNPs with $P < 5\times10\text{-}8$ in Step 1 were tested for associations with muscle strain injury in 1127 Japanese athletes (males: n = 759, females: n = 368) from various sports. The history of muscle strain injury was assessed using a questionnaire. Genotyping of all athletes was performed using the same method as in Step 1.

RESULTS: Step 1: After QC, 5,414,785 autosomal SNPs in 365 individuals were available for analysis. Six SNPs in two loci on chromosome 11 were significantly associated with passive BFlh stiffness ($P < 5\times10\text{-}8$). The first locus contained five SNPs located an intergenic region, and the second locus contains a single SNP located within CCDC73. Step 2: The top SNP (rs61908632 C/T) of the first locus was significantly associated with muscle strain injury in athletes (P = 0.027 by logistic regression analysis adjusted for age, sex, and sporting event), where T allele (muscle stiffness-increasing allele) carriers exhibited a higher frequency of athletes with muscle strain injury (Odds ratio: 1.70, 95% confidence interval: 1.08–2.66, under a T-allele additive genetic model). No association was observed between the second locus and muscle strain injury.

CONCLUSION: The unbiased GWAS for passive muscle stiffness identified a novel locus related to the risk of muscle strain injury, which deserves further exploration for the underlying molecular mechanisms.

IMPROVING RETURN TO PLAY: INTERMITTENT HYPOBARIC HYPOXIA EXPOSURE ACCELERATES SKELETAL MUSCLE RECOVERY

SANTOCILDES, G., VISCOR, G., PAGÈS, T., TORRELLA, J.R.

UNIVERSITAT DE BARCELONA

INTRODUCTION: Muscle injuries are one of the main causes of injury suffered in sport. Due to its high incidence and impact on the athletes´ career, the muscle regeneration process has been widely studied and characterized. However, it has not been proposed yet a gold standard therapy that allows accelerating the muscle regeneration and reducing the rate of re-injury. Intermittent hypobaric hypoxia (IHH) has been used as a tool to improve performance of athletes, because of the adaptations that IHH can elicit on muscle tissue to maintain muscle homeostasis and functionality when oxygen availability is reduced. We hypothesize that IHH may also be a suitable therapy to enhance the muscle regeneration process and our main objective was to assess the time course of some muscle functional parameters and several regeneration markers after an IHH recovery protocol.

METHODS: Eighteen adult male rats were surgically injured in the right gastrocnemius muscle and randomly divided into two groups; 1) Control group (CTRL), with passive recovery in normoxia; 2) Hypoxic group (HYPO), subjected to IHH 4h/day into a hypobaric chamber (simulated altitude of 4,500 m). Muscle functional properties: peak force (PF), tetanic force (TF)

and low frequency fatigue resistance at 30 Hz (LFF) of injured and contralateral non-injured gastrocnemius muscles were measured in vivo at 9 and 21 days after injury. Collagen I deposition and developmental myosin heavy chain (dMHC) expression at the injury site were measured in histological slides. AKT, mTOR and AMPK protein expression were analysed by Western blot.

RESULTS: CTRL animals presented significant reductions in the functional parameters of the injured gastrocnemius at both time points (PF: 9 days: p=0.012; 21 days: p=0.049; TF: 9 days: p=0.034; 21 days: p=0.024; LFF: 9 days: p=0.053; 21 days: 0.038). However, HYPO animals showed a full recovery. After 9 days of IHH a significant reduction in dMHC expression (p=0.004) and collagen I deposition (p=0.012) compared to CTRL was shown at the injury site. On the other hand, in the injured muscle, HYPO showed a significantly higher expression of the pSer473Akt/total Akt ratio at 9 days (p=0.002), and a higher expression of the pThr172AMPKα/total AMPKα ratio (9 days: p=0.066; 21 days: p<0.001) than CTRL. However, no significant changes where found between groups in pSer2448mTOR/mTOR total ratio at any time point studied.

CONCLUSION: IHH accelerates muscle regeneration in rats as early as after 9 days of treatment, which was evidenced by the recovery of muscle functionality, by a fast maturation of newly formed muscle fibres (reduction of the dMHC positive fibres) and by the reduction of collagen deposition. Our results also suggest that the overexpression of AKT and AMPK proteins (involved in muscle regeneration processes) could play a role in the early recovery of the injured muscle.

ACUTE MELATONIN ADMINISTRATION AFTER PHYSICAL EXERCISE-INDUCED SKELETAL MUSCLE DAMAGE ON PAX7

BECK, W.R., FARIA, V.S., MANCHADO-GOBATTO, F.B., ZAGATTO, A.M., CORNACHIONE, A.S., INFANTE, N.A.

FEDERAL UNIVERSITY OF SÃO CARLOS

INTRODUCTION: High intensity and/or duration of physical exercise generally leads to skeletal muscle damage, which can be observed until days after exercise through PAX7 quantity at muscle cells nucleus, denoting the stage of repair process. The muscle repair is highly involved with cell redox and inflammation state, and melatonin has relevant anti-inflammatory and antioxidant effect, potentially influencing such process. So, we aimed to investigate the effect of melatonin on nucleus myocyte PAX7 in rats submitted to a skeletal muscle damage induction protocol (DIP) prescribed through individually determined exercise intensity in swimming rats.

METHODS: Thirty male Wistar rats were exposed to a light/dark cycle (10/14h) and had their daily spontaneous physical activity gravimetrically determined to set the time of day for interventions, which were performed at wakefulness period under ~15 lux and 600 nm light. At 75 days-old was started the aquatic adaptation to proceed with the graded exercise test (GET) two weeks later. The GET consisted in 5-min stages from 4 to 7% of body mass (%BM), with 0.5%BM increments. Blood was collected to determine the lactacidemic anaerobic threshold (L2, corresponding to maximal lactate steady state intensity). At 97 days-old was conducted the DIP, consisted of 1-min 10 swimming bouts at 120% L2, with a 30-s interval, followed by 20 minutes of continuous swimming at 100% of L2. Immediately after DIP, vehicle solution (C) or melatonin (M; I.P. 10 mg.kg-1) was administered, and the 5 animals per group were euthanized 24 (C24 or M24), 48 (C48 or M48) or 72h after (C72 or M72). White portion of the gastrocnemius muscles were collected to determine PAX7 using immunofluorescence on transverse sections of muscle (6µm) transferred on glass slides. The quantification of PAX7 was performed analyzing the overlap between PAX7 and nucleus markings as well as their intracellular location in relation to laminin. Data were presented as mean ± standard error and significance set at P<0.05. Two-way ANOVA was used to analyze the effects of melatonin (melatonin or vehicle) and time (24, 48 or 72 h), with Newmann-Keuls post hoc.

RESULTS: The peak of spontaneous physical activity was found 3 hours after the start of dark cycle, the time when the procedures were started. The L2 of all groups was 5.63±0.69 %BM and all animals performed the full PID. PAX7 was 9.08±1.36, 10.02±0.50, and 6.94±1.15 to C24, C48 and C72, and 4.09±0.61 to M24, 5.20±0.70 to M48 and 5.33±0.64 PAX/Muscle fiber.103 to M72, with area under the curve 44.1% higher to vehicle in relation to melatonin treatment. Was find melatonin effect on PAX7 (C>M; F=13.90; p<0.01), but no effect of time (F=0.73; p>0.05).

CONCLUSION: Exogenous melatonin administered just after the individually prescribed PID had no relevant effect on the time to peak for PAX7 but reduced the activated PAX7 at muscle nucleus in relation to vehicle solution.

Supported by FAPESP 2019/08148-3 and 2023/00651-3.

THE EFFECT OF CAPSAICIN APPLICATION TO THE SKIN ON SYMPTOMS OF EXERCISE INDUCED MUSCLE DAMAGE

GELADAS, N., KOTSONI, A., BOTONIS, P., PASCHALIS, V.

PHYSICAL EDUCATION AND SPORT SCIENCE

INTRODUCTION: Intense eccentric exercise has been documented to induce muscle damage (EIMD), which is typically manifested by a decrease in the range motion (ROM), reduction of produced muscular force as well as by delayed onset of muscle pain (DOMS) and swelling. Cryotherapy has been suggested as an effective mode of enhancing recovery after EIMD but this approach is highly controversial. On the other hand, recent preliminary findings suggest that thermotherapy may be an alternative intervention for faster recovery after EIMD. The purpose of this study was to determine whether thermotherapy, by means of capsaicin application to the skin, could be an effective strategy to accelerate skeletal muscle recovery following eccentric exercise and enhance performance in subsequent muscular efforts.

METHODS: Twenty-nine healthy, physically active young men underwent eccentric exercise consisted of 6 sets times 20 single-legged drop jumps-from a raised platform (0.20m high) with a 2-minutes break between each set. The eccentric exercise session was performed twice, one for the placebo (PL) and the other for the thermal therapy (HT) using a different

randomly selected leg in each occasion. A two weeks interval was used between the two therapies. The thermal therapy included capsaicin patches (capsicum extract 0,025%) placed for 48 h post exercise on the exercised muscle groups (i.e., quadriceps femoris). Muscle damage indices [i.e. DOMS, ROM, and squat jump (SJ)] were assessed before each eccentric exercise and 48 hours after either placebo or capsaicin therapy. At the same time points, assessment of muscle oxygenation was also performed, using near infrared spectroscopy (NIRS; vastus lateralis).

RESULTS: The eccentric exercise protocol induced significant alterations in all muscle damage indices [i.e., DOMS, ROM and SJ) after both conditions ($p<0.05$). However, DOMS was lower after the heat therapy compared to the placebo therapy ($p<0.026$). No differences were recorded between experimental conditions with regard to local muscular hemodynamics, leaping and range of motion abilities.

CONCLUSION: Despite that the application of capsaicin patches on the skin after intense eccentric exercise has an analgesic effect it does not appear to improve subsequent exercise performance. The analgesic effect of capsaicin application to the skin might be due to the stimulation of thermo sensitive TRPV-1 channels. The unchanged exercise performance following capsaicin treatment remains to be resolved.

EFFECT OF SPERMIDINE SUPPLEMENTATION ON SKELETAL MUSCLE REGENERATION AFTER INJURY

IWATA, T.

UNIVERSITY OF TSUKUBA

INTRODUCTION: Athletes practice hard every day to improve their performance. Many athletes experience sports injuries mainly caused by repetitive movements and local overactivity. Establishment of injury prevention, treatment, return to sports and prevention of recurrence are urgent issues. Particulary, "muscle strain" is one of the skeletal muscle injuries, and many athletes suffer because sports activities are greatly restricted during treatment, the period of treatment is long, and the risk of recurrence is high. Spermidine is a type of polyamine contained in foods such as cheese or soybean, and various health functions through oral intake have been reported previously (Madeo et al., 2017). Recently, spermidine intake was shown to promote regeneration of skin after injury (Ito et al., 2021). However, it is unclear whether spermidine intake promotes regeneration of skeletal muscle after injury.

METHODS: Eight-weeks-old C57BL/6j male mice were divided into two groups: the DW group, which was allowed to ingest distilled water (DW) ad libitum, and the SP group, which was allowed to ingest spermidine (SP) mixed with DW to a concentration of 5 mM. Skeletal muscle injury was induced by cardiotoxin (CTX) (10 μM/50 μL in PBS) injection into the left tibialis anterior muscle. Right tibialis anterior muscle was injected with PBS (50 μL) as a control. SP group started taking spermidine-mixed water on the day of injection, and the water was changed every other day. Tibialis anterior muscle was isolated from the mice, 4 and 7 days after the CTX injection and analyzed.

RESULTS: We performed immunohistochemical staining of Laminin-α2, DAPI, and Collagen-1 using muscle sections of tibialis anterior. SP group tended to show lower myofiber CSA than that of DW group in 7 days, but no difference are detected in 4 days. We found no significant changes between the group in the area of fibrosis at 4 and 7 days after injury. We found some significant changes in the autophagy related proteins.

CONCLUSION: Our data suggested that spermidine delays the early stages of skeletal muscle regeneration after injury. Spermidine exerts diverse health functions through activating autophagy (Madeo et al., 2017). Previous studies have shown that the activation of autophagy by genetic modification promoted the recovery of skeletal muscle wet weight in 14 days and myofiber CSA in 21 days after injury(You et al., 2021). Thus, examination of autophagy related proteins in longer period of recovery are required.

NEUROMUSCULAR AND METABOLIC RESPONSES DURING REPEATED BOUTS OF OVERWEIGHTED DOWNHILL WALKING

CHALCHAT, E.1,2, SIRACUSA, J.1,3, PEÑAILILLO, L.4, MALGOYRE, A.1,3, BOURRILHON, C.1,3, CHARLOT, K.1,3, MARTIN, V.2,5, GARCIA-VICENCIO, S.1,2,6

1: INSTITUT DE RECHERCHE BIOMÉDICALE DES ARMÉES; 2: AME2P LAB; 3: LBEPS, UNIV EVRY; 4: UNIVERSIDAD ANDRES BELLO, 5: INSTITUT UNIVERSITAIRE DE FRANCE, 6: HUMAN MOTION ANALYSIS, HUMANFAB

INTRODUCTION: It has been well established that performing a bout of unaccustomed, predominantly eccentric exercise may result in a long-lasting muscle function deficit (>24 h) and in a set of symptoms (e.g., muscle soreness, increased levels of circulating proteins). It is also well established that repeating the same bout within few weeks results in reduced loss of muscle function and symptoms of muscle damage compared to the initial bout. It has been suggested that neural, mechanical and cellular adaptations may explain the protection conferred by a single bout of eccentric exercise, called the "repeated bout effect". Some authors suggested an enhanced efficiency (i.e., lesser muscle activity and/or energy expenditure for the same power output) during a second bout of eccentric exercise. It has been shown that neural and mechanical adaptations could be involved in the enhanced efficiency, however there is no consensus. Moreover, it is not known how neuromuscular and metabolic responses could adapt in response to downhill walking/running, a more functional and accessible task compared to traditional one-limb eccentric exercise on an ergometer. The aim of this study was to compare the neuromuscular (i.e., fascicle behavior and muscle activation), cardio-respiratory and fatigue-perceived changes during repeated bouts of downhill walking with load carriage.

METHODS: 17 participants performed two sessions of 45-min loaded downhill walking (DW) separated by 2 weeks. Rating of perceived exertion (RPE), cost of walking (Cw), heart rate (HR), muscle activation of the vastus lateralis (VL), rectus femoris (RF) and biceps femoris (BF), and muscle fascicle behavior of the VL were assessed during the downhill walking. Maximal

voluntary contraction (MVC) torque and muscle soreness, were assessed before (PRE), immediately after (POST), and 24 and 48 h after the two exercise bouts.

RESULTS: MVC torque measured 24 h after the DW was reduced by 25.5 ± 10.3 % and 5.2 ± 13.2 % for the first (DW1) and the second (DW2) DW respectively. Muscle soreness was also significantly reduced after DW2 compared to DW1 ($p < 0.01$). RPE, cardiorespiratory (HR and Cw) and RF muscle activation were significantly decreased during DW2 compared to DW1 ($p < 0.05$). Moreover, VL fascicle elongation was higher during DW2 compared to DW1 ($p < 0.05$).

CONCLUSION: As expected, we found a reduced loss of muscle function and symptoms of muscle damage after the second bout compared to the initial bout of downhill walking. Protective adaptations conferred by the first bout induce a lower perceived exertion and cardiorespiratory responses when the same exercise is repeated within few weeks. Neural and mechanical adaptations could partly explain the lower perceptual and cardio-respiratory responses during a second bout of eccentric biased exercise.

THE EFFECT OF LIFELONG ENDURANCE TRAINING ON MORNING CORTISOL LEVEL AND SELECTED MARKERS OF STRESS RESPONSE AND INFLAMMATION

CERNÁCKOVÁ, A.1, SEDLIAK, M.1, ORESKÁ, L.1, BUZGO, G.1, HAMAR, D.1, CVECKA, J.1, KERN, H.3, OKULIAROVA, M.2, ZEMAN, M.2

COMENIUS UNIVERSITY IN BRATISLAVA, 1 FACULTY OF PHYSICAL EDUCATION AND SPORT, 2 FACULTY OF NATURAL SCIENCES, BRATISLAVA, SLOVAKIA, 3 INSTITUTE FOR PMPR, ST. PÖLTEN, AUSTRIA

INTRODUCTION: Aging is associated with changes at all levels of living organisms, including hypothalamic-pituitary-adrenocortical (HPA) axis. Altered function of the HPA axis can modify the bodys response to stress, but it also affects other organ systems, including the nervous, hormonal and immune system. Via this connection, the proper function of the HPA axis has a fundamental impact on human health. Regular physical activity may have a protective effect on the age-related disruption of HPA axis function. Therefore, the aim of our study was to determine whether lifelong physical activity can affect morning cortisol level, selected parameters of the stress response and inflammatory markers.

METHODS: 42 healthy male subjects were divided to four groups according to age and physical activity: young athletes (YA, age 28.20 ± 0.65, BMI 21.89 ± 0.36, n=11), young sedentary (YS, age 25.55 ± 0.71, BMI 27.78 ± 1.57, n=11), elderly athletes (EA, age 69.0 ± 0.98, BMI 24.35 ± 0.79, n=10), elderly sedentary (ES, age 71.10 ± 1.15, BMI 27.74 ± 0.79, n=10). Participants included in the group of athletes had to perform more than 300 min/week of endurance running activity and participate in running competitions. Blood was drawn at 7:30 a.m. and it was evaluated for concentrations of cortisol, C-reactive protein (CRP), and neutrophil to lymphocyte ratio (NLR) in a commercial laboratory. Two-way ANOVA followed by Bonferroni post-hoc test with the factors age and exercise was used as a statistical method. Data are expressed as mean ± SEM.

RESULTS: We did not demonstrate a significant effect of older age ($p=0.183$) or regular physical activity ($p=0.151$) on morning cortisol concentrations. For NLR, we proved significant effect of aging ($p=0.002$) and regular endurance training ($p=0.031$). Moreover, two-way ANOVA provided proof for protective effect of regular endurance training on NLR between two groups of elderly (EA vs. ES: 1.84 ± 0.23 vs. 2.47 ± 0.25, $p=0.032$). Older age was also associated with higher CRP concentrations ($p= 0.002$), while we did not demonstrate a protective effect of regular endurance activity as prevention of inflammation ($p= 0.474$). Indeed, we proved elevated levels of CRP in elderly groups of athletes (EA vs. YA: 1.73 ± 0.80 vs. 0.31 ± 0.06 mg/l, $p=0.042$) as well as sedentary (ES vs. YS: 2.56 ± 0.76 vs. 1.42 ± 0.82 mg/l, $p=0.014$) when compared to young groups.

CONCLUSION: Although we did not demonstrate an effect of long-term endurance training on morning cortisol and CRP concentrations, we found interesting results in NLR. NLR can serve as a measure of chronic stress and subclinical inflammation. The values of NLR in ES group corresponded to the "grey zone" and may be associated with the development of several diseases. However, negative effect of aging on worse NLR seems to be blunted by lifelong endurance training.

The study was supported by the INTERREG V-A Slovakia—Austria (acronym CAA, ITMS2014 + 305041X157) and by the Slovak Research and Development Agency (Grant no. APVV-21-0164).

HAIR ANALYSIS FOR SPORTS DRUG TESTING USING UPLC-MS/MS IN A RAT MODEL: COMPARISON WITH PLASMA AND URINE

HUNG, S.H.1, TIAN, C.2, CHANG, W.C.W.1,2

KAOHSIUNG MEDICAL UNIVERSITY, KAOHSIUNG CITY 807378, TAIWAN

INTRODUCTION: Currently, sports drug testing primarily analyzes urine and blood samples from athletes; however, these liquid matrices mainly provide short-term usage information and are not easily stored and transported. In contrast, hair analysis provides long-term usage information for an average of several months. This study will be the first to systematically evaluate different types of all-time prohibited substances in a rat model to investigate the correlation between expo-

sure levels and the concentration of prohibited substances in the hair, as well as the association of prohibited substances in the hair with urine and plasma.

METHODS: In this study, hair, plasma and urine were collected from SD rats during a 28-day control period for 18 representative all-time prohibited substances in 4 types (S1 anabolic agents, S3 beta-2 agonists, S4 hormone and metabolic modulators, and S5 diuretics and masking agents) at 4 different doses (0, 1, 2, and 4 mg/kg). After pre-treatment, the samples were analyzed by ultra performance liquid chromatography - tandem mass spectrometer (UPLC-MS/MS) with ESI and the data were processed by MassLynx® software for semi-quantification of the 18 all-time prohibited substances in different matrices using a quantification line.

RESULTS: More than half of the 18 representative all-time prohibited substances were found to be linear (>0.99) using hair, urine and plasma, and three biological samples were able to reach the sub-parts-per-billion (sub-ppb) level of quantification using this method. Hair samples from the back of rats (13.1 ppb-1080.80 ppb) were actually analyzed after 28 days of controlled intake of 18 all-time prohibited substances.

CONCLUSION: Although not much research has been done on hair analysis related to prohibited substances in sports until now, the results of this study suggested that the use of hair analysis in sports drug testing can help to complement the current doping control in increasingly diverse cases of prohibited substances. More research is needed to develop the multiple application of this analytical method before it can be used in doping control to help maintain fair competition.

O2 SUPPLEMENTATION IMPROVES OXYGEN-UPTAKE KINETICS AND EXERCISE CAPACITY IN PATIENTS WITH INTERSTITIAL LUNG DISEASE (ILD)

REUVENY, R.1, BAIDATS, Y.2,3, KADOSH, S.2,3, JONES, M.A.4, WILKERSON, D.4, VELNER, A.2, SEGEL, J.M.2,3

1. UNIVERSITY OF HAIFA 2. SHEBA TEL HASHOMER MEDICAL CENTER 3. TEL-AVIV UNIVERSITY 4. UNIVERSITY OF EXETER

INTRODUCTION: Oxygen (O2) therapy is commonly prescribed for patients with moderate to severe interstitial lung disease (ILD). The precise physiological mechanisms by which ILD patients benefit from O2 during exercise are not clear.

Purpose: We studied the effect of O2 supplementation on exercise physiology in ILD patients.

METHODS: 12 patients (age = 67±10 yrs., 6 males), with moderate to severe ILD (TLC = 67±17% predicted, DLCO = 43±17% predicted) and 11 healthy individuals (age = 51±17 yrs., 7 males,) were tested. ILD patients performed symptom-limited cardiopulmonary exercise tests and constant work-rate tests (CWRTs) at 80% of the work-rate (WR) at the gas exchange threshold (GET) room air (RA, FiO2 = 0.21) were compared to tests performed breathing 30% O2 (FiO2 = 0.30), a clinically relevant level of hyperoxia. Healthy individuals performed a maximal test only with FiO2 = 0.21 and a CWRTs under both conditions (FIO2 = 0.21 and FIO2 = 0.30). Oxygen-uptake (VO2) kinetics were calculated from the CWRTs results using mono-exponential modelling.

RESULTS: In the ILD group, peak WR and peak VO2 improved significantly when breathing with FIO2=0.3 compared to RA (mean ± SD 62±21 vs 73±27 watts and 14.4±2.5 vs 16.7±3.6 ml/kg/min, p=0.005 and p=0.002, respectively). VO2 at the GET was higher with FIO2=0.3 compared to FIO2=0.21 (829±247 vs 751±234 ml/min, p=0.009). O2 saturation (SPO2 %) at peak exercise was higher with FIO2=0.3 (97±4% vs 88±10%, p=0.004). The time constant (tau) of mono-exponential fits of phase II of VO2 kinetics in CWRTs was faster in ILD patients while breathing with FIO2=0.3 (42±10 sec) compared to RA (52±15 sec, p=0.005). The O2 deficit in the CWRTs was lower while breathing with FIO2=0.3 (0.47±0.14) compared to RA (0.53±0.14) p=0.03. SPO2 % during CWRTs was higher with FIO2=0.3 compared to FIO2 = 0.21 (99±2% vs 93±7%, p=0.004). There was a negative linear relation between tau and SPO2% with RA (r=-0.76, p=0.006) and while breathing with FIO2=0.3 (r=-0.68, p=0.02). There was no difference in VO2 kinetics in healthy individuals between FiO2=0.21 and 0.30 (tau 34±6 sec vs 35±6 sec, p=NS).

CONCLUSION: Using a clinically relevant level of O2 supplementation (30%) improved maximal exercise capacity and oxygen-uptake kinetics in ILD patients, apparently by increasing blood O2 content, thus presumably increasing muscle oxygen delivery. This finding has a clinical value for ILD patients.

EFFECT OF EXERCISE TRAINING ON PROGNOSIS IN COMMUNITY-ACQUIRED PNEUMONIA: A RANDOMISED CONTROLLED TRIAL

RYRSØ, C.K., FAURHOLT-JEPSEN, D., RITZ, C., HEGELUND, M.H., DUNGU, A.M., PEDERSEN, B.K., KROGH-MADSEN, R., LINDEGAARD, B.

RIGSHOSPITALET, UNIVERSITY OF COPENHAGEN

INTRODUCTION: Physical inactivity is common during hospital admission with community-acquired pneumonia (CAP) and is associated with an increased risk of adverse outcomes. The aim was to investigate the effect of supervised exercise training during admission with CAP on prognosis.

METHODS: with CAP was conducted at the Copenhagen University Hospital – North Zealand, Denmark, from April 2019 to March 2022. Patients were randomly assigned in a 1:1:1 ratio to either standard of care, standard of care combined with supervised in-bed cycling, or standard of care combined with supervised exercise training, according to a booklet. The primary outcome was length of stay. Secondary outcomes were 90-day readmission and 180-day mortality. Analysis of covariance was used to determine differences in length of stay. Cox proportional hazards regression was used to assess the risk of readmission and mortality.

RESULTS: In the intention-to-treat analysis, length of stay was similar between the standard of care and the in-bed cycling (-2%, 95% CI -24 to 25%, P=0.85) and booklet exercise groups (-1%, 95% CI -22 to 27%, P=0.94). In the available-case analysis, the adjusted hazard ratio for 90-day readmission was 0.63 (95 % CI 0.33–1.21, P=0.17) for the in-bed cycling and 0.54 (95% CI 0.27–1.08, P=0.08) for the booklet exercise groups, compared to standard of care. Post-hoc subgroup analysis showed a significant reduction in 90-day readmission risk with booklet exercise for ≥10 min per day during admission (hazard ratio 0.41, 95% CI 0.18–0.93, P=0.03). The risk of 180-day mortality was similar between the standard of care and the in-bed cycling (adjusted hazard ratio 0.84, 95% CI 0.27–2.60, P=0.76) and booklet exercise groups (adjusted hazard ratio 0.82, 95% CI 0.26–2.55, P=0.73).

CONCLUSION: Supervised exercise training during admission with CAP had no effect on the length of stay and mortality. Subgroup analyses demonstrated a reduced risk of readmission with booklet exercises. Exercise training during admission could be a safe strategy to mitigate the vicious cycle of readmissions in patients with CAP.

BLOOD-FLOW RESTRICTED INTERVAL CYCLING MAXIMIZES LEG MUSCLE EFFORT WITH LESS VENTILATORY WORK COMPARED TO WORK-MATCHED FREE-FLOW EXERCISE: A RANDOMIZED CROSSOVER STUDY

KUHN, M., CLARENBACH, C.F., KLÄY, A., RADTKE, T., HAILE, S.R., SIEVI, N.A., KOHLBRENNER, D.

UNIVERSITY HOSPITAL ZURICH

INTRODUCTION: Endurance training with blood flow restriction (BFR-EN) can improve muscular function and aerobic capacity. We investigated the acute cardiorespiratory response between BFR-EN and traditional interval endurance exercise (TRA-EN). We hypothesized that BFR-EN elicits lower minute ventilation (VE, primary endpoint) while exacerbating perceived leg exertion compared to work-matched TRA-EN.

METHODS: We conducted a randomized crossover study. The protocol involved three cycling intervals interspersed by 1 min resting periods. Respiratory parameters were collected by breath-by-breath analysis. Heart rate (HR) and rate of perceived exertion (RPE, scale from 0 to 10) were assessed. TRA-EN intervals lasted 2 min with an intensity of 65% peak workload. BFR-EN intervals were work-matched to TRA-EN and, thus, lasted 2 min 18 sec with an intensity of 50% peak workload. Arterial occlusion pressure (AOP) was determined before the exercise sessions and 50% occlusion was continuously applied during the BFR-EN condition on both legs. Linear mixed models were used to analyze all metabolic, HR, and RPE data adjusted for multiple measurements and reported as mean differences [95% confidence interval].

RESULTS: Twenty-four healthy individuals (male/female: 15/9, mean (SD) age: 30.5±8.3 yrs, mean (SD) peak oxygen consumption (VO2peak): 45.7±9.9 mL/kg/min) completed the study. TRA-EN elicited higher VE (2.4 L/min [0.98 to 3.82]), oxygen consumption (2.47 mL/kg/min [2.02. to 2.93]), carbon dioxide production (0.2 L/min [0.17 to 0.22]), RPE Dyspnea (0.7 [0.55 to 0.85]) and HR (4.5 bpm [1.71 to 7.2]) compared to BFR-EN. RPE Leg (-1.24 [-1.46 to -1.03]) was lower in TRA-EN compared to BFR-EN.

CONCLUSION: BFR-EN at 50% peak workload and 50% AOP resulted in lower VE and perceived dyspnoea compared to TRA-EN at 65% peak workload. For people with short-term lung restriction (e.g. shortly after a cold) or with lung disease BFR-EN could provide endurance training with less respiratory effort while augmenting leg muscle effort.

THE RUNNING INJURY CONTINUUM: AN EXAMINATION OF RECREATIONAL RUNNERS' DESCRIPTION AND MANAGEMENT OF INJURY

LACEY, A., WHYTE, E., O'KEEFFE, S., O'CONNOR, S., BURKE, A., MORAN, K.

DUBLIN CITY UNIVERSITY

INTRODUCTION: A critical step in understanding and preventing running-related injuries (RRIs) is appropriately defining RRIs [1]. Current definitions of RRIs may not represent the process of injury development, failing to capture lower level injuries that athletes train through [2]. Understanding runners' description of injury may allow for appropriate examination of all levels of injury. The aim of this study was to examine recreational runners' description and management of the injury development process.

METHODS: A qualitative study with seven semi-structured focus groups including 31 recreational runners (13 male and 18 female) took place. Focus groups were audio and video recorded, and transcribed verbatim. Transcripts were reflexively thematically analysed. A critical friend approach was taken to data coding, and multiple methods of trustworthiness were executed.

RESULTS: Runners describe a nine-level continuum of injury, with lower and higher level injuries identified. They nine levels of injury are: Running smooth, Discomfort, Niggle, Twinge, Persistent niggle, Non-responsive injury, Injury: short-term effect, Injury: long-term effect, and Career-ending injury. Each level is described across four categories of descriptors: physical description, outcome (effect on running and daily life), psychological description, and management.

CONCLUSION: Unique to this study, we identified two categories of injury: lower level injuries, spanning from Discomfort to Non-responsive injury, and higher level injuries, spanning from Injury: short-term effect to Career-ending injury. Higher level injuries reflect research to date, specifically the consensus definition of injury [3], while lower level injuries expand on previous research [4]. However, we present novel findings in the identification of further lower level injuries. This continuum is useful for injury surveillance (for healthcare professionals (HCPs) and researchers) and for research investigating RRI risk factors. HCPs, and researchers must ensure they monitor the development of all levels of RRIs, across all categories of descriptors.

EFFECT OF A NONLINEAR EXERCISE PROGRAM THROUGH MHEALTH SYSTEM (ATOPE+) ON ISOKINETIC STRENGTH IN PATIENTS WITH BREAST CANCER UNDERGOING MEDICAL TREATMENTS

LOPEZ-GARZON, M., ALBERTI, P., POSTIGO-MARTIN, P., GONZÁLEZ-SANTOS, Á., GIL-GUTIÉRREZ, R., SALINAS-ASENSIO, M.M., RAMIREZ-PARADA, K., PUERTAS-MARTIN, M., GALIANO-CASTILLO, N., CANTARERO-VILLANUEVA, I.

UNIVERSITY OF GRANADA

INTRODUCTION: Knee strength is one of the indicators of oncological health(1). An important progress has been the initiation of physical exercise programs in patients who undergo chemotherapy (CT) or radiotherapy (RT), as they lead to strength deterioration. However, adherence may be low due to health fluctuations, for that reason, nonlinear exercise is being recommended for these patients. Thus, the aim of this work was to analyse the effect of a nonlinear exercise program through mHealth system on lower limb isokinetic performance in women with breast cancer undergoing medical treatment.

METHODS: A pre-post study was carried out. Newly diagnosed women with breast cancer were recruited from two Hospitals in Granada (Spain). After obtaining written informed consent, women were derived to receive CT or RT. The ATOPE program consisted of 18 sessions of multimodal physical exercise program, doses were prescribed based on heart rate variability and clinimetric assessments through daily assessments using the mHealth system ATOPE+(2). Strength and aerobic bouts oscillated between moderate and high intensity, progressing in velocity execution and/or number of repetitions and duration time, respectively. Increments of physical activity was encouraged from 10,000 up to 12,500 steps per day. Isokinetic strength was measured with HUMAC NORM at 60º/s, 180º/s and 300º/s at baseline and after the program. Two-way analysis of variance (ANOVA) was used.

RESULTS: Thirty-two women were included (52.31±9.62 years), 17 underwent CT and 15 RT. The ANOVA showed an intragroup effect in torque max isokinetic 60º/s extension $F(1,21)=53$, $p<0.01$, $\eta^2=0.716$; where the CT group reduced 49.20 N from baseline (from 109.10±10.27 to 59.90±5.85 N, $p<0.001$), as well as the RT group reduced 22.54 N from baseline (from 85.69±9.01 to 63.15±5.13 N, $p=0.002$). Additionally, a significative intragroup effect was found in 60º/s flexion $F(1,21)=9.62$, $p=0.005$, $\eta^2=0.314$; where an increase of 23.92 N was observed only in the RT group (from 62.39±5.49 to 86.31±7.02 N, $p<0.001$). Regarding 180º/s, a significative intragroup effect in torque max extension was found $F(1,21)=20.43$, $p<0.01$, $\eta^2=0.493$, that revealed a reduction of 24.78 N in the CT group (from 71.89±6.50 to 47.11±3.46 N, $p<0.001$). Finally, an effect in torque max isokinetic 300º/s extension $F(1,20)=5.39$, $p<0.031$, $\eta^2=0.212$ and a intragroup reduction of 12.22 N were found in the CT group (from 49 ±4.44 to 36.78±2.95, $p=0.004$).

CONCLUSION: Since patients with cancer normally show a CT and RT induced deterioration of strength, an increase but also the maintenance of strength is an important finding. A recent study found an isokinetic strength improvement in patients undergoing CT of 20.8 N, ES = 0.57 compared to the control group after the program(3). In our study, for ethical reasons, a control group was not used.

This work is funded by the European Social fund the Carlos III Health Institute (PI18/01840 and FI19/00230).

POLYCYSTIC OVARY SYNDROME DOES NOT ALTER RESTING CEREBRAL BLOOD FLOW

RICHARDS, C.T., GRIFFITHS, T.D., ALED REES, D., LORD, R.N.

CARDIFF METROPOLITAN UNIVERSITY

INTRODUCTION: Polycystic Ovary Syndrome (PCOS) is the most common endocrine condition, affecting up to 21% of women. PCOS is associated with cardiovascular risk factors such as hypertension, hyperandrogenism and elevated insulin resistance which lead to increased morbidity and mortality from cardiovascular disease. PCOS patients have altered white matter microstructure and reductions in cerebral volume, which may explain their diminished cognitive performance. However, despite differences in cerebral structure, the impact on cerebral blood flow and regulation has not been determined in these patients.

METHODS: Women diagnosed with PCOS via the Rotterdam criteria (Age: 34 years ± 7; BMI: 29.4 kg/m2 ± 6.1) (n = 7) and healthy age- and BMI-matched controls (Age: 30 years ± 4; BMI: 28.1 kg/m2 ± 4.7) (n = 6) were recruited. Baseline cerebrovascular function was assessed. Following a period of supine rest, end tidal carbon dioxide (ETCO2), mean arterial pressure (MAP) and mean arterial blood flow (Q) were measured. Longitudinal B-mode ultrasound images were collected through the right common carotid (CCA), internal carotid (ICA) and vertebral (VA) arteries using a 12MHz transducer and stored for offline analysis. Blood pressure was measured using finger plethysmography. Global cerebral blood flow (gCBF) was calculated by: 2 • (mean ICAQ + mean VAQ). Cerebrovascular conductance index (CVCi) was calculated locally as (⟦ICA⟧ _Q or ⟦VA⟧ _Q)/MAP. An independent groups t-test was utilised to determine differences in gCBF between groups , with significance set at $P < 0.05$.

RESULTS: Groups were matched for age (P=0.23) and BMI (P=0.67). There was no difference in ETCO2 (PCOS: 36.3 mmHg ± 3.9; CON: 35.4 ± 2.6)[P = 0.68], MAP (PCOS: 95.3 mmHg ± 13.5; CON:82.93 mmHg ± 15.3)[P = 0.14], CVCICA (PCOS: 2.03 ± 0.7; CON: 2.53 ± 0.6)[P = 0.20] and CVCVA (PCOS: 0.55 ± 0.24; CON: 0.80 ± 0.25)[P = 0.10]. gCBF (PCOS: 457 ml.min-1 ± 87.8; CON: 542 ml.min-1 ± 131.9) was similar between groups (P = 0.19).

CONCLUSION: Despite women with PCOS presenting with altered cerebral structure, gCBF remains similar to healthy, matched controls. MAP, and thus CVCi in both ICA and VA supplying the cerebrum are also similar. This may suggest that despite elevated cardiovascular risk, resting cerebrovascular function is maintained in the brain of women with PCOS. Therefore, further research is warranted to better understand the mechanisms at work, and ascertain the cause of the altered cerebral structure in PCOS.

OUTDOOR FITNESS COURT FUNCTIONALITY: ITS RELATIONSHIP TO CVH AND COMMUNITY ENGAGEMENT

VAUGHN, M., EXFORD, T.J.
KUTZTOWN UNIVERSITY OF PENNSYLVANIA AND THE UNIVERSITY OF NORTH CAROLINA GREENSBORO

INTRODUCTION: Cardiovascular disease (CVD) describes diseases of the heart or blood vessels. The four main types include coronary heart disease, stroke, peripheral arterial disease, and aortic disease. According to the World Health Organization Statistics (2022), heart disease is the leading cause of death for men, women, and people of most racial and ethnic groups. Heart disease accounts for 17.9 million deaths annually. Therefore, health initiatives must be established to combat the effect of CVD across the globe. Recent research indicated that health initiatives like exercise is medicine, lifestyle medicine, using wearable technology, outdoor activities/fitness gym, high intensity interval training (HIIT), and health and wellness coaching were effective strategies that can get people moving and lead to a reduction in CVD in society (Kercher et al., 2022). Due to the continued worldwide influence of the COVID-19 pandemic on our health and health outcomes, there is an increase demand for wearable technology and outdoor activities/fitness gym. Organizations like the National Fitness Campaign are poised to install over three thousand outdoor activities/fitness gym worldwide to build healthy communities and improve health outcomes for all. This study expands scholastic inquest into the instillation impact on cardiovascular health (CVH) and community engagement in a rural community. More specifically, the purpose of the research is two-fold: 1) to explore the National Fitness Campaign Outdoor Art Fitness Court/Gym impact on CVH in a rural Community and 2) to investigate the Keith Haring Art Fitness Court Instillation impact on community engagement and fitness in a rural community.

METHODS: The study employed a mixed method research design. Investigators utilized a convenient sampling technique to recruit participants 18 years and older. A sample size of one hundred participants was determined by effect size and Z-score with levels of significance for the test. IBM SPSS Statistics 27 was used to analyze an outdoor information Kiosk data, cardiovascular physical assessments, and the Life's Essential 8 survey. Descriptive analysis and constant comparison method are employed to analyze the SOPARC and audit trail data from two fitness challenges.

RESULTS: Preliminary research findings yield pragmatic implications on how practical initiatives can enhance community engagement and its sustainability. It indicates that the finding will help local government officials identify areas for CVH education and avenues to operationalized practical health initiatives to better serve communities.

CONCLUSION: After COVID-19, people desire more outside activities. So, the outdoors fitness courts/gyms have seen a significant upward trending trajectory. This provides a clear pathway for research and initiatives with pedagogical and technological advances, data sharing, and instillation of more outdoor fitness courts/gyms across the globe. More significantly, an individual CVH can improve with this approach.

IS PHYSICAL EXERCISE-INTERVENTION CAN BE VALUABLE THERAPY FOR COVID-19 ?

KWAK, Y.
DONG-EUI UNIV

INTRODUCTION: COVID-19 has become a pandemic and endemic affecting on physical health, physical conditioning, well-being, and mental health status. And moreover, It also brings about on the educational problem, economic, social networks, cultural, and psychological problems as well as physical health.

This kind of home confinement, social distancing and physical inactivity impacts on the many health disease such as obesity, diabetes mellitus, hypertension, hyperlipidemia, cardiovascular and mental health problem such as depression, sleep quality. Systemic review research reported that regular and

repeated (2-3 sessions/week) aerobic programs (cycling or walking with an intensity of 60-80% HR max, 20-60min/ session) increase physical and mental health as well as immune functions. This kind of physical activity increased immunological markers such as lymphocytes, leukocytes, neutrophils,

monocytes, IL-6 and even low graded inflammation. Therefore, the present research is to analyzed the impacts of tailorized exercise-interventions on physical and mental health problems of COVID-19 patients in the main text.

METHODS: For this research, PubMed database were evaluated from the January 2020 to September 2021 using predefined search terms 'COVID-19 pandemic' , exercise-intervention, and 'mental health'.

Using this references, we analyzed the connections between exercise-intervention and mental, physical health problems of COVID-19 pandemic patients.

RESULTS: One systemic review research reported that regular and repeated (2-3 sessions/week) aerobic programs (cycling or walking with an intensity of 60-80% HR max, 20-60min/ session) increase physical and mental health as well as immune functions. This kind of physical exercise increased immunological markers such as lymphocytes, leukocytes, neutrophils, monocytes, IL-6 and even low graded

inflammation. Therefore, enhanced immune functions appeared following the exercise-intervention especially to the disease and elderly people.

Especially, COVID-19 patients usually suffer from the symptoms of airway and pulmonary health Problems, therefore It should be prescribed as pulmonary rehabilitation such as posture, stretching, manual therapy, physical activity with breathing exercise.

Breathing exercise and respiratory support such as yoga, thoracic expansion exercises, airway clearance methods, breathing control and regular physical exercise will be helpful for physical health and mental health as well as immune responses.

CONCLUSION: Tailored multipronged exercise-intervention should be developed and applied to provide the existing mental challenges and enhance mental health of pandemic periods. Furthermore, the continuous epidemiological distribution of physical and mental health problems were heterogeneous among the general public. More scientifical interdisciplinary and intertribal studies about exercise- intervention on physical and mental health problems is urgently needed in this pandemic

periods.

EFFECTS OF IYENGAR YOGA ON FLEXIBILITY AND STRESS OF THAI STUDENTS: A CASE STUDY OF STUDENTS MAJORING IN SPORTS SCIENCE OF SILPAKORN UNIVERSITY

NHUSAWI, K., NEELAPAIJIT, N., CHANTASORN, N., KAESMAN, I., SUNGKHALERT, N., SATHITPAISANWONG, C.

SILPAKORN UNIVERSITY

INTRODUCTION: The recent outbreak of COVID-19 had a devastating effect on the physical, mental, emotional, and social health of Thais especially teenagers. Yoga has been associated with positive outcomes in physical performance and improvements in mental health [1]. Flexibility and stress has also been managed in teens using yoga [2]. The authors hypothesized that this approach would enhance flexibility and ameliorate COVID-19 stress symptoms in university students. The purpose of this research was to compare the effects of Iyengar yoga training on the flexibility and stress levels of Silpakorn University students.

METHODS: The sampled population comprises 15 male student volunteers in the Sports Science program at Silpakorn University. Participants had 60 minutes of Iyengar yoga sessions thrice (Monday, Wednesday, and Friday) weekly for 8 consecutive weeks. Prior to commencing the session, a Sit and Reach Test was conducted; this was also repeated after week 4 and week 8 of training. An 8-week self-assessment and stress evaluation was also performed during the study. Data analysis was conducted using Mean, Standard deviation, and One-Way ANOVA with Repeated Measure were estimated. A Bonferroni Post-Hoc Test was employed with an alpha level of .05 for all statistical tests.

RESULTS: 1. Pre-test flexibility training score was 10.00+7.5. Mean flexibility score increased to 11.30+7.14 and 13.10+7.04 at weeks 4 and 8 of training respective Pre-test mean stress effect score was 15.73+6.74; this score decreased to 12.40+6.12 and 11.00+5.90 at weeks 4 and 8, respectively.

2. The comparison between the results of flexibility and stress tests before the training and after weeks 4 and 8 of training was statistically significant ($p < 0.05$).

CONCLUSION: Iyengar yoga training has a favorable effect on increasing flexibility and reducing stress associated with university life.

ASSOCIATION OF SPORTS CLUB MEMBERSHIP WITH HEALTH LITERACY, HEALTH BEHAVIOURS, AND HEALTH STATUS AMONG JAPANESE UNIVERSITY STUDENTS

KITAMURA, H.1, FUJITSUKA, C.2

1 UNIVERSITY OF MARKETING AND DISTRIBUTION SCIENCES, 2 KUMAMOTO GAKUEN UNIVERSTITY

INTRODUCTION: Health literacy is associated with individual health status and is a key social determinant of health. Previous research has shown that adolescents who participated in sports club activities have higher levels of health literacy. However, the relationship between health literacy, health behaviors, health status, and sports club membership among Japanese university students has not been well studied. The aim of this study was to examine the mediating effect of sports club membership on the association between health literacy, health behaviors and health status.

METHODS: An anonymous voluntary online survey was used to collect data on 517 participants from two Japanese universities in July 2022. Data were collected on the following participant characteristics: age, residence, number of commute days, number of friends, sports club membership status, health behaviours, self-rated health, and general trust. Participants were asked about 10 health behaviours: exercise/sports activity, diets, sleep, smoking, drinking, stress coping, tooth brushing, weight management, health check-ups, and health information. We measured health literacy using the short version of the European Health Literacy Survey Questionnaire for Japanese (J-HLS-EU-Q16). The health literacy score was calculated according to the recommendations of the European Health Literacy Project. The chi-square test was used to evaluate for statistical differences between sports club membership and participant characteristics, health behaviours, and health literacy score. All statistical analyses were performed using IBM SPSS 26.0.

RESULTS: Participant's average age was 19.39 ± 1.19 years, and 203 participants (39.3%) were female. 398 participants (77.0%) lived with their families, while 247 (47.8%) commuted to university five days a week. 128 participants (24.7%) were sports club members. The average health literacy score was 36.5 ± 6.4. Health literacy levels significantly differed by sex, commute days, sports club membership, self-rated health, and general trust. Sports club membership was significantly associated with sex, number of friends, self-rated health, several health behaviours (exercise/sports activity, diets, and weight management), and health literacy score.

CONCLUSION: These results suggest that Japanese university students who were sports club members had higher health literacy levels and engaged in healthier behaviours than non-members. Further studies are needed to confirm the importance of health literacy in promoting the health of young people.

LONG-TERM TAI CHI TRAINING IMPROVED COGNITIVE PERFORMANCE: A CROSS-SECTIONAL STUDY

HUI, S.S.C.1, WAN, J.H.P.1, CHIN, E.C.Y.1, SHUM, Y.H.2, TSE, C.Y.3, HSIAO, J.H.W.4, HU, X.4, SIU, P.M.F.5, KRAMER, A.6
1DEPARTMENT OF SPORTS SCIENCE AND PHYSICAL EDUCATION, THE CHINESE UNIVERSITY OF HONG KONG, HONG KONG. 2BERLIN SCHOOL OF MIND AND BRAIN, HUMBOLDT UNIVERSITY, GERMANY. 3DEPARTMENT OF SOCIAL AND BEHAVIO

INTRODUCTION: The dose-response of long-term Tai Chi training effect on cognitive function is largely unclear. The purpose of this study is to compare the effectiveness of three Tai Chi proficiency levels (i.e., ≤ 1 year; ≥ 10-30 years; > 30 years) on executive function and long-term memory.

METHODS: A total of 39 age-matched healthy Tai Chi practitioners were recruited in this study. The practitioners were categorized into three groups based on their years of experience in Tai Chi training: 1) Novice (≤ 1 year, n=13, age: 68.4±3.4 yrs); 2) Master (≥ 10-30 years, n=15, age: 66.5±7.5 yrs); and 3) Top Master (≥ 30 years, n=11, age: 67.0±4.7 yrs). All practitioners practice Yang-style Tai Chi in their usual training. The executive function and long-term memory were assessed by the completion time in the Trail Making Test (TMT) (i.e., Part A score, Part B score, Part B-A score, Part B/A; lower TMT score indicates better executive function) and Chinese-version Rey Auditory Verbal Learning Test (i.e., the number of recalled words after 30 minutes), respectively.

RESULTS: Significant group effects were detected on the TMT Part A score (p=0.023), the TMT Part B score (p=0.003), and TMT B-A different score (p=0.024). The post-hoc analysis indicated that the Top Master demonstrated a significantly lower TMT Part A score (p=0.032), TMT Part B score (p=0.002), and TMT Part B-A score (p=0.034) compared to the Novice. The Master group demonstrates lower scores in TMT Part A (p=0.092), TMT Part B (p=0.078), and TMT Part B-A (p=0.093) than the Novice. No significant differences were observed in all parameters from the Chinese-version Rey Auditory Verbal Learning Test.

CONCLUSION: The present study demonstrated that prolonged Tai Chi training may lead to better improvement in executive function among older-aged adults.

PREVENTIVE EFFECT OF EXERCISE ON DEPRESSION-LIKE BEHAVIOR VIA DECREASING HIPPOCAMPAL TSPO

WATANABE, C., OYANAGI, E., HAMADA, H., KAWASHIMA, M., YAMAGATA, T., AOKI, T., YANO, H.
KAWASAKI UNIVERSITY OF MEDICAL WELFARE

Introduction

Depression and other mental disorders have occurred in about 322 million people worldwide.

Recent studies have reported that Translocator protein 18 kDa (TSPO) is involved in the depression as well as inflammatory cytokines and immune related molecules in the brain. Additionally, there are many studies advocating the positive effects of exercise on mental health. However, the involvement of TSPO in the effect of exercise on depression remains unclear. In this study, we examined whether or not TSPO is involved in the depression preventive effects of exercise.

Methods

Four-week-old male C57BL/6 mice (n=40) were treated with sedentary control (Ctrl), socially defeated stress for 10 days (SDS), SDS after the wheel running for 10 weeks (SW) and administration of PK11195, an antagonist against TSPO, during SW (SW-P). As SDS, mice were treated to physical interactions with ICR mice, which are aggressive effector mice, for 5 min once per day and then the mice were housed on the opposite side of the stress cage over the subsequent 24-h period daily for 10 days. After the experimental period, the social interaction, forced swimming and sucrose preference tests were performed to evaluate the depression-like behavior in mice. The protein expression of TSPO was measured by western blotting.

Results

Although the thymus gland weight in SDS group was significantly smaller than that in Ctrl group ($p<0.05$), this SDS-induced atrophy was attenuated by wheel running ($p<0.05$). Additionally, social score in SDS group tended to be lowered, compared with that in Ctrl group, and was slightly improved by wheel running. We observed a decrease in the protein level of TSPO in hippocampus in SW group compared with Ctrl and SDS groups. Moreover, the TSPO expression was similar between SW and SW-P.

Conclusion

Wheel running may have a preventive effect on depression-like behavior with a decrease in hippocampal TSPO.

THE EFFECTS OF AN EXERCISE TRAINING ON CORTISOL REACTIVITY PREADOLESCENT CHILDREN

AKKO, D.P., MAZZOLI, E., GRONWALD, T., BUDDE, H.

UNIVERSITY OF HAGEN

INTRODUCTION: Over the past years, exercise training has been suggested as a significant moderator that increases neurogenesis and improves neuroplasticity as well as overall mental health. Studies so far suggest that acute exercises as well as exercise training have an impact on the Steroid Hormones, which modulate multiple physiological processes in the human body. Depending on the intensity, an acute bout of exercises was found to affect the Hypothalamic-Pituitary-Adrenal (HPA)-axis responsiveness. As an indicator for HPA-activity, the current study investigates the acute effect of exercise on salivary Cortisol reactivity before and after a 10week exercise training.

METHODS: 71 children at the age of M = 9.4 years (SD = 0.6) were assigned to an interventional (n = 50) and a control group (CON, n = 21). While the CON participated in assisted homework sessions, the interventional group was either joining an aerobic or a coordinative exercise training with a moderate intensity of 64%-76% HRmax. All programs were applied 3x/week for a total of 10 weeks. Salivary cortisol levels were raised immediately, 15 minutes and 30 minutes after an acute exercise session of 45 minutes. As an indicator for Cortisol reactivity the Area Under the Curve with respect to the Ground (AUCG) was calculated. This procedure was applied before (t1) and after (t2) the 10week exercise training program.

RESULTS: The 2x2 ANOVA Model revealed a main effect of time ($F(1,69) = 5.76$ $p = .010$, $\eta2 = 0.08$) and group ($F(1,69) = 2.97$, $p = .045$, $\eta2 = .04$) regarding cortisol AUCG. The time*group interaction was not significant ($p = >.05$). Using single dependent t-Tests a significant increase in the interventional group was found ($p = .013$, $d = 0.36$), while no significant changes in the CON were observed ($p > .05$).

CONCLUSION: Therefore, we argue that a 10week exercise training might increase acute Cortisol reactivity in preadolescent children.

EXPLORING THE CHANGE PATTERNS OF SPEECH FEATURES UNDER DIFFERENT EXERCISE STATES

MA, R.S., SUM, R.K.W.

THE CHINESE UNIVERSITY OF HONG KONG

INTRODUCTION: This study aimed to explore the variation in physiological vocal parameters under different exercise intensities.

METHODS: All participants were recruited from the Chinese University of Hong Kong using a cross-sectional study design with convenience sampling method. A total of 31 participants were recruited for the present study. Participants were asked to wear a heart rate detector to complete three different exercises and then read aloud a passage at the end of each exercise. The fundamental frequencies (F0) were extracted from the speech data, one-way Repeated Measures Analysis of Variance (RM-ANOVA) was used to investigate the difference of speech features in each exercise state. Pearson's product-moment correlation and simple linear regression was carried out to examine the relationship among each feature.

RESULTS: The RM-ANOVA had statistically significant differences between the means of the speech duration($F (3, 90) = 7.89$, $p = .001$, $\eta2 = .21$), F0 ($F (3, 90) = 34.32$, $p < .001$, $\eta2 = .53$), F0 range in 25% and 75% ($F (3, 90) = 10.68$, $p < .001$, $\eta2 = .26$), pause times ($F (3, 90) = 60.21$, $p < .001$, $\eta2 = .67$) and pause duration ($F (3, 90) = 63.27$, $p < .001$, $\eta2 = .68$). F0 and its range in 25% and 75% under vigorous intensity exercise were significantly different from the other states. The duration of speech throughout the paragraph also increased as the exercise intensity rose. The number and duration of pauses were more discriminative across exercise states. Compared to F0, which differs only under vigorous intensity exercise, features of pause also allowed to separate moderate intensity from resting states.We tested the correlation between heart rate and speech features. The correlations were significant for most of groups. And most of the regression equations had R2 above 20%, which means at least 20% of the variance in our speech data can be explained by the variable of heart rate. Among these equations, heart rate of males predicted three features: 1) F0 mean = 110.90 + .16 * heart rate; 2) Pause times = 4.25 + .05 * heart rate; 3) Pause duration = 1.26 + .04 * heart rate. For females, heart rate predicted four features: 1) F0 mean = 164.13 + .42 * heart rate; 2) Range = 26.77 + .12 * heart rate; 3) Pause times = 4.43 + .04 *heart rate; 4) Pause duration = .57 + .04 * heart rate.

CONCLUSION: This study explored the change patterns of speech features under different exercise states. The speech features explored in this study were handcraft features that provide a reliable choice of parameters for further exploration of the association between speech features and exercise states.

INVESTIGATING KEY DETERMINANTS OF LUNG FUNCTION TRAJECTORIES IN CHILDREN AND YOUNG PEOPLE, AND THE INFLUENCE OF PHYSICAL ACTIVITY ON THESE VALUES

JORDAN, K.

SWANSEA UNIVERSITY

INTRODUCTION: Respiratory disease is considered a major threat to morbidity and mortality. Whilst the manifestation of lung disease usually occurs in adulthood, the underlying disease processes may begin much earlier in childhood. In order to identify the onset of disease with more certainty, a better understanding of both the trajectory of lung function, and the influencing lifestyle factors, such as physical activity (PA) are needed. Whilst the development of the lung is, at least in part, subject to perinatal factors, a variety of different factors and exposures have been shown to influence, and potentially maximize, function. This study sought to better understand the developmental trajectories of lung function and the complex relationship PA may have on lung function in childhood.

METHODS: Using latent growth curve analysis and structural equation modelling, the developmental trajectories over three time-points spanning x years of forced vital capacity (FVC) and forced expiratory volume in 1 second (FEV1) were investigated. Separate multi-nomial logistic regression models for boys (n=398; x ± y yrs) and girls (n=372; x ± y yrs) were then used to determine whether MVPA influenced FEV1 and FVC trajectories, and whether this differed by sex when controlling for height, body mass and ethnicity.

RESULTS: Whilst three distinct trajectories were identified for males (low=30.9%; medium=57.9%; high=11.2%), four trajectories were identified in girls for FEV1 (low=6.3%; medium=43.6%; high=38.9%; very high=11.2%). Similarly, for FVC, three distinct classes were identified for boys compared to four trajectories in girls. The distributions indicated that trajectory groups for FEV1 differed significantly on the proportion of male and female students (X^2=12.816, p=0.002) with distributions in Group 2 higher for females (40.9%) than males (29.4%), whereas the distributions within Group 1 and Group 3 was higher for males (14.8% and 55.8% respectively) than females (9.7% and 49.5%). For FVC, the distribution between trajectory groups differed significantly according to sex (X^2=42.500, p<0.001), with greater proportion of boys in groups 2 and 3 higher (61.3% and 13.1%, respectively) than girls (48.4% and 5.1% respectively), whilst group 1 was higher for girls (46.58%) than boys (25.6 %). When using PA as a predictor of trajectory class, regression analysis did not reveal any significant relationships.

CONCLUSION: These findings highlight the, often overlooked, but important role that sex plays in determining lung function in youth. Given that little is known as to why females suffering from respiratory disease often experience poorer disease control and outcomes, these findings have important implications in beginning to understand this discrepancy. Further research is warranted to investigate this disparity between the sexes and the role that PA may play towards this.

24-HOUR MOVEMENT BEHAVIORS AND EXECUTIVE FUNCTIONS IN PRESCHOOLERS: A COMPOSITIONAL AND ISOTEMPORAL REALLOCATION ANALYSIS

LAU, W.1, SONG, H.1, WANG, J.2, YU, R.1, ZHEN, S.3

1. HONG KONG BAPTIST UNIVERSITY; 2. CHINA INSTITUTE OF SPORT SCIENCE; 3. CITY UNIVERSITY OF HONG KONG

INTRODUCTION: This study explored the association between 24-hour movement behaviors and executive function (EF) in preschooers.

METHODS: This cross-sectional study was carried out with 447 preschoolers (242 boys, means age= 4.4 ± 0.9 years). Physical activity (PA) and sedentary behavior (SB) were assessed using an accelerometer for seven consecutive days. Sleep time was obtained through the parent-report questionnaire. Components of EF (cognitive flexibility, inhibitory control, and working memory) were assessed using the computerized behavioral tasks. To verify the association between 24-hour movement behaviors and EF, the compositional data analysis was used, and for the time reallocation, the compositional isotemporal substitution analysis was used.

RESULTS: The daily composition, adjusted for age, gender, and BMI, was significantly associated with inhibitory control (p<0.001; r2= 0.12), and working memory (p<0.001; r2= 0.30). The addition of MVPA at the expense of SB and LPA, LPA at the cost of sleep, were associated with significant inhibitory control improvements. The reallocation between MVPA and LPA yielded significant association with working memory. The impact of MVPA replacing LPA is stronger than MVPA replacing SB on inhibition control.

CONCLUSION: These findings highlight the importance of maintaining or increasing MVPA in EF development in preschoolers.

NO ADDITIONAL EFFECT OF HYPOXIA OR PLACEBO OVER NORMOXIA DURING A 3- WEEKS REPEATED-SPRINT TRAINING: A DOUBLE-BLIND STUDY

GUTKNECHT, A.P.1, GONZALEZ-FIGUERES, M.1, BELDA, G.2, BILLAUD, J.B.2, GRESSE, A.2, PERREY, S.1, FAVIER, F.B.1

1 UNIVERSITY OF MONTPELLIER 2 SEMAXONE

INTRODUCTION: Repeated-sprint training in hypoxia (RSH) seems to be particularly effective in increasing anaerobic performance of athletes in various sports. However, belief in the positive effects of altitude is widespread among coaches and athletes, raising the issue of a putative placebo effect of such training. The purpose of this study was to determine the respective effects of normobaric hypoxia and placebo combined to a repeated-sprint training.

METHODS: Thirty moderately trained participants [age (mean ± SD) 20.7 ± 3.1 years] were randomly allocated to 3 groups: normoxia (RSN; inspired oxygen fraction (FiO2) 20.9%) placebo (RSN-P; FiO2 20.9%) or hypoxia (RSH; FiO2 14.5%). Participants from the RSH and RSN-P groups were connected to a hypoxic generator during training and were told they trained under simulated altitude (between 2500 and 3500 m). Participants from the RSN group knew they were training at sea level. Training consisted in six cycling sessions comprising three sets of 8 x 6-s sprint with 24-s over three weeks. Power outputs were measured during a Wingate (30 s) and a repeated-sprint ability test (RSA; 10 x 6-s sprint with 24-s recovery) before, one and two weeks after training.

RESULTS: None of the participants in the RSN-P and RSH groups estimated being in normoxia during training, and mean estimated altitude was not different between groups (2500 ± 445 and 2605 ± 425 m in RSN-P and RSH, p = 0.60 respectively). As expected, the RSH group was the only one with SpO2 values that differed from those of the RSN group (85.5 ± 2.6%, 96 ± 1.4%, and 95.8 ± 0.6%; p < 0.001 for RSH, RSN-P, and RSN, respectively).

The relative intensity during training (power output normalized by the mean power output sustained during the pre-RSA test) was not different between the 3 groups (91 ± 3.9, 91.2 ± 6.28, and 87.2 ± 3.7%; p = 0.14 for RSH, RSN-P, and RSN, respectively), whereas the subjective rating of perceived exertion was higher in the RSH group (15.3 ± 0.9, 14.3± 0.8, and 14.4 ± 1; p = 0.04 for RSH, RSN-P, and RSN, respectively). Mean and peak power outputs on RSA and Wingate tests were significantly increased after training in all groups. However, no group has progressed more than another.

Regarding the ability of participants to achieve a maximum number of sprints more powerful than 85% of the best performance of the RSA pre-test, no evolution exists (p = 0.91).

CONCLUSION: These data show that repeated-sprint training is effective in improving anaerobic performance and that hypoxia exposure during training did not provide additional benefit.

EXCLUSIVE, ADDITIVE AND INTERACTIVE EFFECTS OF COLD AND HYPOXIA ON MAXIMAL ENDURANCE EXERCISE AND LACTATE THRESHOLD PARAMETERS.

CALLOVINI, A.1,2, FORNASIERO, A.1,2, SAVOLDELLI, A.1,2, DECET, M.1,2, SKAFIDAS, S.1, PELLEGRINI, B.1,2, BORTOLAN, L.1,2, SCHENA, F.1,2

CERISM - UNIVERSITY OF VERONA

INTRODUCTION: Endurance athletes often train and compete at high altitude and/or within extreme cold conditions[1]. Exclusive effect of hypoxia and cold has been widely studied, but to what extent combined stressors exposure affects endurance performance[2] and throughout which mechanism (additive or interactive)[3] is unknown. The aim of this study was to evaluate the influence of combined acute normobaric hypoxia and cold on maximal and lactate threshold parameters.

METHODS: 14 trained male subjects (age:27±3, VO2max:64±5 mL/kg/min) randomly performed a maximal incremental test on a motorized treadmill (slope:25%) under four environmental conditions: Normothermic Normoxia (N:18°C,20.9%FiO2), Normothermic Hypoxia (H;18°C,13.5%FiO2), Cold Normoxia(C:-20°C,20.9%FiO2) and Cold Hypoxia(CH:-20°C,13.5%FiO2). Workload (WL), Heart Rate (HR), RPE and ventilation (Ve) at maximal and lactate threshold (LT) intensities[4] were determined.

RESULTS: At maximal intensity, WL and HR were reduced in C (-2.3% and -3.2% respectively, all p<0.001) and H (-18.0% and -5.0% respectively, all p<0.001) compared to N, with no interactive (p>0.20) but additive effect in CH (-21.5% and -7.7% for WL and HR). Relative additive effect was seen also on maximal Ve, which decreased by 14.6% in C (p<0.001), 6.9% in H (p=0.017) and 16.6% in CH (interaction effect p=0.12). Maximal RPE was not affected by the environmental condition. At LT intensity, WL and HR were reduced in C (-3.5% and -2.8% respectively, all p<0.013) and H (-21.7% and -3.8% respectively, all p<0.004) compared to N, with no interactive (p=0.81 and p=0.62 for WL and HR) but additive effect in CH (-24.6% and -5.7%, respectively). Exclusive effects of hypoxia were noted on HR expressed as % of maximal HR (p<0.001), and on RPE (p<0.001) associated with LT intensity. An interactive effect (p=0.007) of the two stressors combined was noted at LT intensity on Ve, which resulted lower in CH (86±15 L/min) if compared to N (97±15 L/min), C (102±13 L/min) and H (94±15 L/min).

CONCLUSION: The combination of cold and hypoxia exerts additive rather than interactive effects, decreasing LT and maximal exercise workload and heart rate to an extent that is equal to the sum of the two stimuli alone. However, both exclusive effects of hypoxia and interactive effects of cold and hypoxia were found on the investigated physiological and perceptual variables. This highlights the need for trainers to take into account environmental stressor effect on endurance performance for optimal exercise intensity prescription, pacing strategy decision and training load monitoring in athletes training/competing in hypoxic and cold environments.

EFFECTS OF ALTITUDE OF RESIDENCE ON HAEMATOLOGICAL CHARACTERISTICS AND PERFORMANCE IN YOUTH MALE COLOMBIAN CYCLISTS.

GARZON, M.1, MANCERA, E.2, COMTOIS, A.1, MILLET, G.3

1. UNIVERSITY OF QUEBEC IN MONTREAL, MONTREAL, QUEBEC, CANADA; 2. NATIONAL UNIVERSITY OF COLOMBIA; 3. INSTITUTE OF SPORT SCIENCES, UNIVERSITY OF LAUSANNE, LAUSANNE, SWITZERLAND.

INTRODUCTION: To compare physiological and haematological characteristics and performance variables between youth and junior cyclists (YC and JC, respectively) born and trained at high altitude (HA, >2500 m) vs sea-level (SL, <1000 m).

METHODS: 51 YC (15-16 years; n=31) and JC (17-18 years; n=20) born and trained at HA and SL participated in the study. Hemoglobin mass (Hbmass, g.kg-1), blood (BV, L) and plasma volume (PV, L) were determined by CO rebreathing and hematocrit (Hct, %) by capillary blood drop sample. Maximal oxygen consumption (VO2max, mL.kg-1.min-1) was estimated on a stationary bicycle. Training experience (TE, month); Weekly training volume in hours (WTV, h), daily training volume (DTV, min); weekly sessions (FTW) and peak power output (PPO, W.kg-1) were also analysed.

RESULTS: All training parameters (TE, WTV, DTV and FTW) were not different between HA and SL cyclists in both YC and JC groups.

However, in YC, HA residents had higher values in VO2max (65.5±4.6 vs 60.7±5.0 mL.kg-1.min-1, p=0.014); Hct (47.5±2.2 vs 45.7±1.8%, p=0.023); [Hb] (16.2±1.0 vs 15.5±0.7 g.dL-1; p=0.027); Hbmass (Hbmass, 15.1±1 vs 13.6±1.3 g.kg-1, p=0.002) and PPO (6.4±0.8 vs 5.8±0.6 W.kg-1, p=0.021). Similarly, in JC, values of VO2max (67.4±3.1 vs 61.1±5.6 mL.kg-1.min-1, p=0.008); Hct (49.5±1.6 vs 45.1±2.3%, p<0.001) and [Hb] (16.9±0.6 vs 15.1±1.0 g.dL-1, p=0.0001) were higher in HA than SL cyclists. However, no differences were found between these groups for Hbmass, (14.8±0.9 vs 14.2±1.3 g.kg-1, p=0.221), BV (5.6±0.7 vs 6.3±1.1 L, p=0.079) and PPO (6.2±0.4 vs 5.8±0.5 W.kg-1, p=0.118). Of interest, in the JC group, PV was lower (3.1± 0.4 vs 3.8±0.8 L, p=0.021) in native HA residents than in native SL residents, suggesting an altitude-induced hemoconcentration.

CONCLUSION: Although the training loads were not different between native residents of HA and SL, there were significant differences in the hematological variables, indicating the effect of birth and residence at altitude. In YC, these hematological advantages translated to higher PPO. The present study confirms that altitude of residence could denote an advantage for high-performance road cyclists, as already suggested (Garzon et al., 2022; Mateo-March et al., 2022).

THE ACUTE EFFECTS OF MODERATE EXERCISE IN HYPOXIA ON PHYSIOLOGICAL RESPONSES AND MUSCLE RECOVERY IN FEMALES

WELLAUER, V.

UNIVERSITY OF APPLIED SCIENCES AND ARTS OF SOUTHERN SWITZERLAND

INTRODUCTION: In the last decades, normobaric hypoxia (HYP) has increasingly gained attention in the field of sports science. However, there is still relatively little evidence available on HYP-induced performance enhancement, especially in the female population [1]. Therefore, this trial aimed to investigate the effects of moderate exercise, performed in HYP and normobaric normoxia (CON), on physiological responses and muscle recovery in females.

METHODS: Twenty recreational active females (23.3±2.3 years) were assigned to HYP (FiO2:12%) or CON (FiO2: 21%) using block randomization. One week after baseline measurements (BL), both groups performed a moderate muscle-damaging exercise protocol (5 x 20 drop jumps). Physiological makers (knee extensor muscle oxygen saturation [SmO2], capillary oxygen saturation [SpO2], heart rate [HR], core temperature (Tcore), local skin temperature of the anterior thigh [Tskin]), ratings of perceived exertion (RPE), and dyspnea (DYS) were assessed at BL, and after each exercise set (ES). Muscle recovery was evaluated by taking venous blood samples (for assessing CK, CRP, and blood sedimentation rate), investigating muscle swelling of the quadriceps femoris muscle, delayed onset of muscle soreness, counter-movement jumps, and maximal voluntary isometric contraction of the knee extensor muscles, at BL, 24-, 48- and 72-hrs post-exercise.

RESULTS: SpO2 was significantly lower in HYP compared to CON throughout the entire exercise task (ES1 to ES5: all p<0.001). In HYP, values remained also lower at the end of ES1 to ES5 compared to BL (all p<0.001), whereas there was no difference compared to BL values in CON. In SmO2, a trend towards lower values in HYP compared to CON was detected at ES3 (p=0.06) and ES4 (p=0.06), which reached significance at ES5 (p=0.03). Compared to BL, SmO2 values decreased significantly in HYP at ES2 (p=0.02) and ES3 (p=0.01). For SmO2, there were no within-group differences observed in CON. No physiological difference between HYP and CON were observed in HR, Tcore, Tskin, RPE and DYS ratings during the exercise task (all p>0.05). Likewise, for all muscle recovery markers, no differences between HYP and CON were found throughout the 72-hrs follow-up period (all p>0.05).

CONCLUSION: This study shows that moderate exercise under HYP leads primarily to reduced capillary- and muscle oxygenation in healthy females, compared to moderate exercise under normobaric normoxia. The response from recovery-, inflammatory- and subjective parameters are comparable to moderate exercise in normoxia. These findings support the idea that hypoxia-induced training adaptations are primarily caused by reduced oxygen availability and tissue oxygenation levels.

THE EFFECTS OF THREE WEEKS INTERMITTENT HYPOXIC THERAPY ON MITOCHONDRIAL FUNCTION: A PILOT STUDY

HOHENAUER, E., BIANCHI, G., CLIJSEN, R.

UNIVERSITY OF APPLIED SCIENCES AND ARTS OF SOUTHERN SWITZERLAND

INTRODUCTION: Normobaric intermittent hypoxia (NIH) therapy is a method, where repeated episodes of reduced FiO2 can be used for therapeutic purposes. Mitochondrial functioning is fundamental for human life due to its importance in energy production, besides other important roles. Taking several factors into account, the bioenergetic health index (BHI) was developed to evaluate mitochondrial functioning [1]. Although the literature in this field is growing, there is a lack of studies, investigating the effects of NIH on the BHI. Therefore, this pilot-study aimed to investigate the effects of a three-week lasting NIH therapy on mitochondrial functioning in healthy participants.

METHODS: Six healthy volunteers (n= 4 females, n= 2 males, 26.8±2.2 years, 72.7±14.1kg, 171.3±9.0cm) underwent 9 sessions of passive NIH for a duration of 3 weeks. The volunteers were seated and inhaled hypoxic air from an altitude generator (Everest Summit II, Hyoxico, Bickenbach, Germany) using a face mask. Capillary oxygenation saturation (SpO2) was measured using a pulse oximeter (Nonin 7500, Amsterdam, Netherlands) on the right index finger. Each session lasted 45 minutes and consisted of 10±0.6 hypoxic periods, where the participants SpO2 was reduced to 80-85% for an interval duration of 2 min. After the hypoxic interval, reoxygenation of SpO2 values to baseline was followed by the next hypoxic interval. At baseline and after three weeks of NIH, a venous blood sample was taken to determine the bioenergetic health index (BHI).

RESULTS: The BHI (mean difference: +0.09±0.03) of the volunteers showed a trend (p=0.06) for enhanced mitochondrial functioning after the three week lasting therapy. Mitochondrial ATP production (mean difference: +0.88±0.83%; p=0.03), and non-mitochondrial O2 consumption (mean difference: +1.32±0.16 pmolO2·min-1; p=0.03) both increased. The mitochondrial proton leak significantly decreased (mean difference: -0.87±0.83%; p=0.03) after the NIH therapy. The results demonstrated a tendency towards increased basal mitochondrial respiration (mean difference: +2.72±1.01 pmolO2·min-1; p=0.06), maximum mitochondrial O2 consumption (mean difference: +32.9±16.0%; p=0.06) and ATP reserve capacity (mean difference: +3.0±0.8%; p=0.06).

CONCLUSION: In conclusion, the preliminary results of this study show promising effects of NIH on the mitochondrial level with an overall borderline to significant BHI. The inner mitochondrial membrane is less permeable to protons, which return from the intermembrane space back into the matrix and are therefore available for ATP synthesis. The reduced proton leak after NIH can therefore explain the increase in mitochondrial ATP-production and ATP reserve capacity in our study. Future research should investigate further investigate NIH in a patient set-up and using a larger sample size.

REPEATED-SPRINT TRAINING IN HYPOXIA INDUCED BY HYPOVENTILATION AT LOW LUNG VOLUME: A META-ANALYSIS

PRECART, C.1,2, BOUTEN, J.2, WOORONS, X.3, BROCHERIE, F.2

1 THE UNIVERSITY OF PARIS CITÉ, FRANCE. 2 INSEP, PARIS, FRANCE. 3 UNIVERSITY OF LILLE, FRANCE.

INTRODUCTION: Repeated-sprint training in hypoxia (RSH) is a popular and effective method to improve physical performance (Brocherie et al., 2017). However, it requires hypoxic chambers, tents or hypoxic simulators. RSH induced by voluntary hypoventilation at low lung volume (RSH-VHL) is a recent method which can provide a low-cost alternative to RSH (Woorons et al., 2019). This method requires athletes to perform repeated-sprint efforts while holding their breath at the end of expiration, provoking systemic hypoxia as well as hypercapnia. The aim of this study was therefore to review the scientific literature and perform a meta-analysis on the effects of RSH-VHL vs. similar training with normal breathing (RSN) on physical performance.

METHODS: The PubMed/MEDLINE, SportDiscus®, ProQuest, and Web of Science online databases were examined for articles published up to February 2023 which evaluated changes in physical performance following RSH-VHL and RSN. The meta-analysis was conducted to determine the standardized mean difference (SMD) between the effects of RSH-VHL vs. RSN on repeated-sprint ability (RSA) related variables: best and mean performance (velocity or power output), sprint decrement score (Sdec), maximal blood lactate concentration ([Lamax]), single-sprint reference (Ref) and maximal oxygen consumption (VO2max).

RESULTS: After screening, 6 studies were considered for this meta-analysis, including a total of 127 individuals (mean age 21.2 ± 7 years, 115 males). These studies included 6-10 training sessions over 2-5 weeks. The training protocols consisted in 3 ± 1 sets of 9 ± 4 repetitions of 7 ± 1 s sprint with 22 ± 3 s intra-set recovery and 6 ± 6 min inter-set rest. Average recorded oxygen saturation (SpO2) for sprints in RSH-VHL was 89.4 ± 2.7 %. Maximal (SMD = 0.37, P = 0.04; small to moderate effect) and mean performance (SMD = 0.49, P = 0.01; small to moderate effect), as well as Sdec (SMD = 0.58, P < 0.01;

moderate to large effect) were significantly enhanced with RSH-VHL vs. RSN. The increase in [La]max following RSA in RSH-VHL compared to RSN was not significant (SMD = 0.32, P = 0.1; small to moderate effect). No significant effect was observed for RSH-VHL Ref (SMD = -0.14, P = 0.51) and VO2max (SMD = 0.54, P=0.11).

CONCLUSION: The present meta-analysis indicates that repeated-sprint training in hypoxia induced by hypoventilation at low lung volume provides putative gains in repeated-sprint maximal and mean velocity and fatigue resistance (sprint decrement score) than similar training with normal breathing. Whether this method induces similar or additional benefits compared to repeated-sprint training in hypoxia – demonstrated to induce higher hypoxic stress (Imai et al., 2022) but without hypercapnic stimulus – remains to be elucidated.

EFFECT OF ENDURANCE EXERCISE IN HYPOXIA ON SYMPATHETIC AND PARASYMPATHETIC NERVOUS ACTIVITIES DURING NIGHT

KOBAYASHI, M., KASAHARA, N., IMAI, A., GOTO, K.

RITSUMEIKAN UNIVERSITY

INTRODUCTION: Exercise under hypoxic condition has been previously shown to cause health benefits in various types of populations. In addition, endurance training in hypoxia is expected to reduce arterial stiffness, body fat mass compared to the same training in normoxia. Endurance exercise in hypoxia promotes sympathetic nervous activity during exercise and 1 h after exercise, but the time course changes in sympathetic nervous activity during night following the exercise in hypoxia remain unclear. The aim of the present study was to compare time-course changes in sympathetic and parasympathetic nervous activities during night following a single session of endurance exercise under either normoxic or hypoxic conditions.

METHODS: Ten young men (20.5±0.2 years) were recruited for the study. All of them carried out three trials on different days: (1) pedaling exercise in normoxia (FiO2: 20.9%; NOR), (2) pedaling exercise in hypoxia (FiO2: 14.5%; HYP), and (3) rest in normoxia (REST). Each trial was separated at least one week, with randomized orders. The exercise consisted of 60 min of pedaling exercise at 60% of maximal oxygen uptake (70 rpm), and the exercises in HYP and NOR trials were started at 17:00. During exercise, heart rate (HR), rating of perceived exertion (RPE) and arterial oxygen saturation (SpO2) were determined. In REST trial, the subjects rested for 60 min and HR, RPE, and SpO2 were monitored. Also, HR variability was continuously monitored until next morning (17:00-7:00) to calculate the power in the high frequency (HF), and the ratio of low frequency (LF) and HF (LF/HF) using a wearable HR sensor. On the following morning, the scores of fatigue, sleepiness, vitality, and quality of sleep were measured by visual analog scale (VAS).

RESULTS: During exercise, HR showed significantly higher value in HYP than in NOR ($p<0.001$). In addition, SpO2 was significantly lower in HYP(83.4±0.5%) than in NOR (96.8±0.3%, $p<0.001$). During 1-3 h after completing exercise (19:00-22:00), LF/HF showed tendency of high values in both NOR and HYP compared to REST. During whole night sleep (23:00-7:00), averaged LF/HF did not differ significantly among the trials ($p>0.05$). However, HYP showed significantly lower HF compared to REST ($p=0.015$), whereas no significant difference was observed between HYP and NOR($p>0.05$). Moreover, vitality showed lower score in HYP than REST on the following morning($p=0.02$).

CONCLUSION: Although LF/HF during whole night sleep did not differ significantly among three trials, HF in HYP showed significantly lower value compared to REST. The lowered HF during sleep may be due to increased sympathetic activity during the exercise in hypoxia. In conclusion, endurance exercise in hypoxia changed automatic nerve activity during post-exercise and impaired the parasympathetic nervous activity during sleep compared to the day without exercise.

PUPIL DYNAMICS IMPLIES AN INCREASE IN EXERCISE-EVOKED AROUSAL BY HYPOXIA: ASSUMING THE INVOLVEMENT OF ELEVATED CARDIORESPIRATORY RESPONSES

YAMAZAKI, Y., LEE, D., KUWAMIZU, R., AOIKE, N., SOYA, H.

UNIVERSITY OF TSUKUBA

INTRODUCTION: While exercising in a hypoxic condition is becoming popular, the brain state during that remains unclear. Arousal is one of the typical brain states that may be altered prominently during exercise and potentially by hypoxia as well. However, it is challenging to directly measure arousal-related brain activity during exercise. Pupil diameter has been thought to reflect the arousal state and may be a useful indicator of the arousal state during hypoxic exercise. Hypoxia increases relative exercise intensity, such as cardiorespiratory responses, during exercise, potentially resulting in enhanced exercise-induced pupil dilation. To address this issue, we explored whether pupil dilation during exercise is enhanced by a hypoxia-induced increase in relative exercise intensity by examining the difference in pupil dynamics when the work rate (WR) and heart rate (HR) during exercise were matched.

METHODS: A total of thirty-six participants were recruited for this study. The experiments consisted of two conditions: hypoxia (HY) and normoxia (NO) conditions. In the HY condition, participants performed 10 min of moderate-intensity exercise with a normobaric hypoxic gas inhalation (FIO2 = 0.16). In the NO condition, participants inhaled ambient air instead of the hypoxic gas. The pupil diameter was measured before, during, and after the exercise. In Experiment 1 (n = 18, fe-

males = 8, 22.3 ± 2.4 years), WR was matched between conditions. In Experiment 2 (n = 18, females = 9, 20.6 ± 2.3 years), HR was matched between conditions by adjusting the exercise intensity of the NO condition.

RESULTS: HR and ventilation during exercise were higher in the HY condition in Experiment 1 but were equal in Experiment 2, indicating that HR was successfully matched in Experiment 2. The saturation of percutaneous oxygen during exercise in the HY condition was approximately 90% in both experiments. In both experiments, moderate-intensity exercise robustly dilated pupil diameter. When the WR was matched, exercise-induced pupil dilation was higher in the HY condition compared to the NO condition (dilation percentage from pre: NO = 109.6 ± 1.4%, HY = 114.1 ± 1.3%, p = 0.01). On the other hand, exercise-induced pupil dilation was similar between conditions when the HR during exercise was matched (dilation percentage from pre: NO = 112.4 ± 1.6%, HY = 113.1 ± 1.4%, p = 0.53).

CONCLUSION: Here we found that if the WR was matched, exercise-induced pupil dilation was higher in the HY condition compared to the NO condition; on the contrary, it was similar between conditions when the HR during exercise was matched. These results lead us to postulate that cardiorespiratory responses are potential candidates for hypoxia-induced arousal elevation during exercise. The finding of this study could deepen understanding not only of the specific brain states during hypoxic exercise but also of the fundamental mechanisms underlying exercise-induced arousal enhancement.

POST-INHIBITORY REBOUND POTENTIATION OF HEART RATE VARIABILITY AFTER ACUTE NORMOBARIC HYPOXIC EXPOSURE IN HEALTHY YOUNG SUBJECTS

DONGMIN LEE, YUDAI YAMAZAKI, RYUTA KUWAMIZU, NAOKI AOIKE, MASAHIRO OKAMOTO, AND HIDEAKI SOYA

UNIVERSITY OF TSUKUBA

INTRODUCTION: Higher heart rate variability (HRV) is associated with high-stress resilience, positive emotional response and high cognitive function. Several interventions (exercise, meditation, biofeedback) are used to improve HRV. Under hypoxic conditions, heart rate increases predominantly through sympathetic activity, ultimately worsening HRV. However, chronic intermittent hypoxia exposure has been reported to increase overall HRV and improve emotional status. This led us to postulate that autonomic compensatory regulation may work to augment cardiac parasympathetic activity and improve mood states after hypoxia-induced sympathetic tone. To address this hypothesis, we examined cardiac autonomic fluctuations and mood changes after acute hypoxic exposure.

METHODS: Twenty-one healthy young adult participants (age: 23.7 ± 0.6 yr; weight: 61.9 ± 2.5 kg; height: 168.8 ± 2.2 cm) randomly underwent both a hypoxia (HY) and a normoxia (NO) condition, each on different days. Participants sat at rest on an ergometer inhaling normobaric-hypoxic gas (HY; FIO2 = 13.5%) or ambient air (NO; FIO2 = 20.9%) for 10 min and rested for 20 min after hypoxia in ambient air. Every 5 min, participants were asked about their mood states. Percutaneous oxygen saturation (SpO2) was monitored by a fingertip pulse oximeter and HRV was measured with an electrocardiogram. We used the root mean square of successive differences (RMSSD) as an indicator of parasympathetic nerve activity and the standard deviation of NN intervals (SDNN) for overall HRV.

RESULTS: During the HY condition, SpO2 significantly decreased (approximately 88%) compared with the NO condition and was significantly recovered 5 min after hypoxic exposure. No significant autonomic fluctuation occurred in the NO condition during or after normoxia. In the HY condition, HR significantly increased during hypoxia compared to baseline ($p < 0.001$) and with the NO condition ($p < 0.001$). HR decreased after hypoxia to values significantly lower than baseline ($p < 0.001$) and than the NO condition ($p < 0.02$). The RMSSD significantly decreased during hypoxia compared to baseline ($p < 0.001$) and to the NO condition ($p < 0.001$). After hypoxia, it increased significantly compared to baseline ($p < 0.001$) and to the NO condition ($p < 0.02$). The SDNN significantly decreased during hypoxia compared with baseline ($p < 0.05$) and increased significantly after hypoxia compared with baseline ($p < 0.001$) and with the NO condition ($p < 0.008$). Only in the HY condition, pleasure level increased significantly after hypoxia compared to baseline ($p = 0.03$).

CONCLUSION: Under hypoxic conditions, fluctuation of the autonomic nervous system regulates the heart rate for physiological adaptation by the predominance of sympathetic activity. After hypoxia, contrariwise, post-inhibitory parasympathetic rebounded potentiation effects occurred together with pleasant mood change. These results suggest that acute short-term hypoxic exposure has potential as a novel intervention method to improve HRV.

THE ACUTE EFFECT OF FREEDIVING SESSION ON THE MEMORY OF FREEDIVERS

ALLINGER, J.1,3, BOUYEURE, A.3, NOULHIANE, M.3, LEMAÎTRE, F.1,2

1)CETAPS UR3238, FACULTY OF SPORTS SCIENCES, UNIVERSITY OF ROUEN, FRANCE; 2) CRIOBE UAR3278, CNRS-EPHE-UPVD, MOORÉA,FRENCH POLYNESIA; 3) INDEV INSERM U1181,UNIVERSITÉ PARIS CITÉ & UNIACT CEA-NEUROSPIN

INTRODUCTION: Competitive freediving is a recent sport that aims to achieve the longest or deepest possible apnea dive, generating significant hypoxia. The high metabolic oxygen demand of the brain makes hypoxia a critical challenge for brain function. Several studies appear to show impact of long apnea on neurocognitive health (1, 2) but usually only after a maximum apnea in the laboratory. We therefore determined the impact of a normal session of apnea training on neurocognitive performance in freedivers and developed a loading index for apnea training.

METHODS: Eighteen freedivers (14 men and 4 women, 35.8 ± 5.8 years, freediving practice for 5.25 ± 3.4 years) participated in this study. Two different freedivers were tested each week over a period of 9 weeks. Each week the sessions were different but lasted one and half hour. The freedivers performed four memory tests before and after the apnea training session. The four memory tests were: the digit span memory task (DSM), the phonemic fluency test (PF), the categorical

verbal fluency test (CF) and the mnemonic similarity task test (MST). During the session, a polar H10 heart rate monitor measured heart rate and apnea starts and ends were recorded. The paired samples t-Test was used to compare memory test before and after the apnea training session. Pearson correlations were used to test relationships between memory scores, training parameters and load index. A statistical level of $p< 0.05$ was accepted.

RESULTS: All memory test were no difference between before and after the training session ($p >0.05$). Their years of apnea practice were negatively correlated with PF ($p=0.01$, $r=-0.590$). The load index of each session calculated by: average percentage of bradycardia of the session * number of apnea in the session * average apnea time of the session; was negatively correlated only with MST after session ($p=0.007$, $r=-0.608$). The mean percentage of bradycardia in the session was positively correlated with the mean apnea time in the session ($p=0.045$, $r=0.477$).

CONCLUSION: Only one apnea training does not appear to affect cognitive function. However, the calculated load index shows that the longer a training with repeated apneas, the greater the impact on MST. The impact of numbers of years of apnea on PF could show dysfunction in the executive function of semantic memory.

THE EFFECTS OF THE MENSTRUAL CYCLE AND COMBINED HORMONAL CONTRACEPTIVE USE ON SATELLITE CELL REGULATION POST EXERCISE IN RECREATIONALLY ACTIVE WOMEN: A PILOT STUDY.

MCNULTY, K.L., ANSDELL, P., GOODALL, S., THOMAS, K., WALSHE, I., KRITIKAKI, E., TODRYK, S., SIMOES, D.C.M., ATKINSON, E., KENNAN, A., ELLIOTT-SALE, K.J., HOWATSON, G., HICKS, K.M.

NORTHUMBRIA UNIVERSITY

INTRODUCTION: Satellite cells (SC) play an important role in muscle regeneration. There is evidence to suggest that fluctuations in endogenous and exogenous sex hormone concentrations across the menstrual cycle (MC) and with combined hormonal contraceptive (CHC) use might influence SC regulation post exercise[1], which could have implications for the time course of recovery post exercise as well as long term adaptation in women. However, currently, evidence is limited. As such, the purpose of this study was to investigate the effect of the MC and CHC use on the SC response post exercise.

METHODS: Nine recreationally active women (27 ± 5 years); five naturally menstruating and four CHC users, took part. Participants performed a strength-based resistance protocol, consisting of five sets of eight repetitions of leg press exercise at 80% of one-repetition maximum, in three phases across the MC (early follicular [EF], late follicular [LF], and mid-luteal [ML] phases) or CHC cycle (withdrawal, and early and late consumption). Vastus lateralis muscle biopsies obtained pre and 72-hrs post exercise were analysed for local mRNA expression of the myogenic markers PAX7, MYOD, myogenin, and cyclin D1. Gene expression was measured using the quantitative real-time PCR technique.

RESULTS: There was no difference in the expression of all myogenic markers pre-exercise across phases or between groups. In naturally menstruating women at 72-hrs post exercise, PAX7, MYOD, and cyclin D1 mRNA expression was higher in the EF phase compared to all other phases ($P \leq 0.001$), but there was no difference in myogenin. In naturally menstruating women the estimated PAX7:MYOD ratio at 72-hrs post exercise indicated that SCs were undergoing myogenic proliferation (ratio = 1) in the EF phase and myogenic differentiation (ratio < 1) during the LF phase, whereas SCs remained at the quiescent stage (ratio > 1) in the ML phase. In CHC users at 72-hrs post exercise MYOD was higher in the withdrawal phase compared to both consumption phases ($P \leq 0.003$), whereas myogenin was higher during the late consumption phase compared to all other phases ($P \leq 0.022$), but there was no difference in PAX7 and cyclin D1. In CHC users the estimated PAX7:MYOD ratio at 72-hrs post exercise indicated that SCs were undergoing myogenic differentiation (ratio < 1) in the withdrawal phase, whereas SCs remined at the quiescent stage (ratio > 1) in the consumption phases. Analysis of sex hormone concentrations is ongoing.

CONCLUSION: These findings indicate that changes in endogenous and exogenous sex hormones across the MC and with CHC use affect SC regulation during the extended recovery time from exercise in a group of recreationally active women. These results could have important implications for the optimal management of the recovery process in women. Further research is required to elucidate whether these changes influence long-term adaptation responses to training in women.

RESPONSE OF SERUM AND FUNCTIONAL BIOMARKERS AFTER EXERCISE INDUCED MUSCLE DAMAGE. DIFFERENCES BETWEEN MALE AND FEMALE.

MORENO-SIMONET, L., COSIO, P.L., LLORET, M., PADULLES, X., PADULLES, J.M., CADEFAU, J.A.

INSTITUT NACIONAL DEDUCACIÓ FÍSICA DE CATALUNYA - UNIVERSITAT DE BARCELONA

INTRODUCTION: Exercise-induced muscle damage (EIMD) results from an unaccustomed or hight intensity exercise. This physiological process is characterized by loss of strength, delay onset muscle soreness and muscle protein release on serum (1). Sex-differences on EIMD have been studied but results were not conclusive. Most of studies measure muscle damage though creatine kinase (CK) as a single marker. Other markers are recently used to measure muscle damage as sarcomeric mitochondrial creatine kinase (sMtCK) to reflect mitochondrial disruption (2), or CK-MB, localized on slow fibres. To our knowledge, there are no sex-difference studies that measure these markers after EIMD. In terms of functional parameters, whereas some studies report no sex difference on relative strength and recovery over time (3), other suggest a faster recovery on females (4). The main objective is to determine the difference on serum and functional markers between male and female after a high intensity exercise.

METHODS: Thirty healthy males (n=16, 23 ± 0.7 years, BMI 23.8 ± 0.4) and females (n=14, 22 ± 0.8 years, BMI 22.1 ± 0.6) performed 10 repeated maximal 40m sprints with a rest of 3 minutes between repetitions. Changes on force generating capacity, as an indirect markers of muscle damage, and serum levels of muscle enzymes (CK, sMtCK and CK-MB) were measured at baseline and 24-, 48- and 72-hours post-exercise. Two-way repeated measure ANOVA (time x sex) and a pairwise test, with a Bonferroni adjust, was used to identify changes from baseline and differences between groups. Data are presented as mean ± SD and the level of significance was set at $p < 0.05$.

RESULTS: CK activity peak was significative higher on males (p= 0.020). In the same way, sMtCK and CK-MB values were significative higher on males from baseline (p=0.018) to 48h (p= 0.003), and from baseline (p=0.022) to 24h (p= 0.033) after EIMD respectively. However, males recover baseline values faster than females. On functional parameters there are no differences on loss of relative strength between males and females (F= 1.589; p=0.200).

CONCLUSION: Serum markers response after EIMD is different between males and females, reflecting a greatest membrane, mitochondria and sarcomere, damage on males, however, males recover faster their baseline values, suggesting a more efficient recovery process. Functional markers response is similar between sex.

INTRODUCTION: Microvascular perfusion is essential for post-exercise skeletal muscle recovery to ensure adequate delivery of nutrients and growth factors and removal of accumulated waste products. Microvascular perfusion is regulated by both functional and anatomical factors, such as dilation of terminal arterioles and muscle fiber capillarization, respectively. This study assessed the relationship between various indices of muscle fiber capillarization and microvascular perfusion at rest and during recovery from resistance exercise in healthy, older adults.

METHODS: In this cross-sectional study, sixteen healthy, older adults (72±6 y, 5/11 male/female) participated in an experimental test day during which a muscle biopsy from the M. vastus lateralis was collected and microvascular blood volume was determined at rest and following 10 and 40 min of recovery after a bout of resistance exercise by contrast-enhanced ultrasound in the contralateral M. vastus lateralis. Immunohistochemistry combined with fluorescent microscopy was performed on the muscle biopsy samples to determine various indices of mixed and fiber type specific muscle fiber capillarization. Microvascular blood volume measurements were compared using a one factor repeated measures ANOVA with time as within-subjects factor. Pearson (r) correlation analyses were performed between different measures of muscle fiber capillarization and microvascular blood volume. Statistical significance was accepted as $P<0.05$. All data are expressed as mean±SD.

RESULTS: Microvascular blood volume at t=10 was higher compared with rest and t=40 (27.2±4.7 vs 3.9±4.0 and 7.0±4.9 a.u., respectively, both $P<0.001$). Microvascular blood volume at t=40 was higher compared with rest ($P<0.001$), but lower compared with t=10 ($P<0.001$). The microvascular blood volume increase from rest to t=10 was higher compared with rest to t=40 (6.0±3.1 vs 2.5±1.4 fold, $P<0.001$). No associations were observed between different indices of mixed muscle fiber capillarization and microvascular blood volume at rest or during recovery from exercise. Type 2 muscle fiber capillary-to-fiber ratio (C/Fi) was moderately correlated with the microvascular blood volume increase from rest to t=10 min ($r=0.59$, $P<0.05$). Type 2 muscle fiber capillary contacts and capillary-to-fiber exchange index were strongly correlated with the microvascular blood volume increase from rest to t=40 min ($r=0.66$, $P<0.01$ and $r=0.64$, $P<0.01$, respectively). Finally, a

very strong correlation was observed between type 2 muscle fiber C/Fi and the microvascular blood volume increase from rest to t=40 min (r=0.81, P<0.001).

CONCLUSION: Resistance exercise greatly increases microvascular perfusion for up to 40 min after exercise cessation in healthy, older adults. This exercise-induced increase in microvascular perfusion seems to be restricted by type 2 muscle fiber capillarization specifically.

AEROBIC EXERCISE AMELIORATES MOUSE LYMPHEDEMA BY PROMOTING LYMPHANGIOGENESIS

PARK, H., SONG, Y., LEE, S., PARK, H., KANG, H.

KYUNG HEE UNIVERSITY

INTRODUCTION: Lymphedema is the abnormal retention of protein-rich interstitial fluid due to impaired lymphatic function. Secondary or acquired lymphedema occurs following surgery or radiation in cancer survivors. Over time, they suffer from limb swelling, reduced mobility, and recurrent infections. Lymphedematous tissue shows inflammation, adipogenesis, and fibrosis but the mechanism underlying the development of lymphedema is unknown. Currently, physical therapy such as compression bandage or massage is the only option available for alleviating lymphedmea (1). A previous human study indicates that exercise may help to reduce lymphedema (2). Endurance exercise stimulates lymphangiogenesis (3). Using a mouse model with hind leg lymphedema, we hypothesized that exercise reduces the size of lymphedema by promoting lymphangiogenesis.

METHODS: 7-week-old male ICR mice were used for the hind leg lymphedema, which involves removal of the superficial inguinal node, the popliteal lymph node, and the deep inguinal, and electrocauterization of the femoral lymphatic vessel (4). Groups were divided into Normal, Lymphedema (Lym), and Lym/Exercise (Lym/E) (n = 5). The Lym/E mice were subjected to forced wheel running exercise 3 days after surgery. Exercise consisted of 30 min at a low intensity of 4.68 m/min once a day. The Lym/E mice underwent exercise for 7 days, and during the same period, the Lym mice were left on the wheel. Leg swelling was measured with a Vernier caliper every 3 days, and tissue was harvested after the last exercise. The gene expression of lymphangiogensis markers such as LYVE-1, VGFR3, and Prox1 was determined using realtime RT-PCR. The quantification of cDNA copy number was calculated using the ΔΔCt values. Data were analyzed by analysis of covariance, and statistical significance was set at $p<0.05$. All data are expressed as mean and standard deviation.

RESULTS: Swelling of the lymphedema was significantly reduced by 66% in the Lym/E group compared to the Lym group ($p<0.01$). Among the lymphangiogenesis markers tested, downregulation of Prox1 was observed in the Lym group compared to the normal group ($p<0.05$). Upregulatione of LYVE-1 ($p<0.05$), VEGFR3 ($p<0.05$), and Prox1($p<0.05$) was observed in the Lym/E group compared with the Lym group. The expression levels of Prox1 in the Lym/G group were even higher than the Normal group ($p<0.05$).

CONCLUSION: Aerobic exercise ameliorated lymphedema by promoting lymphangiogenesis. These data suggest that aerobic exercise is beneficial in the management of lymphedema.

HIIT TRAINING IN PREVIOUSLY INACTIVE MALES ENHANCES ORAL NITRATE AND NITRITE LEVELS WITHOUT INCREASING DENTAL CARIES RISK

SIMPSON, A.1, EASTON, C.1, HENRIQUEZ, F.1, ARCHETTI, L.2, PILOTTO, A.2, BESCOS, R.3, PORCELLI, S.2, BURLEIGH, M.1

1. UNIVERSITY OF THE WEST OF SCOTLAND 2. UNIVERSITÀ DI PAVIA 3. UNIVERSITY OF PLYMOUTH

INTRODUCTION: Dietary nitrate (NO3-) is reduced to nitrite (NO2-) by commensal oral bacteria. NO2- is converted to vasodilatory nitric oxide (NO) or stored for use when endogenous NO production is impaired. NO3- supplementation reduces the O2 cost of exercise and improves exercise capacity1. NO3- has also been proposed as a prebiotic to encourage growth of bacteria associated with dental health and shift the oral environment away from the conditions seen in disease following carbohydrate consumption2. This has implications for athletes as many factors relating to exercise training drive dental disease, such as carbohydrate supplementation regimes and exercise induced dehydration, favour the bacteria that cause dental caries3.

METHODS: 11 inactive (VO2peak 45 ml·min−1·kg−1), healthy males (25±5 years, 64.0±11.2kg, 171±6 cm) underwent 8-weeks of thrice weekly HIIT followed by 3-months detraining. Unstimulated saliva was collected at baseline (BL), after training (TR), and after detraining (DETR). High performance liquid chromatography was used to quantify NO3- and NO2-. Glucose, lactate and pH were also quantified. Median and IQR is reported for all of the salivary measurements, where differences were measured using Friedmans test, followed by Bonferroni adjusted post-hoc testing where appropriate.

RESULTS: BL NO3-(268.0, 194.6-813.6μM) and NO2-(56.87, 34.47-146.8μM) increased to (455.6, 250.4-931.7μM) and (151.1 105.1-179.6μM) respectively after TR ($p\leq0.018$). Following DETR, NO3-(476.0, 216.0-855.6μM) and NO2-(95.55, 58.98-118.4μM) decreased ($p\leq0.033$). No significant differences were seen between BL and DETR ($p\geq1.00$). Neither TR or DETR were associated with changes in salivary glucose, lactate or pH ($p\geq0.155$).

CONCLUSION: Oral NO3- reduction increases following HIIT and the physiological adaptations and changes to the NO3-reducing oral microenvironment it induces. Prebiotic NO3- could further enable health associated NO3- reducing bacteria to outcompete pathogens, discouraging disease development and improving exercise performance. Oral glucose and

lactate did not increase, indicating thrice weekly HIIT training in isolation does not impact the risk of developing dental disease.

EFFECTS OF COLD-WATER IMMERSION ON RECOVERY OF NEUROMUSCLULAR AFTER INTERMITTENT-SPRINT EXERCISE

LIU, Z.H., WU, Y.G., ZHENG, X.Y.

SHANGHAI UNIVERSITY OF SPORT

INTRODUCTION: Contemporary sports activities impose extremely high physical demands on athletes. Many of them are subjected to treatments that involve cold-water immersion (CWI) to obtain therapeutic effects. However, some researchers maintained that CWI could decrease tissue temperature, impair deep feeling in the body, induce neuromuscular deficits occur after cold application and advise athletes against undertaking dynamic training immediately after cryotherapy. However, the effects of CWI on neuromuscular are inconsistent (Costello et al., 2011; Minett et al., 2014), and the mechanism of CWI effects on proprioception are not uniquely conclusive. The aim of this study was to clarify the effects of the effects of post-exercise cooling on recovery of proprioception, physiological, and perceptual responses following intermittent-sprint exercise.

METHODS: Fifteen physically active males performed intermittent repeated sprint that comprised cycling at 40% Wattmax for 30s, followed by 120% Wattmax for 30s until fatigue. After exercise, a 10 min recovery intervention of a passively seated rest (control, CON), or CWI (15°C) was underwent. Active movement extent discrimination assessment (AMEDA) of the right knee which is an index of proprioception was assessed with cerebral oxygenation and muscle activation pre- and post-exercise, post-intervention, and 24h post-exercise. The oxygenated ([HbO]), and deoxygenated ([HHb]) cerebral hemoglobin concentrations throughout the AMEDA test were measured via a functional near-infrared spectroscopy, and The muscle activation was measured via a surface electromyography, and the data were analyzed using wavelet analysis for root mean square (RMS), median frequency (MF) and mean power frequency (MPF). Physiological and perceptual measures were also collected.

RESULTS: Compared to pre-exercise, AMEDA at the post-intervention remained significantly worse in the CON ($P < 0.05$), but no significant differences were observed in the CWI ($P > 0.05$). CWI effectively reduced core temperature, skin temperature and heart rate, decreased perceived muscle soreness and thermal sensation, but failed to affect RMS, MF and MPF of knee extensors and flexors. Neither HbO nor HHb at the left precentral gyrus, postcentral gyrus, anterior parietal cortex and posterior parietal cortex was changed by CWI.

CONCLUSION: Neuromuscular control is based on subconscious information from mechanoreceptors and processes within the central nervous system that allow control movement through coordinated muscle activity (Furmanek et al., 2014). In the present study, we firstly evidenced that CWI failed to affect AMEDA, brain or muscle activation, these results indicate that CWI post-exercise has no effects on recovery of neuromuscular. CWI at 15°C for 10 min decreased the body temperature, while did not change in proprioception. We suggest that the application of CWI is safe for athletes regarding proprioception.

SPECIFIC IMPACT OF A COVID-19 INFECTION ON TRAINING MODALITIES OF ENDURANCE TRAINED ATHLETES.

DURAND, F., YONNET, A., MERIC, H., BOUDRY, F.

UNIVERSITY OF PERPIGNAN VIA DOMITIA

INTRODUCTION: Lung is the organ most affected by an infection by coronavirus disease 2019 (Covid-19). Impairment of lung function and its adaptations to exercise have been reported in post-infected healthy individuals [1]. On the other hand, some trained endurance athletes reach and outstrip the functional capacity of their respiratory system limiting endurance exercise [2]. In this context, we hypothesized that endurance-trained athletes would have more difficulty returning to training at their best level after an infection. The objective of this study was to evaluate the impact of a COVID-19 infection on the training modalities of endurance-trained athletes compared to non-endurance-trained athletes.

METHODS: A self-administered online form was carried via LimeSurvey® software between April and May 2022. The questionnaire unfolded if and only if the person had been infected and aged 18 years and more. Four hundred and sixty-eight participants responded to the questionnaire. The questionnaire was distributed through social media platforms, sport teams and federations. It included four sections: demographic and epidemiologic, sport profile of athletes, characteristics of infection, consequence of infection on training modalities and symptoms.

RESULTS: All participants were screened by PCR test (63.96%) or antigenic test (36.54%). Auto-test were excluded. The participants mean age was 29.6 ± 13 years and males represented 52.78% of participants. The classic symptoms were found (headache, cough and fever) during 2 at 7 days. According to the type of sport practice and training modalities, we discriminated between endurance trained athletes (END, n= 246) and non-endurance trained athletes (NEND, n= 222). No between group difference was reported for infection symptoms, persistence of symptoms and difficulties related when

training resumed. END reported a significant trend (p = 0.08) to require more time to resume training than NEND (57.5 vs. 42.5% respectively). Whereas, our study reported a significant reduction of training volume in END compared to NEND (respectively 74.4 vs 25.6%, p<0.001) associated with a longer recuperation after training sessions (respectively 61.7 vs 38.3%, p<0.05).

CONCLUSION: These results highlight that covid-19 infection induces specific changes in the training modalities of endurance trained athletes, causing them to reduce training volume and increase recovery time compared to non-endurance athletes.

REGULATION OF ENDOCANNABINOIDS AND SATELLITE CELLS BY RESISTANCE EXERCISE IN HYPOXIA

VAN DOORSLAER DE TE RYEN, S., DALLE, S., TERRASI, R., KOPPO, K., MUCCIOLI, G.G., DELDICQUE, L.

UNIVERSITÉ CATHOLIQUE DE LOUVAIN

INTRODUCTION: Endocannabinoids are small lipids that regulate energy metabolism, homeostasis and inflammation in response to stress, a.o. exercise. In addition, hypoxic conditions regulate myogenesis and, when combined with endurance exercise, upregulate plasma endocannabinoids. The purpose of this study was to analyze endocannabinoids and satellite cells markers in response to acute and long-term resistance exercise in hypoxic and normoxic conditions.

METHODS: Healthy young men performed an acute or a long-term resistance exercise (single leg extension) either in normoxia (FiO2=0.21) or in normobaric hypoxia (FiO2=0.14). For the acute exercise, vastus lateralis muscle biopsies were taken at 15min and 4h post-exercise and blood samples were taken before and 2h after exercise. The resistance training lasted for 4 weeks, with 3 sessions a week. Vastus lateralis biopsies and blood samples were taken before and after the training period. Plasma levels of endocannabinoids were measured by mass spectrometry. mRNA levels and protein expression of different markers of the endocannabinoid system and of myogenesis in skeletal muscle were measured. Statistical analysis was realized using a linear mixed model in R.

RESULTS: Following an acute resistance exercise, plasma 2-AG (p=0.029) and PEA (p=0.038) decreased in normoxia. CNR1 mRNA also decreased from 15min to 4h post-exercise in normoxia (p=0.022) and lower CB1 at 4h post-exercise in hypoxia (p=0.018) was observed. MRF4 mRNA, a marker of satellite cell differentiation, decreased from 15min to 4h post-exercise (p<0.001) whereas Myf5 and MyoD, which characterize satellite cell proliferation, remained unchanged by exercise and hypoxia.

Plasma endocannabinoids AEA (p=0.013), PEA (p=0.003) and OEA (p=0.037) decreased from before to after 4 weeks resistance training. No differences were observed in mRNA and protein expression of the endocannabinoid receptors, excepted CNR1 mRNA levels that increased from before to after training (p=0.015). Hypoxia increased the levels of Pax7 (p=0.07), a marker for satellite cell activation, and MyoD mRNA (p=0.006) and protein expression (p=0.059). Exercise training increased myogenin (p=0.029) and MRF4 (p=0.021) mRNA levels.

CONCLUSION: Our results show that resistance exercise and training decrease plasma endocannabinoid levels, which is opposite to the increase commonly observed following endurance exercise. Endocannabinoid receptor activation was shown to increase MyoD and myogenin expression (Zhang et al., 2019). Our observations are in line with this as acute resistance exercise lowered CB1 expression and MRF4 mRNA levels, and exercise training increased CNR1 together as well as Pax7, myogenin, MyoD and MRF4. CB1 and CB2 expression was increased following a resistance training in old people (Dalle & Koppo, 2021). Therefore, the endocannabinoid system could contribute to the regulation of myogenesis. This could explain the opposite activation of endocannabinoids in response to endurance and resistance exercise.

CONCOMITANT CHANGES IN LACTATE AND FAT OXIDATION KINETICS DURING EXERCISE

BENÍTEZ-MUÑOZ, J.A.1, GUISADO-CUADRADO, I.1, ROJO-TIRADO, M.A.1, ALCOCER-AYUGA, M.1,2, ROMERO-PARRA, N.1,3, PEINADO, A.B.1, CUPEIRO, R.1

1. UNIVERSIDAD POLITÉCNICA DE MADRID. 2. OLYMPIA SPORT & LIFESTYLE CENTER. QUIRONSALUD. 3. UNIVERSIDAD REY JUAN CARLOS

INTRODUCTION: Lactate concentrations have been positively correlated with carbohydrate oxidation and negatively associated with fat oxidation in participants with different metabolic characteristics (1). However, no previous study has investigated this association in different situations influencing lactate kinetics. Thus, the purpose of this study was to determine whether changes in lactate kinetics (due to glycogen depletion or heat) alter the fat oxidation pattern during a maximal incremental test.

METHODS: Eight men (21.9±1.4years; 70.7±4.9kg; 1.7±0.02m) and six women (22.3±0.5years; 62.9±4.0kg; 166.5±5.2cm) performed an incremental test on a cycle-ergometer (Lode Excalibur, Germany) in three situations: control, glycogen depletion and hyperthermia (~36°C). It started at 30W and increased 30W every 3 minutes until exhaustion. Capillary lactate levels were analysed using a lactate analyser (Biosen-C-line-EKF Diagnostic, Germany) at rest, in the last 30 seconds of

each step and immediately post-exhaustion. Mean substrate oxidation of the last minute of each step was estimated by indirect calorimetry using a gas analyser (Jaeger-CareFusion, Hochberg, Germany). A mixed linear model was used to compare the individual response (random effect) of lactate or fat oxidation between situations (fixed effect) at the different intensities of the protocol (fixed effect), and Bonferroni for post hoc analyses. Association between lactate and fat oxidation was calculated using Pearson correlation.

RESULTS: Lactate concentration was different between situations ($p<0.001$). Specifically, it was higher in heat (4.5±0.26 mmol/L) compared to control (3.27±0.26 mmol/L; $p<0.001$) and glycogen depletion (2.82±0.26 mmol/L; $p<0.001$). It was algo higher in control compared to glycogen depletion ($p=0.035$). On the other hand, fat oxidation was different between situations ($p<0.001$). It was higher in glycogen depletion (0.33±0.03 g/min) compared to control (0.12±0.03g/min; $p<0.001$) and heat (0.1±0.03g/min; $p<0.001$). Moreover, lactate was negatively correlated with fat oxidation in control ($R2=0.966$; $p<0.001$), glycogen depletion ($R2=0.962$; $p<0.001$) and heat ($R2=0.894$; $p<0.001$).

CONCLUSION: The higher lactate concentration along with a lower fat oxidation observed in the heat situation, and the lower lactate concentration coupled with a higher fat oxidation with glycogen depletion, support the inhibitory effect of lactate on fat oxidation, as previously suggested (1). From a practical perspective, as the inverse correlations between lactate and fat oxidation between situations are strong, lactate measurement alone is an effective way to indirectly evaluate fat oxidation and vice versa. In conclusion, changes in lactate kinetics due to the different situations alter the pattern of fat oxidation during an incremental exercise.

THE MEDIATING ROLE OF BODY COMPOSITION IN THE RELATIONSHIPS OF PHYSICAL ACTIVITY AND SEDENTARY TIME WITH INSULIN RESISTANCE IN CHILDREN

MORGAN, E., BARKER, A., VLACHOPOULOS, D., LAITINEN, T., BRAGE, S., HAAPALA, E.A., LAKKA, T.A.
UNIVERSITY OF EXETER

INTRODUCTION: Given the childhood origins of cardiometabolic diseases, childhood levels of insulin resistance (IR) are an important risk factor for developing type 2 diabetes later in life. IR is also associated with adiposity. A reduction in fat mass is seen through a reallocation of sedentary time (ST) to moderate-to-vigorous physical activity (MVPA). It remains unclear, however, whether PA is associated with IR independently of body composition. This study aimed to analyse the mediating role of body fat and lean mass in the relationships of MVPA and ST with IR in children.

METHODS: This study used baseline data from the Physical Activity and Nutrition in Children (PANIC) study. In total, 357 (180 girls, 177 boys) 6–8-year-olds were included in the statistical analyses. Homeostatic Model Assessment for Insulin Resistance (HOMA-IR) was calculated from fasting plasma glucose and serum insulin levels as a measure of IR. Body fat and lean mass were assessed using dual-energy X-ray absorptiometry. A combined heart rate and body movement sensor was used to quantify MVPA and ST. The mediating role of body fat and lean mass in the relationships of MVPA and ST with HOMA-IR adjusted for age and puberty was assessed using a four-way decomposition counterfactual mediation analysis, split by sex, using the Med4way command in Stata.

RESULTS: There was a statistically significant negative total effect for the association between MVPA and HOMA-IR in girls ($B=-0.07$, $p=0.02$) and boys ($B=-0.14$, $p<0.001$) and a statistically significant positive total effect for the association between ST and HOMA-IR in girls ($B=0.14$, $p<0.001$) and boys ($B=0.10$, $p=0.002$).

With fat mass as the mediator, there was a statistically significant pure indirect effect for the association between MVPA and HOMA-IR in girls ($B=-0.029$, $p=0.010$) and boys ($B=-0.085$, $p<0.001$) and for the association between ST and HOMA-IR in girls ($B=0.029$, $p=0.035$) and ($B=0.076$, $p<0.001$). A statistically significant controlled direct effect was also seen for the association between ST and HOMA-IR, when mediated by fat mass, in girls ($B=0.106$, $p=0.002$).

With lean mass as the mediator, no pure indirect effects were statistically significant. Instead, a statistically significant controlled direct effect was found for the association between MVPA and HOMA-IR in girls ($B=-0.068$, $p=0.023$) and boys ($B=-0.155$, $p<0.001$) and for the association between ST and HOMA-IR in girls ($B=0.139$, $p<0.001$) and boys ($B=0.087$, $p=0.005$).

CONCLUSION: The relationships of MVPA and ST with HOMA-IR are mediated by body fat mass but not body lean mass. The prevention of type 2 diabetes by increasing PA should also focus on reducing body fat mass as a mechanism to decrease IR.

EFFECTS OF PHYSICAL ACTIVITY LEVEL ON QUADRICEPS FEMORIS MUSCLE AND INTRAMUSCULAR ADIPOSE TISSUE IN THE ELDERLY

ANJIKI, K., ANDO, S., TOMIGA, R., KOSE, Y., FUKUOKA, S., SUDO, M., YAMADA, Y., EBINE, N., HIGAKI, Y., TANAKA, H., HATAMOTO, Y.

THE UNIVERSITY OF ELECTRO-COMMUNICATIONS

INTRODUCTION: Sarcopenia is an age-related progressive loss of skeletal muscle mass and function, and the muscle loss is particularly prominent at the anterior thigh muscles. Furthermore, intramuscular adipose tissue modulates insulin sensitivity and triggers inflammation. Hence, it is important to investigate whether physical activity level (PAL) is associated with thigh muscle mass and intramuscular adipose tissue in the elderly. However, whether PAL is associated with thigh muscle and intramuscular adipose tissue is not well understood. The purpose of this study was to examine the association between PAL and thigh muscle cross sectional area (CSA)/intramuscular adipose tissue.

METHODS: Twenty-nine elderly (20 females) participated in this study (age: 70.9 ± 7.1 yr.). We measured total energy expenditure for 16 days using the doubly labelled water method [1]. Basal metabolic rate was predicted using the Ganpule equations for adult men and women [2]. Then, PAL was calculated by dividing the total energy expenditure by basal metabolic rate. The quadriceps muscle CSA and intramuscular adipose tissue were assessed at mid-thigh (50% of the femur) regions using magnetic resonance imaging. We performed the Spearman rank correlation test to examine relationships between PAL and quadriceps femoris muscle CSA/intramuscular adipose tissue content. Data are expressed mean ± SD or median (interquartile range).

RESULTS: Mean PAL, quadriceps femoris muscle CSA, and intramuscular adipose tissue content was 1.47 ± 0.14, 41.8 (36.1-48.3) cm2, and 2.3 (1.7-3.6) cm2. PAL was not correlated with quadriceps femoris muscle CSA (ρ = -0.033, p = 0.865). Conversely, we observed a significant correlation between PAL and intramuscular adipose tissue content (ρ = -0.405, p = 0.030). These results indicate that PAL is associated with intramuscular adipose tissue content, but not with quadriceps femoris muscle CSA in the elderly.

CONCLUSION: The present findings suggest that physical activity may reduce the risk of diseases derived from accumulation of intramuscular adipose tissue in the elderly.

IMPACT OF EXERCISE TRAINING ON THE RELATIONSHIP BETWEEN COGNITIVE OUTCOMES, PERCEPTION OF MEMORY AND BRAIN BLOOD FLOW IN OLDER ADULTS.

SILVA, G.O., CLARK, M., LAUTENSCHLAGER, N.T., PESTELL, C.F., COX, K.L., AINSLIE, P.N., CARTER, H.H., NAYLOR, L.H., GREEN, D.J.

THE UNIVERSITY OF WESTERN AUSTRALIA, NOVE DE JULHO UNIVERSITY, UNIVERSITY OF BRITISH COLUMBIA

INTRODUCTION: Cerebrovascular dysfunction may contribute to cognitive impairment in older adults [1]. Exercise is recommended for the management and prevention of cerebrovascular diseases and preserves brain health and cognition [2]. It is not currently known, however, if improvement in cognition is related to changes in cerebrovascular function. We hypothesized that improvements in cognition and perception of memory would relate to changes in cerebral blood flow velocity in older adults following supervised centre-based exercise programs.

METHODS: Sixty-three sedentary older individuals (age=62±7, 26%♂) were randomised to a land-walking (LW), water-walking or usual care control group. Exercise trained individuals (n=41, age=63±7, 27%♂) undertook supervised monitored training 3 times/week for 50 min per session, across 24 weeks [3]. Cognitive outcomes included Repeatable Battery for the Assessment of Neuropsychological Status (RBANS), with perception of memory assessed using the Memory Complaint Questionnaire (MAC-Q). Middle cerebral artery blood flow velocity (MCAv) was assessed at rest and in response to neurovascular coupling, hypercapnic reactivity, and cerebral autoregulation. To maximise power, we pooled the training groups and performed regression analysis for change in cognitive, perceived memory scores and MCAv, adjusted for age, sex, and education level.

RESULTS: No significant group changes in cognition or memory were detected, but improvement in RBANS with training was significantly correlated with decreased resting MCAv (r = -0.386, P = 0.024) in the trained individuals. Improvement in MAC-Q with training was also correlated with a decrease in MCAv (r = 0.357, P = 0.035). No significant correlations were detected between RBANS, MAC-Q and other cerebrovascular outcomes.

CONCLUSION: Improvements in neuropsychological status and perception of memory were associated with reduced cognitive demand at rest, as indicated by decreased brain blood flow velocity. Our results suggest that cognitive efficiency is enhanced with exercise training. We speculate that exercise training may increase cerebrovascular reserve in patients at risk of cognitive impairment by decreasing the blood flow required to subsidise cognitive demand.

EFFECTS OF ONCE-WEEKLY HIGH-INTENSITY INTERVAL TRAINING ON DXA-DERIVED VISCERAL ADIPOSITY IN CENTRALLY OBESE ADULTS: PRELIMINARY FINDINGS OF A RANDOMIZED CONTROLLED TRIAL

LEUNG, C.K., BERNAL, J.D.K., YU, A.P., RECCHIA, F., SIU, P.M.

THE UNIVERSITY OF HONG KONG

INTRODUCTION: Obesity is a global public health priority with alarming prevalence and is a chronic, multifactorial disease that substantially increases the risk of numerous non-communicable diseases (NCDs). Notably, central obesity, characterized by the excess accumulation of adipose tissue in the abdominal region, has been shown to better discriminate the risk of excess adipose tissue on developing NCDs. Integral to the long-term management of obesity is lifestyle modification with physical activity being considered a cornerstone of obesity management. Despite regular physical activity being a key protective factor for the prevention and management of obesity, participation remains inadequate. Among physically inactive individuals, lack of time is the most commonly identified barrier to regular physical activity. High-intensity interval training (HIIT) consists of high-intensity exercise interposed with active recovery bouts and is considered a time-efficient exercise modality that may alleviate the 'lack of time' barrier to physical activity. In this study, we present the preliminary findings of a randomized controlled trial that aimed to examine the effects of once-weekly HIIT on reducing visceral adiposity in centrally obese adults.

METHODS: In this two-arm, assessor-blinded, randomized controlled trial, 150 adults (BMI: 29.95±3.95, Age: 46±10) with central obesity (defined as BMI≥25 and waist circumference of ≥80cm for women and ≥90cm for men) were randomly allocated in a 1:1 ratio to a HIIT (n=75) or usual care control group (n=75) for 12 months. Usual care control group (CON) participants attended a 70-min health education class every 2 weeks for 12 months. HIIT group participants attended a 35-min HIIT session once a week under the supervision of certified athletic coaches for 12 months. The training was performed on a treadmill using the 4x4-min HIIT protocol, whereby the participants ran for four 4-min bouts at 85-95% peak heart rate with a 3-min active recovery between each bout. Outcome assessments were conducted before and after the 12-month intervention. Visceral adipose tissue mass was assessed using dual-energy x-ray absorptiometry (DXA). Generalized estimating equation (GEE) was used to assess the treatment effects with baseline measurements used as covariates. A P value of <0.05 was considered statistically significant.

RESULTS: After 12 months of intervention, the visceral adipose tissue mass was significantly reduced in the HIIT group when compared to the CON group (HIIT: -54g -7.70% vs CON: +5g +0.72%, $P<0.05$).

CONCLUSION: These findings demonstrate that HIIT performed once-weekly for 35-min can effectively induce a substantial reduction in visceral adipose tissue mass. This suggests that low-frequency HIIT is a feasible, practical and effective approach to reduce visceral adiposity in centrally obese adults.

A RANDOMIZED CROSSOVER TRIAL TO ASSESS THE EFFECT OF TIME-RESTRICTED EATING COMBINED WITH RESISTANCE TRAINING ON HIGH-SPEED STRENGTH AND BODY COMPOSITION IN HEALTHY MALES

CORREIA, J.M., SANTOS, P., PEZARAT-CORREIA, P., MINDERICO, C., INFANTE, J., MENDONÇA, G.V.

FACULDADE DE MOTRICIDADE HUMANA

INTRODUCTION: Optimum nutrition is highly valuable for athletes aiming at maintaining or improving body composition and sports performance. Recently, intermittent fasting (IF) has gained popularity as an alternative to energy restriction (ER). IF is a dietetic approach that requires varying between fasting and feasting periods. Fasting typically extends beyond an overnight fast (≥ 12h), and feasting implicates feeding on limited time-windows (either with or without ER). There is preliminary evidence that IF may be an important strategy for improving exercise performance. To our knowledge, the impact of this specific dietary approach on high-speed strength (e.g. explosive strength) has not yet been examined. There is compelling evidence that RT is effective for enhancing high-speed strength over time. Yet, whether TRE affects the overall positive impact of resistance training (RT) on high-speed strength is presently unknown. We sought to examine the effects of four weeks of RT combined with time-restricted eating (TRE) vs. regular diet, on fat and fat-free massas well as maximum and explosive force production in healthy, trained participants (18 males, aged 23.7±2.6 years).

METHODS: The order of dieting was randomized and counterbalanced, and the participants served as their own controls. TRE involved an 8-h eating window and non-TRE involved a regular meal pattern. Participants completed performance strength tests (lower and upper body) and body composition scans at baseline and post-intervention. The participants followed a structured full-body RT routine during each dietary intervention (4 sets of maximum repetitions at 85% 1RM in 5 dynamic exercises, 3 times/week). Analysis of covariance (controlling for baseline values) was used for determining differences between both interventions.

RESULTS: Both interventions elicited deceases in fat mass ($p<0.05$), but not in fat-free mass. After training (controlling for baseline values as covariates), non-TRE was compatible with better lower-body jump performance than TRE (SJ peak force, CMJ peak force and CMJ height) ($p<0.05$). Conversely, training with TRE elicited higher values of peak force and dynamic strength index at the level of the upper-body ($p<0.05$).

CONCLUSION: It can be concluded that, when combined with RT, four weeks of TRE do not offer any benefit over a regular dietary pattern for improving fat or fat-free mass in already trained young males. In addition, while the combination of TRE and RT might be beneficial for individuals focusing on developing high-speed strength performance at the upper-body level, the exact opposite is applicable to those focusing on the training the lower-body.

THE EFFECT OF STATIC STRETCHING ON ILIOTIBIAL BAND STIFFNESS AND PATELLAR ALIGNMENT IN HEALTHY INDIVIDUALS

YAGI, M., TANIGUCHI, M., ASAYAMA, A., KOBAYASHI, K., ITSUDA, H., ICHIHASHI, N.
KYOTO UNIVERSITY

INTRODUCTION: The risk factors for patellofemoral joint pain are excessive lateral tilt and shift of the patella in the extended knee position [Drew et al. 2016]. These patellar malalignments are influenced by the tension of the soft tissues attached to the lateral aspect of the patella, particularly the iliotibial band (ITB) [Herrington et al. 2012]. Static stretching (SS) is a common therapeutic intervention to reduce ITB stiffness and improve patellar malalignments [Pourahmadi et al. 2016]; however, it has not been confirmed whether SS could improve ITB stiffness and patellar alignments. Therefore, this study aimed to examine whether SS could reduce ITB stiffness and change patellar alignment in healthy individuals.

METHODS: Seventeen healthy young males participated (23.8±3.8 years), and patellar alignment and ITB stiffness were assessed on their dominant leg before and after a 5-minute SS. The SS was performed in the supine position with 90° knee flexion, maximal hip extension, and maximal hip adduction. One examiner fixed the pelvis, and the other performed the SS. In addition, the participant held the contralateral lower extremity in a maximum hip flexion position to fix the pelvis. The patellar positions relative to the medial and lateral femoral condyles were captured three times each using B-mode ultrasound. Indicators of lateral tilt and shift of the patella were calculated following the same procedures as our previous study. In addition, the shear wave velocity of the ITB was measured twice by ultrasound shear wave elastography as an indicator of the ITB stiffness. Patellar alignment and shear wave velocity were measured at two postures, 5° knee flexion with 0° or 70° hip flexion. A paired t-test was used to compare shear wave velocity and indicators of lateral tilt and shift of the patella before and after SS for each measurement posture, with a significance level set at 5%.

RESULTS: In both measurement postures, the shear wave velocity of the ITB decreased significantly after SS (at 0° hip flexion, 12.2±1.5→10.3±1.6m/s, $p<0.01$; at 70° hip flexion, 9.8±1.8→8.7±1.5m/s, $p<0.01$). In addition, indicators of lateral patellar tilt decreased after SS in both postures (at 0° hip flexion, 2.0±0.5→1.8±0.4., $p<0.01$; at 70° hip flexion, 2.0±0.5→1.8±0.4., $p<0.01$). Furthermore, indicators of lateral patellar shift decreased after SS stretching in both postures (at 0° hip flexion, 34.1±9.0→28.7±7.2°, $p<0.01$; at 70° hip flexion, 31.5±8.4→26.8±7.1°, $p<0.01$). These findings indicated a reduction in lateral tilt and lateral shift of the patella.

CONCLUSION: In healthy individuals, 5-minute SS reduced not only ITB stiffness but also lateral tilt and shift of the patella. The results suggest that SS may be a useful therapeutic intervention to improve ITB stiffness and patellar malalignments.

BIOMECHANICAL RESPONSE TO ACUTE STATIC STRETCHING IN BALLET DANCERS AND NON-DANCERS

MIZUNO, T., OKAMOTO, H.
NAGOYA UNIVERSITY

INTRODUCTION: Increased range of motion after static stretching is attributed to decreased passive torque and/or stiffness and increased stretch tolerance [1]. More flexible individuals, such as ballet dancers, have less passive torque and/or stiffness and greater stretch tolerance than normal or less flexible individuals [2, 3]. Therefore, ballet dancers may have smaller changes in stiffness and stretch tolerance due to static stretching. The purpose of this study was to examine the acute effects of static stretching on range of motion, stiffness, stretch tolerance, and muscle strength for ballet dancers and non-dancers.

METHODS: Thirteen female ballet dancers with at least 5 years of ballet experience were compared to a control group of 13 female university students with no exercise habits. After measuring the muscle thickness of the medial head of the gastrocnemius muscle and Achilles tendon thickness of the right lower limb, passive dorsiflexion measurements of the right lower limb were performed before and after 5 minutes of static stretching. Maximal dorsiflexion angle, passive torque, and deformation of the muscle-tendon junction were measured during the passive dorsiflexion test which the right ankle joint was passively dorsiflexed at 1°/s. The relative stretching intensity was calculated by dividing the angle of the stretching board (absolute stretching intensity) by the angle of maximum dorsiflexion angle. After completion of the measurement on the right lower limb, ankle maximal voluntary plantar flexion torque on the left leg was measured before and after 5 minutes of static stretching to the left leg.

RESULTS: The present study revealed that gastrocnemius muscle thickness was higher in ballet dancers, whereas there was no significant difference in Achilles tendon thickness. Although there was no significant difference in absolute stretching intensity, the relative stretching intensity was higher in the control group than in the ballet dancers. Static stretching increased the maximum dorsiflexion angle, maximum passive torque, and maximum deformation of the muscle-tendon junction in both groups, while submaximal passive torque and maximal plantar flexion torque decreased. However, there was no difference in the amount of change in any of the measures between the ballet dancers and the control group.

CONCLUSION: These results indicate that there is no difference in the effect of 5 min static stretching between the ballet dancer and the control groups.

EFFECT OF DIFFERENT TYPES OF AEROBIC EXERCISE ON HUNGER, FOOD CHOICES, AND AD LIBITUM POST-EXERCISE FOOD INTAKE

HÖCHSMANN, C., LEßMANN, M., RENNER, J., KOEHLER, K.

TECHNICAL UNIVERSITY OF MUNICH

INTRODUCTION: Exercise modulates, hunger, food choices, and energy intake both acutely and chronically. However, these effects are highly variable and are affected by both individual characteristics and exercise-dependent factors (i.e., intensity, duration). It is unknown if the effects on hunger, food choices, and energy intake differ by type of aerobic exercise. Therefore, the present study aimed to investigate the acute effects of duration- and energy expenditure (EE)-matched running vs. cycling on subjective hunger and hypothetical food choices before and after exercise as well as on post-exercise food intake.

METHODS: In a three-way crossover study, eight healthy participants (24.0±2.1 years, 21.2±1.4 kg/m2, 5 women) completed three exercise conditions at 60% VO2peak in randomized order and on separate days following a standardized breakfast: (1) 45min bike ergometer (Bike), (2) 45min treadmill running (Run), (3) and bike ergometer until reaching EE of Run (Bike_adusted). Before (pre), immediately after (post), and 30min after (post30) each condition, participants rated their subjective hunger (condensed visual analog scale from 0 to 10) and hypothetical food amount preferences for both immediate and delayed (+4h) consumption via electronic questionnaires with visual food cues. Additionally, 30min after each condition, participants completed a single-item (cheese pizza) ad libitum test meal.

RESULTS: EE during the exercise sessions was 492±114 (Bike) and 479±96 (Run and Bike_Adjusted). Food intake during the post-exercise test meal (Bike: 1134±419 kcal vs. Run: 1112±495 kcal vs. Bike_adjusted: 1162±486 kcal) did not differ between conditions (p=0.98). Similarly, changes in subjective hunger ratings from pre to post (Bike: −0.1±1.6 vs. Run: 0.5±1.6 vs. Bike_adjusted: 0.8±1.3; p=0.51) and pre to post30 (Bike: 1.0±2.1 vs. Run: 1.4±1.4 vs. Bike_adjusted: 2.3±2.4; p=0.47) did not differ between conditions. Changes in food amount preferences for immediate consumption did not differ between conditions from pre to post (Bike: 16±67 kcal [+7%] vs. Run: 52±58 kcal [+25%] vs. Bike_adjusted: 56±70 kcal [+26%]; p=0.43) or from pre to post30 (Bike: 68±86 kcal [+29%] vs. Run: 112±91 kcal [+52%] vs. Bike_adjusted: 113±102 kcal [+52%]; p=0.55). Likewise, changes in the amount selected for delayed consumption did not differ between conditions at any time point (all p≥0.78). The proportion of food selected for immediate vs. delayed consumption was significantly greater at post30 compared to pre (80±21% vs. 45±31%, p=0.03) only in Bike_adjusted. For all other conditions and time points, intertemporal food preferences did not differ (all p≥0.08).

CONCLUSION: Our results suggest that subjective hunger and ad libitum post-exercise food intake do not differ between acute bouts of duration- and EE-matched running and cycling. There may be differences in intertemporal food preferences, though more research with larger samples is needed to corroborate these findings and explore more longitudinal effects.

IS PICKLEBALL A VALUABLE ACTIVITY FOR PREMENOPAUSAL/MENOPAUSAL WOMEN TO MAINTAIN GRIP STRENGTH?

FIAUD, V., SHIM, A.

WEST TEXAS A&M UNIVERSITY, COLLEGE OF SAINT MARY

INTRODUCTION: Menopause is a critical time for women with heightened risks related to musculoskeletal health. Growing evidence suggests that objective measures of physical performance such as grip strength not only accurately describe physical capability but also act as indicators of current and future musculoskeletal health [1]. Kurina et al. highlighted the decreased in grip strength in post-menopausal women [2]. Pickleball is a fast-growing sport in the US that combines great physical activity with entertainment. The popularity of the sport has sky rocketed, during the COVID crisis among the 55 years old and older, reaching about a third (32.7%) of 65-plus. This study investigated the grip strength of pre-menopausal and menopausal women engaging in pickleball in a rural setting.

METHODS: 17 Women (63.76±8.45 years) from a Southwest US rural area were recruited for this study. All participants were healthy with no injuries within the last 3 months. All participants reported playing pickleball regularly during the week (Mean=326.5min/week). Participants were tested on bilateral grip strength. Hand dominance as well as years of pickleball play were collected. Grip strength was measured according to the standard arm position as recommended by the American Society of Hand Therapists [3] using a hand dynamometer. Maximal effort was expected in each 3 trials of the test for each hand. The results were compared to the normative value for their age range.

RESULTS: An one sample t-test between the dominant hand grip strength and the age/gender normative data showed a significant difference (t(25)=2.059, p=0.001). The non-dominant hand grip strength, when compared to the normative data

showed a significant difference as well (t(27) =2.051, p<0.001). A paired t-test between the dominant and non-dominant grip benefits recorded no significant differences (t(16)=0.368, p<1.746). A large effect was detected (Hedges g=1.22).

CONCLUSION: This study investigated the grip strength of pre-menopausal/menopausal women engaging in the sport of pickleball. Significant greater grip strength was recorded in the dominant as well as non-dominant hands in that population compared to the normative data. This could suggest that the involvement in pickleball may provide a way for older women to increase or maintain their grip strength, thus display better musculoskeletal health.

EFFECTS OF COMBINING MICROCURRENT THERAPY WITH RESISTANCE EXERCISES ON BODY COMPOSITION IN MIDDLE-AGED ADULTS: A PILOT STUDY

LAZA-CAGIGAS, R., KOLIMECHKOV, S., SEIJO, M., SWAINE, I., THIRKELL, J., COLADO, J.C., LARUMBE-ZABALA, E., NACLERIO, F.

UNIVERSITY OF GREENWICH

INTRODUCTION: Microcurrent therapy (MT) is a non-invasive treatment modality that transmits extremely small currents (<1 mA) through the skin. It has been shown that MT can maximise training outcomes when combined with resistance exercise.

METHODS: This study involves a double blind randomised controlled design. Eight participants (mean ± SD: BMI 23.1 ± 3.8 kg/m2, age 54.4 ± 7.4 years, height 168.7 ± 12.3 cm) were randomly assigned to either microcurrent (MC, n = 4) or sham (SH, n = 4) groups (1 male and 3 females per group). After completing two in-person supervised resistance training familiarisation sessions, the participants performed a 6-week home-based resistance exercise programme using resistance bands. Participants were provided with a pre-recorded copy of the session and were asked to perform 2 weekly sessions. The programme involved 8 multi-joint and single-joint exercises targeting the whole-body musculature (squat with shoulder press, biceps curl, squat, lateral pull down, deadlift, triceps extension, lunge, and upright row). Participants were required to perform 3 sets of 12-15 repetitions per exercise with 1.5 to 2 min rest between sets. The rating of perceived exertion (RPE) was determined by the OMNI-Resistance Exercise Scale (OMNI-RES) for elastic bands (0-10 scale) to determine the increasement of the training load over the intervention period. Participants wore a microcurrent or a sham device for 3-h post-workout and in the morning on non-training days. The microcurrent was delivered at a frequency of 1.03 kHz, at an intensity between 50 and 400 μA in a ratio of 2:1 (on:off), to induce a flow of electrons into the tissue. Measurements (body mass, BMI, waist circumference, and percent (%) body fat) were taken pre- and post-intervention. Body composition was determined using air displacement plethysmography (BodPod). Raw changes in all dependent variables were calculated by subtracting pre- from post-intervention values and compared to examine effect sizes.

RESULTS: Neither the MC, nor SH groups showed statistically significant differences for any of the analysed variables: body mass (mean change ± SD; MC = -0.70 ± 1.36 vs. SH = 0.48 ± 1.13 kg, p = 0.233, d = 0.937), BMI (MC = -0.20 ± 0.42 vs. SH = 0.13 ± 0.41 kg/m2, p = 0.313, d = 0.778), waist circumference (MC = -1.45 ± 1.37 vs. SH = -1.30 ± 3.02 cm, p = 0.931, d = 0.064), and % body fat (MC = -1.90 ± 2.96 vs. SH = -0.35 ± 3.82 %, p = 0.545, d = 0.453). However, the analysis of the effects size (d) showed more favourable changes for MC compared to SH.

CONCLUSION: Adding a 3-hr microcurrent therapy post resistance training programme may provide further improvements in body composition in middle-aged adults.

CP-AP10 Fatigue

EXPERIMENTAL TESTING OF METHODS TO MONITOR FATIGUE AMONGST ROYAL NAVY CLEARANCE DIVERS

HOUGH, P.1, COAKLEY, S.2, VINE, C.3, BLACKER, S.3, MYERS, S.3, MARONI, T.3, SIDDALL, A.3, PATTERSON, S.2, CHILLINGSWORTH, K.4, JONES, M.4, STANLEY, N.5, HALSON, S.6, EMMERSON, P.7, PEDLAR, C.2

1. OXFORD BROOKES UNIVERSITY

INTRODUCTION: Chronic sleep restriction (SR) contributes to fatigue and impairs performance. To reduce human error, maximise safety, and optimise performance, Defence and Security organisations require reliable fatigue monitoring methods to identify fatigued individuals. This exploratory study investigated the use of the psychomotor vigilance test (PVT), oculography, and a subjective fatigue rating to identify fatigue amongst Royal Navy Clearance Divers (RN-CD) during a training course, which replicated certain operational demands, including SR.

METHODS: Seven male trainee RN-CDs (mean ± SD; age 29 ± 3 y; height 1.82 ± 0.06 m; body mass 81.8 ± 4.8 kg) undertook two consecutive, 5-day (Monday-Friday) scheduled phases of the RN-CD training course. A typical week (CON) was followed by a high fatigue (HF) week. Sleep was monitored throughout using actigraphy. Fatigue measures were recorded twice daily (AM and PM) using the 10-minute PVT (PVT-10), oculography tests (horizontal precision, tangential variance test, and radial variability), and the Samn-Perelli fatigue scale (SPFS). All dependent variables between CON and HF were compared using a paired samples t-test. Additionally, fatigue thresholds were calculated at a group level (using the 75th percentile above the baseline median) and individual level (1 SD above the baseline mean). These thresholds were used to classify observations as 'fatigued' or 'non-fatigued' (binary outcome) for each variable and participant.

RESULTS: Mean sleep duration was longer during CON (303 ±71 minutes) versus the HF (217 ± 39 minutes) week ($p < 0.001$). Median PVT-10 lapses (CON 1.0 vs HF 3.0) and median reaction times (CON 270.5 ms vs HF 309.5 ms) increased between CON and HF conditions ($p < 0.001$), with no difference in false starts ($p = 0.243$). Fatigue (75th percentile above baseline median) was detected most frequently by reaction time (43 of 63 test results), followed by lapses (35 of 63 test results). Group level subjective fatigue ratings were significantly different between CON (2.5) and HF (3.5) conditions (<0.001). Oculography variables were not different between CON and HF weeks (Radial: p=0.395; Tangential: p=0.667; Horizontal: p=0.144).

CONCLUSION: This exploratory study indicates that PVT-10 derived reaction times were most responsive to sleep loss, and were more likely to classify a participant as fatigued compared to oculography measures and subjective ratings. Further data are needed to support these findings.

THE ASSOCIATION BETWEEN SLEEP AND PERFORMANCE IN FEMALE ATHLETES: A SYSTEMATIC REVIEW

MCGEEVER, A., MALLON, N., DOHERTY, R., BRUINVELS, G., PEDLAR, C.R., VAN SOMEREN, K.A.

ATLANTIC TECHNOLOGICAL UNIVERSITY

INTRODUCTION: Sleep is fundamental to health and recovery and inextricably linked to sports performance. Females may have a different subjective sleep quality to men, as well as potential barriers to optimal sleep such as menstrual cycle (MC) symptomology. The aim of this study was to systematically review the existing literature examining the association between sleep and performance parameters in female athletes.

METHODS: The protocol for this review was registered on PROSPERO (CRD42022297974). Peer-reviewed studies were systematically searched via PubMed, and Web of Science, from inception up to September 2022. Studies had to contain primary data and examine any relationship between sleep and performance in female athletes over the age of 18 years and with their level of competition described.

RESULTS: The search returned 3007 records. After inclusion and exclusion criteria were applied, thirty-two studies remained for review. These studies were separated into four categories: sport-specific performance; cognitive performance; physical performance, readiness and availability; and mood and wellbeing. Only two studies were of high-quality according to a modified Newcastle-Ottawa Scale, indicating a lack of high-quality evidence in the reviewed literature. Lack of control for sleep, athletic population and MC phase or hormonal contraceptive use in females was particularly apparent. The majority of selected studies examined physical performance, readiness and availability, whereas cognitive performance was the least studied aspect of performance.

CONCLUSION: This review highlights that lower sleep duration and/or quality has a detrimental impact on sport-specific performance; cognitive performance; physical performance, readiness and availability; and mood and wellbeing of female athletes. However, high-quality research is needed to describe sufficiently the relationship between sleep and performance in female athletes. Researchers must ensure that study in this area is of methodological suitability for the examination of female athletes and is of an appropriate study duration to account for both chronic sleep as well as physiological processes unique to females such as the MC.

EFFECT OF MMP3 GENE POLYMORPHISM AND SEX DIFFERENCE ON RATE OF RECOVERY OF MAXIMAL VOLUNTARY MUSCLE CONTRACTION TORQUE AFTER ECCENTRIC EXERCISE

DEGUCHI, M., HOMMA, H., INOGUCHI, T., KOZUMA, A., SAITO, M., SAITO, A., NAITO, T., TSUCHIYA, Y., KOUZAKI, K., OCHI, E., OKAMOTO, T., NAKAZATO, K., KIKUCHI, N.

GRADUATE SCHOOL OF NIPPON SPORTS SCIENCE UNIVERSITY

INTRODUCTION: Muscle damage due to maximal eccentric exercise can result in reduced muscle strength (Chen and Li, 2020). Recently, it has been reported that muscle strength after eccentric exercise is influenced by sex and genetic factors (Baumert et al., 2016, Sewright et al., 2008). Matrix metalloproteinase 3 (MMP3) gene polymorphisms, whose expression is affected by sex, are among the polymorphisms associated with reduced muscle strength due to muscle damage (Fang et al., 2007). The aim of this study was to investigate the effect of MMP3 gene polymorphism and sex differences on muscle strength after eccentric exercise.

METHODS: A total of 101 participants, including 52 men (age: 22.8 ± 2.9 years, height: 171.2 ± 5.5 cm, weight: 67.8± 9.8 kg) and 49 women (age: 21.6 ± 1.6 years, height 160.4 ± 5.6 cm, weight: 56.2 ± 6.4 kg), who had not previously participated in daily biceps resistance exercise were enrolled in the study. Participants performed five sets of six maximal eccentric elbow flexion exercises in the non-dominant arm. Maximum voluntary contraction (MVC), range of motion (ROM), muscle soreness, and serum creatine kinase (CK) concentration were assessed immediately before and after, as well as 1, 2, 3, and 5 days after, eccentric exercise. The recovery rate of MVC was calculated by subtracting the %MVC measured imme-

diately after exercise from the %MVC measured on day 5 after exercise. MVC, ROM, muscle soreness and CK over time were compared groups between genotype and sex by a two-way repeated measure analysis of covariance (ANCOVA)with %MVC at immediately as a covariate.

RESULTS: There was no difference between males and females in the change in MVC torque after exercise (p = 0.945). We found significant MMP3 polymorphism - sex interaction in the recovery rate of MVC at 5 days after exercise between two genotype groups in men and women (p = 0.026). G-allele carriers in men had significantly lower recovery rates of MVC (p = 0.041) after exercise. On the other hands, there was no significant difference in women. There was no significant genotype – sex interaction in CK, ROM and muscle soreness.

CONCLUSION: In the present study, MMP3 polymorphism - sex interaction was found to correlate with the recovery rate of MVC, particularly, in men.

TAKING THE HORIZONTAL FORCE COMPONENT OF THE 90:20 IPC TEST INTO ACCOUNT INCREASES SENSITIVITY TO DETECT MUSCLE FATIGUE OF THE POSTERIOR CHAIN, AND LIMB ASYMMETRIES.

RASP, D.M., PATERNOSTER, F.K., HANIKA, F., SCHWIRTZ, A.

TECHNICAL UNIVERSITY OF MUNICH

INTRODUCTION: Lateral deficit and fatigue [1] favor the risk of hamstring strain and can increase the risk of ACL ruptures. Instead of using high-end methods like an isokinetic device, recent literature shows that tests like the 90:20 isometric peak force (IPF) test of the posterior chain (PC) [2] are alternatives to detect e.g. muscle fatigue by just using a regular force plate. A possible problem associated with these tests is that only the vertical component (Fz) is considered for data analysis. Different pushing techniques can result in meaningful posterior-anterior forces (Fx), leading to wrong conclusions due to an underrepresentation of the PC capabilities. Therefore, the aim of this study is to evaluate if the resultant force (Fx+Fz = Fres) of the posterior force component shows an increased sensitivity to detect muscle fatigue and limb symmetries of the PC using the 90:20 test.

METHODS: The IPF of 16 subjects from a semi-professional soccer team was measured 1 h prior to a soccer match and repeated immediately after the match or their substitution, respectively. For the measurements, subjects stood against a wall and placed one leg (randomized order) with the heel onto a force plate (1000Hz), placed on a height adjustable table. Hence hip and knee joints were flexed to 90° and 20°, respectively, as proposed by [2]. First, subjects' leg weight was measured to account for gravitational forces. Second, participants were then asked to apply force as quickly and hard as possible onto the force plate for 5 s using two different verbal instructions which were randomized:

1: "Press as hard as you can onto the force plate."

2: "Press as hard as you can onto the force plate and pull it towards you."

They carried out the procedure with the other leg and made a total of two trials of IPF with each leg with 30 s break between trials. Then, they carried out the same procedure under the other instruction. Unlike [2], not only peak Fz was analyzed but also the peak resultant force. In addition, limb asymmetries were calculated from both analysis procedures. Paired samples t-tests (alpha = 0.05) evaluated the sensitivity (= ES [Cohen's d]) of the Fz and Fres pre vs. post-match and the respective limb asymmetries.

RESULTS: Due to the postponement of the soccer club's match schedule, data acquisition took place four days after the submission deadline of this abstract on February 18th. However, piloting (n = 4) shows a larger effect size of the peak Fres (d = -0,58) compared to the peak Fz (d = -0,42). On top of that, peak Fres detects an increased limb asymmetry compared to only using Fz (d = 0,32 or 11.3 %).

CONCLUSION: Piloting results show that using Fres in combination with verbal instruction 2 gives a better representation of the PC capabilities. Hence using such a setup might lead to an increased sensitivity in terms of detecting risk factors associated with hamstring strain injuries.

ASSESSING INDICES OF AEROBIC FITNESS WITH DETRENDED FLUCTUATION ANALYSIS OF HEART RATE VARIABILITY DATA

AJAYI, O.O., VAN RASSEL, C.R., DOMINGUEZ, E., JORDAN, M., MACINNIS, M.J.

UNIVERSITY OF CALGARY

INTRODUCTION: Accurate identification of the gas exchange threshold (GET) and the respiratory compensation point (RCP) is important for effective exercise prescription and fitness assessment [1]. Categorized into one of three intensity domains, the GET and RCP can be used to separate moderate from heavy exercise intensities, and heavy from severe exercise intensities, respectively. Recently, a non-linear measure of heart rate (HR) variability (HRV), known as detrended fluctuation analysis (DFA a1), emerged as a tool to identify exercise thresholds, where DFA a1 values of 0.75 and 0.5 reportedly represent GET and RCP, respectively [2]. The aims of this study were to i) assess the suitability of DFA a1 values of 0.75 and 0.5 to evaluate GET and RCP, (ii) evaluate possible sex differences in DFA a1 threshold values, and iii) determine whether DFA a1 values during low-intensity exercise can predict aerobic fitness.

METHODS: Twelve (6M, 6F, 31±9 yrs) recreationally active participants performed 10-min of cycling at 75W followed by a 25W/min ramp incremental test until failure to determine GET, RCP, and VO2max. RR intervals (H10; Polar Electro Oy, Kempele, Finland) were recorded continuously during the exercise trial. RR data were preprocessed prior to quantifying DFA a1 using a modified Python script [3]. DFA a1 measurements at GET and RCP were compared to reported threshold

values of 0.75 and 0.5, respectively, using dependent sample t-tests. DFA a1 measures at GET and RCP were compared between males and females using independent sample t-tests. Correlations were performed between DFA a1 values between minute 7-9 at 75W and absolute VO2max values. Statistical significance was set at $p<0.05$.

RESULTS: DFA a1 values at GET (1.28±0.43) and RCP (0.79±0.39) were significantly different from 0.75 (t=3.879, p=0.004, n=10) and 0.5 (t=2.370, p=0.04, n=10) respectively. At GET, DFA a1 values were not significantly different between males (1.39±0.45) and females (1.18±0.44, p=0.48). At RCP, DFA a1 values were also not significantly different between males (0.93±0.52) and females (0.66±0.16, p=0.30). When normalized to fat free mass (FFM), VO2max was not different between males (58.7±7.8 ml/kg FFM/min) and females (56.6±13.3 ml/kg FFM/min, p=0.75). The correlation between DFA a1 values and absolute VO2max was not significant (r=-0.15, p=0.65).

CONCLUSION: Despite previous studies reporting that DFA a1 may be useful to measure exercise thresholds, our data suggest that DFA a1 values of 0.75 and 0.5 do not coincide with GET or RCP. Therefore, the proposed DFA a1 threshold values may not properly demarcate the exercise intensity domains. Additionally, there were no sex differences found with DFA a1 threshold values. Lastly, DFA a1 at a moderate exercise intensity was not a strong predictor of aerobic capacity.

RATING OF PERCEIVED EFFORT BUT RELATIVE TO WHAT? A COMPARISON BETWEEN IMPOSED AND SELF-SELECTED ANCHORS

MALLERON, Y.1,2, IHAR-NIR, I.1,2, VIGOTSKY, A.D.3, HALPERIN, I.1,2

1,2 TEL AVIV UNIVERSITY, TEL AVIV, ISRAEL; 3 NORTHWESTERN UNIVERSITY, EVANSTON, USA

INTRODUCTION: Collecting reliable and valid rating of perceived effort (RPE) data requires properly anchoring the scales' upper limits (i.e., the meaning of 10 on a 0–10 scale). Yet, despite their importance, anchoring procedures remain understudied and theoretically underdeveloped. Here we propose a new task-based anchoring procedure that distinguishes between imposed and self-selected anchors. In the former, researchers impose on participants a specific task as the anchor; in the latter, participants choose the most effortful task experienced or imaginable as the anchor. We compared the impact of these conceptually different anchoring procedures on RPE.

METHODS: Twenty-five resistance-trained participants (13 females) attended a familiarization and two randomized experimental sessions. In both experimental sessions, participants performed non-fatiguing and fatiguing isometric maximal voluntary contraction (MVC) protocols with the squat followed by the gripper or vice versa. After each MVC, participants reported their RPE on a 0–10 scale relative to an imposed anchor of the performed task (e.g., gripper MVCs anchored to a gripper MVC) or to a self-selected anchor.

RESULTS: In the non-fatiguing condition, imposed anchors yielded greater RPEs than self-selected anchors for both the squat [on average, 9.4 vs. 5.5; Δ(CI95%) = 3.9 (3.2, 4.5)] and gripper [9.4 vs. 3.9; Δ = 5.5 (4.7, 6.3)]. Similar results were observed in the fatiguing condition for both the squat [9.7 vs. 6.9; Δ = 2.8 (2.1, 3.5)] and gripper [9.7 vs. 4.5; Δ = 5.2 (4.3, 5.9)].

CONCLUSION: We found large differences in RPE between the two anchors, independent of exercises and fatigue state. These findings provide a basis for further development and refinement of anchoring procedures and highlight the importance of selecting, justifying, and consistently applying the chosen anchors.

PLAYING POSITION EFFECTS ON BIOMARKERS IN MALE FUTSAL PLAYERS

KALIARNTAS, K.1, SOUGLIS, A.2, ANDRONIKOS, G.1, APOSTOLIDIS, A.2, GELADAS, N.2, TRAVLOS, A.3, BOGDANIS, G.2

<1> EDINBURGH NAPIER UNIVERSITY, EDINBURGH, UK <2> NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS, ATHENS, GREECE <3> UNIVERSITY OF PELOPONNESE, GREECE

INTRODUCTION: Currently, studies focusing on the effects of playing position in futsal (five-a-side indoors soccer) are limited, while there is sparsity of information regarding inflammatory and antioxidant responses. The aim of the current study was to investigate the effects of playing position on the time-course of oxidative stress, muscle damage markers, as well as inflammatory and antioxidant responses for a period of five days following a futsal match.

METHODS: Sixty-two futsal players were randomly allocated into four groups: control group (n=16, age: 23.6±0.7 y), wingers (n=18, age: 23.1±0.5 y), defenders (n=16, age: 22.4±0.4 y) and pivots (n=12, age: 24.1±0.5 y). The following variables were measured before, immediately after, and 24h, 48h, 72h, 96h, 120h, and 144h post-match: creatine kinase (CK), lactate dehydrogenase (LDH), interleukin-6, (IL-6), tumor necrosis factor alpha (TNF-a), complete white blood cell count (WBC), C-reactive protein (CRP), Fibrinogen (FIB), soluble vascular cell adhesion molecule-1 (sVCAM-1), sP-Selectine, thiobarbituric acid reactive substances (TBARS), protein carbonyls (PC), Uric Acid (UA), oxidised glutathione (GSSG) and catalase (CAT). A two-way mixed ANOVA was used for all dependent variables.

RESULTS: CK and plasma LDH peaked at 24h and remained elevated for 144h and 96h respectively in all active groups. LDH remained elevated for 120h in defenders and 144h in wingers. IL-6 and TNF-a peaked immediately after and returned to baseline at 24h in all groups apart from wingers where IL-6 returned to baseline levels at 48h. WBC count peaked immediately after and returned to baseline at 48h in defenders and pivots and at 96h in wingers respectively. CRP and fibrinogen peaked at 24h and returned to baseline at 72h in most groups. CRP and FIB returned to baseline at 96h in wingers, whereas in pivots it returned to baseline much faster (48h). sVCAM-1 peaked at 24h and returned to baseline at

72h in all groups, whereas sP-Selectine peaked immediately after and returned to baseline at 72h, apart from the wingers group that returned to baseline levels at 96h. Both TBARS and PC peaked at 24h and retuned to baseline levels at 120h post-match. GSSG peaked at 24h and returned to baseline at 96h in all groups whereas CAT peaked immediately after and returned to baseline at 48h post-match. UA peaked at 24h and remained elevated 120h for Wingers and defenders and 96h post-match for pivots respectively.

CONCLUSION: Immediate and short-term changes are induced by a single futsal match on oxidative, inflammatory, muscle damage and antioxidant markers. The magnitude and time-course of these changes depend on playing position, with wingers showing the greater responses. These findings may be used to assist recovery practices and to prescribe appropriate training following intense futsal games.

PUPILLOMETRY: DETECTION OF VARIATIONS IN AUTONOMIC NERVOUS SYSTEM ACTIVITY IN HIGH LEVEL YOUNG ATHLETE.

GIOVANNANGELI, C.1,2, BORRANI, F.3, BROUSSOULOUX, O.4, CANDAU, R.1

1UNIVERSITY OF MONTPELLIER; 2SPORT AND YOUTH CENTER OF CORSICA; 3UNIVERSITY OF LAUSANNE; 4UNIVERSITY PASQUALE PAOLI, CORTE

INTRODUCTION: The pupil light reflex (PLR) is a reliable physiological mechanism which lasts 3.5 seconds [1]. It's based on a strength equilibrium mathematical model whose fitting with real data is almost perfect. These components are viscous, elastic, sympathetic and parasympathetic [2]. The autonomic nervous system (ANS) activity is commonly modulated with clinostatism and orthostatism positions. These ones are used to appreciate activity variations through the monitoring of heart rate variability (HRV) in elite sport [3]. We assume the PLR which reports the ANS activity is susceptible to being impacted by these positions and could complete HRV analysis.

METHODS: Seventeen subjects, handball and basketball players (respectively n=10, n=7), aged 16±0.87, who were in a pathway to high level access were exposed to light flashes which were produced using a screen (Samsung QB50R LED, 50 inchs - Vietnam). Subjects wore glasses equipped with two cameras (Pupil core by Pupil Labs – Berlin, Germany) to record PLR at 120hz sampling frequency. Ten flashes lasting 200ms, interspaced by 30 seconds, were produced in each position with a 2 minute rest period before the beginning of each analysis. Throughout the whole protocol, athletes wore a cardiofrequencemeter (Polar H9 by Polar - Malaysia) to collect HRV data. A principal component analysis was done to characterize the nature of the data given by pupillometry and HRV respectively. Student paired T tests were done after application conditions were verified to appreciate the PLR sensitivity and its model of the study [2] at changing positions. Significance was set at $P<0.05$.

RESULTS: The model showed a high quality degree of fit with the measured PLR ($r2=0.99\pm0.01$). In clinostatic condition, the basal pupil diameter was significantly smaller than in orthostatic condition ($p=0.002$). The constriction has a shorter duration and the parasympathetic strength was reduced (respectively $p=1.25*10-11$, $p=0.03$) in clinostatic condition compared to in orthostatic. The redilation and the concomitant impulse of both sympathetic and parasympathetic systems were significantly higher compared to in clinostatic condition (respectively $p = 1.03*10-7$, $p = 0.03$). The principal component analysis showed that information given by pupillometry and HRV analysis were distinct and complementary.

CONCLUSION: Raw pupillometric data and those from the tested model appears sensitive to the changing position. Pupillary and cardiovascular responses do not seem redundant but can give complementary information about ANS. The HRV provides information transmitted by baroreceptors while pupillometry would deliver more general indications about ANS state. The pupillometry could constitute a complement to appreciate the ANS state in regard to training load in high level athletes.

SPORTS INJURY SURVEILLANCE PRACTICES AND METHODS IN UNIVERSITY STUDENT-ATHLETES: A SYSTEMATIC REVIEW

SCHIPPERS, R.

THE UNIVERSITY OF THE WESTERN CAPE

INTRODUCTION: Injury surveillance and epidemiology studies are essential components of protecting athletes' health. In recent years, university sports have grown globally in popularity and professionalism. This has been reflected in the continuous increase in student-athlete participation, which has also increased the burden of sports injuries. In general, universities struggle to adequately implement standardized surveillance methods and safety measures within university sports. Therefore, this systematic review aims to identify injury surveillance practices and methods used in the recording and reporting of sports injuries in university student-athletes.

METHODS: Prospective cohort studies investigating sports injuries in university student-athletes were included to identify surveillance methods used for recording and reporting sports injuries. The systematic review methodology was performed per the PRISMA guidelines. Databases (PubMed, SPORTDiscus, Scopus, and Web of Science) from 2000-2022 were

searched for relevant articles. Two reviewers independently selected and screened articles using Covidence open-source software and assessed the risk of bias through the Newcastle Ottawa Scale. Data from the included studies were analyzed descriptively, synthesized, and summarized.

RESULTS: A total of 47 studies were included. Four injury surveillance systems and five injury surveillance guidelines were identified across 31 university sports codes. Three different definitions of injury were used. Student athletic therapists, qualified athletic therapists, athletes, physiotherapists, physicians, and course instructors mostly recorded the data, and the duration of surveillance ranged from one tournament to one university career. The exposure and injury data were recorded either via an electronic web-based system (24 studies) or physical paper (8 studies).

CONCLUSION: This review identified injury surveillance systems and guidelines using a variety of different practices and methods across different university sports codes, including the injury definition, who records the data, and the direct method of data collection. Only one study followed the IOC consensus statements on injury and illness definitions and data collection procedures for use in epidemiological studies in sports. In addition, six studies did utilize sport-specific consensus statements on injury and illness definitions and data collection procedures. Future studies should utilize a consistent definition of sports injuries, qualified medical personnel to record the data, and an electronic web-based system to collect the data. This will enable the development of a standardized methodological strategy for future studies on sports injuries in university student-athletes. This provides a unique opportunity to introduce standardized injury surveillance systems that could lead to a better understanding of sports-related injury and support the implementation of injury prevention measures within university sports.

INJURY PATTERNS IN ELITE GERMAN SOCCER PLAYERS: INJURY HISTORY, TYPOLOGIES, AND IMPLICATIONS

SCHWIETE, C.1, BROICH, H.2,3, MESTER, J.4, WIGGER, U.5, BEHRINGER, M.1

1 GOETHE UNIVERSITY FRANKFURT, DEPARTMENT OF SPORTS SCIENCES, GERMANY 2 FC BAYERN MÜNCHEN AG, DEPT. SCIENCE, PERFORMANCE, FITNESS, MUNICH, GERMANY 3 MEDICAL SCHOOL HAMBURG, DEPT. PERFORMANCE, NEUROSCI

INTRODUCTION: Injuries & infections in soccer are commonly associated with prolonged periods of downtime for players as well as financial costs for clubs. However, the origin and time period of downtime can vary greatly. Among others, muscle injuries have been reported to be a major reason for absence in soccer players. The aim of the present study was to compile the injuries of an elite German soccer club to see if different injury patterns regarding the affected structures can be identified.

METHODS: Total injuries of 49 first league german soccer players (23.6 ± 4.4 years) were collected and analyzed over the course of 14 consecutive seasons (07/08 – 22/23). All presented data were obtained from a publicly accessible database (transfermarkt.de). Injuries were categorized regarding their type (muscle, infect, joint, tendon/ligament, back, others), and days of absence were screened.

RESULTS: In total, 573 injuries occurred, including 183 muscle injuries (31,9%). This accumulated in 13590 days of absence for all players; 2790 days could be attributed to muscle injuries. There was a great variance regarding muscle-related absence, ranging from 0 – 383 total days (mean: 56.5 ± 78.8 days). On average, 16% ± 18.4% of all injuries were muscle-related, with accumulations of up to 65% in individual players.

CONCLUSION: The results of this study show that muscle injuries were a major cause of prolonged periods of absence in the tested elite german soccer players. Furthermore, it appears that both the absolute muscle injuries and the relative distribution among players varies greatly and there may be players who are more susceptible to injuries of a muscular origin than others. Knowledge of such individual injury profiles is important to enable physicians and coaches to manage individual loading to minimize the risk of injury and infections.

PREVALENCE RATES OF SHOULDER AND ELBOW OVERUSE INJURIES AMONG COMPETITIVE OVERHEAD YOUTH ATHLETES IN SINGAPORE

LAU, R., MUKHERJEE, S.

NATIONAL INSTITUTE OF EDUCATION, NANYANG TECHNOLOGICAL UNIVERSITY, SINGAPORE

INTRODUCTION: High prevalence rates of shoulder and elbow overuse injuries have been reported among overhead youth athletes in various populations. However, there is a dearth of such epidemiological evidence among Asian overhead youth athlete populations. Therefore, the aim of this study was to determine the prevalence rates and severity of shoulder and elbow overuse injuries, and its associated factors among competitive overhead youth athletes in Singapore.

METHODS: An online survey was distributed among 532 overhead youth athletes (12- to 18-years old) in Singapore, who were recruited from various youth sports clubs and training centres. Participants' gender, age, years of experience, and weekly training hours were collected. The survey included four multiple-choice questions and one open-ended question. Presence of an overuse injury was determined based on participants' response to Question 1, concerning their ability to participate in training and competition. Severity scores were tabulated from the scores of Questions 1 to 4, which were each scored on a scale of 0-8-17-25. The association between participants' demographics and presence of shoulder and elbow overuse injuries was determined using the Chi-square Test. Crude Odds Ratios and 95% confidence intervals were also calculated.

RESULTS: A total of 434 surveys were found complete and included for analysis. Badminton, cricket, softball, swimming, and volleyball were some of the sports studied. The prevalence rates of shoulder and elbow overuse injuries were 31.3% and 9.2%, respectively. The respective severity scores were 30.4 ± 14.4 and 38.4 ± 22.4. Age was associated with the

presence of both shoulder (P = .016) and elbow overuse injuries (P = .037). Years of experience was associated with the presence of substantial elbow injuries (P = .049). Weekly training hours was associated with the presence of shoulder (P = .016) and substantial shoulder injuries s (P = .020). Being 15- to 18-years old increased the odds of shoulder (OR = 1.65, 95% CI 1.10 to 2.49) and elbow overuse injuries (OR = 2.04, 95% CI 1.03 to 4.01). Having more than 8 years of experience increased the odds of substantial shoulder (OR = 2.71, 95% CI 1.01 to 7.29) and substantial elbow overuse injuries (OR = 3.92, 95% CI 1.01 to 15.24). Training more than 11 hours per week increased the odds of shoulder overuse injuries (OR = 2.64, 95% CI 1.31 to 5.30).

CONCLUSION: Shoulder overuse injuries are more prevalent but elbow injuries tend to be of greater severity among competitive overhead youth athletes in Singapore. Coaches working with older and experienced youth athletes training long hours every week should be cognizant of the risk of shoulder and elbow overuse injuries and consider the implementation of injury prevention programs.

TRAINING LOAD AND INJURIES IN LEINSTER SCHOOLBOY RUGBY PLAYERS; THE SCRUM STUDY

MURPHY, S., KEATING, L., FRENCH, H.

ROYAL COLLEGE OF SURGEONS IN IRELAND

INTRODUCTION: Rugby Union has seen increasing participation worldwide, which in turn increases exposure and potential for sport-specific injuries. Rugby specific reporting procedures provide guidance for injury surveillance research [1]. The management of training loads has been highlighted to help minimize risk of injury [2]. The SCRUm study aimed to investigate training loads and describe injury incident in Leinster schools' senior rugby squads.

METHODS: This prospective cohort study monitored training loads and injuries during a senior schoolboy's rugby season 2019-20. Informed consent and/or assent was obtained from participants and guardians. School nominated personnel recorded injuries (site, mechanism, severity) using the World Rugby Injury Surveillance System (ISS) web-portal. Individual players recorded training load (intensity, type, duration) using The Sports Office app via personal smartphone devices.

RESULTS: 463 participants in 16 schools provided data over 20 weeks (partial season) with rolling recruitment and early end to season due to Covid19 restrictions. 84 injuries were reported (61 match and 23 training). Injury incidence per 1000 player hours was 19.9 (95% CI 152-256) match injuries and 0.7 (95% CI 0.4-1.0) training injuries. Median time loss was 22 days (95% CI 16-27). Most frequent injury sites included shoulder (n=23, 27%), head (n=22, 26%), wrist/hand (n=9, 11%), ankle (n=8, 10%), and knee (n=5, 6%). The tackle was cited in 49% of injuries; tackling (n=25, 30%) and tackled (n=16, 19%). Low player data reporting led to estimated total training exposure of 31141 hours; with schools ranging from 365 to 4879 hours. Match exposure was calculated as 3063 hours: schools ranged from 123 to 385 hours. 500 training sessions were reported, including conditioning (weights, n=155, 31%; non-weights, n=22, 4%), rugby skills (non-contact, n=139, 28%; semi-contact, n=118, 24%; contact, n=54, 11%), and other (n=12, 2%).

CONCLUSION: Match activity and tackle event cited most injuries. Head and shoulder injuries occurred more often, with knee and ankle injuries causing longer time loss. The match injury incidence is lower in comparison to similar schoolboy cohorts; Ulster 29/1000 match hours and Munster/Connacht 54/1000 match hours [3, 4]. Training exposure varies widely across schools. Low player engagement limited individual level data analysis in this cohort.

This research was funded by the Irish Rugby Football Union Charitable Trust.

LACK OF PROPRIOCEPTIVE PLASTICITY IS ASSOCIATED WITH AT-RISK BIOMECHANICS FOR ANTERIOR CRUCIATE LIGAMENT INJURY.

PICOT, B.

SAVOIE MONT-BLANC UNIVERSITY

INTRODUCTION: Anterior cruciate ligament (ACL) injuries are frequent in team sports, especially during side-cutting manoeuvres (1). Altered sensory integration contributes to increased injury risk (2) and several biomechanical determinants have been previously associated with the occurrence of ACL ruptures (3). Recent data has shown that proprioceptive postural control strategies differ between athletes (4), with decreased postural performance and aberrant hamstring recruitment in young individuals with a more ankle-steered proprioceptive strategy. Since postural control during complex tasks requires adequate sensory integration and somaesthetic reweighting (5), we aimed to investigate the relationship between proprioceptive strategies and biomechanics during side-cutting manoeuvres in the context of ACL injuries.

METHODS: 47 handball players performed unanticipated (CUTunant) and unanticipated (CUTunant) cutting tasks. Their ability to reweight somaesthetic signals during postural perturbations on various surfaces was assessed using the centre of pressure displacements generated by the muscle vibration on a firm and foam surface. Two opposing behaviours were observed: a "rigid" strategy in which reliance on ankle proprioception increased on the foam, and a "plastic" strategy that involved a proximal shift of proprioceptive reliance ($p<.001$). Statistical Parametric Mapping analysis was used to compare

pelvic and lower limb side-cutting kinematics, kinetics and electromyography activity from 7 muscles 200ms before and after initial contact (IC) using a two-way Analysis of Variance (strategy×condition).

RESULTS: 20 athletes (11 females and 9 males, 18.5 years) were characterized as plastic and 20 (12 females and 8 males, 18.9 years) as rigid. No interaction between condition and proprioceptive profile was observed. More ipsilateral pelvis inclination prior IC and lower vastus lateralis (VL) activity immediately after IC was observed during CUTant. When comparing proprioceptive strategy, rigid individuals exhibited less pre-activity of the semitendinosus ($p<0.001$) and higher VL activity ($p=0.032$). Conversely, they showed higher gluteus medius pre-activity ($p<0.05$) and higher VL activity 100ms after IC ($p<0.001$). Ankle was also more internally rotated before and during the stance phase ($p<0.05$) among rigid athletes.

CONCLUSION: Lower ST pre-activity, higher foot internal rotation and VL overactivation were previously associated with an increased risk of ACL injury (4). Decreased proprioceptive plasticity is linked with at-risk biomechanics for Anterior Cruciate Ligament injury during side-cutting manoeuvres.

INFLUENCE OF PHYSICAL QUALITIES ON GAME PERFORMANCE, ACUTE PHYSIOLOGICAL RESPONSES AND POST-GAME RECOVERY IN ICE HOCKEY

HAVERINEN, M.1,2, HALONEN, E.1,2, JORDAN, M.3,4, AVELA, J.1,5, PARKKARI, J.1,6, KYRÖLÄINEN, H.1,5

1UNIVERSITY OF JYVÄSKYLÄ; 2VARALA SPORTS INSTITUTE; 3UNIVERSITY OF CALGARY; 4SPORT MEDICINE CENTRE; 5NEUROMUSCULAR RESEARCH CENTER; 6TAMPERE RESEARCH CENTER OF SPORTS MEDICINE

INTRODUCTION: Understanding the effects of physical qualities on game performance, loading and post-game recovery are needed in professional team sports in order to optimize physical training. Despite the growing number of scientific research in ice hockey during the past couple of decades, there is still lack of knowledge in this area. Therefore, the purpose of the present study was to examine the influence of physical qualities on game performance, acute physiological responses and post-game recovery in ice hockey.

METHODS: Thirty-eight male professional ice hockey players (age 26.2 ± 4.6 years; height 181.9 ± 5.9 cm; body mass 85.6 ± 6.5 kg) from two different teams participated in the study. Aerobic (maximal oxygen uptake [VO2max]) and anaerobic (Wingate 30 s peak power [PP]) bicycle ergometer tests were executed during the pre-season five weeks prior to an official ice hockey game played against the teams at the beginning of the regular season of the Finnish Elite League. Neuromuscular performance (countermovement jump [CMJ]), hormonal responses (testosterone [T]; cortisol [C]) and immunological markers (interleukin-10 [IL-10]) were assessed before (pre-9h; pre-2.5h) and after (post-0h; post-12h) the game. During the game, skating volume and intensity were recorded using a Local Positioning System. Players were divided into high- and low-groups based on their level of physical qualities.

RESULTS: VO2max correlated with the skating volume, amount of high intensity skating and repeated high intensity sprints during the game ($r=0.33$-0.44; $p<0.05$). CMJ height increased from pre-9h to post-0h in the lower PP group (5.7%; $p<0.05$), whereas the opposite was found in players with higher PP (-2.2%; $p<0.05$) despite no differences in game load were observed between the groups. The higher PP group maintained CMJ height from post-0h to post-12h, while there appeared a significant reduction in the lower PP group (0.5% vs. -4.4%; $p<0.05$). Additionally, a greater reduction in T:C-ratio and T were noticed immediately after the game compared to the pre-values, and more pronounced recovery 12 hours after the game in players with higher VO2max and PP. Furthermore, IL-10 increased more in the higher VO2max group from pre-9h to post-0h (128% vs. 43%; $p<0.05$) and recovered to a higher extent from post-0h to post-12h (38% vs. 13%; $p<0.05$).

CONCLUSION: Aerobic endurance capabilities and ability to produce high amount of high intensity skating during official ice hockey game appear to be related. In addition, players with well-developed physical qualities, particularly higher aerobic power, seem to generate higher external, hormonal and immunological load during the game but also recover more rapidly after the game. Given the level of physical qualities related to differences in loading and recovery, the individual physical profile should be taken into account when designing physical training for ice hockey players in relation to their playing schedule.

PREDICTION OF MAXIMUM LACTATE CONCENTRATION DURING AN ALL-OUT ANAEROBIC TEST IN ELITE ICE HOCKEY PLAYERS

ALLISSE, M.

UNIVERSITY OF SHERBROOKE

INTRODUCTION: Maximum lactate concentration is an important measure in the development of hockey players and is typically performed using a lactate analyzer. However, this procedure may become cumbersome and costly when attempting to evaluate large groups of hockey players. Thus, the aim of this study was to develop an equation allowing an indirect assessment of the maximum lactate concentration produced from an all-out on-ice skating effort in elite adolescent ice hockey players.

METHODS: Twenty elite male ice hockey players participated in this study (age=15.7±1.0 years). The lactate anaerobic skating test (LAST) consisted of skating back and forth on an 18.2 m (60 ft) course at maximal speed with abrupt stops at each end for a total of 6 shuttles (total distance=218.2 m; average time=52.0±2.0 s). The maximum post-exercise lactate concentration was measured using a Lactate Pro analyzer and heart rate with a Polar chest strap. The variables used to estimate lactate concentration were time (s), heart rate (bpm), number of skating strides during the last shuttle (6th) and the skating stride index (SSI, number of skating strides during the last back and forth shuttle, divided by the average speed (strides/(m/s)) to complete the LAST course).

RESULTS: The average maximum lactate concentration was 14.3 mmol·L-1, which is consistent with the values found in adult elite players. No significant difference was observed in lactate production between younger and older individuals (P=0.248). The regression equation showed a strong correlation (r=0.929) with a standard error in the estimate (SEE) of 0.69 mmol·L-1, indicating an excellent accuracy of the equation. By removing variables directly related to skating efficiency in the lactate prediction equation, the correlation coefficient dropped to r = 0.49 and the SEE increased to 1.5 mmol·L-1, indicating 10.5% SEE that is 117% greater than the SEE obtained with the equation incorporating skating variables. Equation: Lactate (mmol·L-1) = - 161.88 + (Time 218.2 m×3.10) + (stride_6×8.36) + (HR×0.064) + (SSI×-34.51).

CONCLUSION: This study allows coaches to associate a metabolic estimation during an on-ice test that involves the solicitation of the anaerobic lactate system. The inclusion of skating variables significantly improves model accuracy and confirms the relevance of including skating economy variables for estimating maximum lactate level. Its validity and reliability make the prediction equation a tool of choice for noninvasively evaluating the metabolic expenditure of players. The maximum lactate concentration estimation has been automated using an Excel file where only the total time, the number of skate strides during the last shuttle (6th) and the maximum heart rate at the end of the test need to be entered. The estimation of lactate concentration will allow coaches to better target the needs of their elite players and thus improve their specific physical preparation.

PERFORMANCE-DETERMINING VARIABLES OF A FULL SPRINT CROSS-COUNTRY SKIING COMPETITION

SKOVERENG, K.1, KJØSEN TALSNES, R.1, BERDAL, T.1, BRATTEBØ, J.M.1, KOCBACH, J.1, SEEBERG, T.1, LOSNEGARD, T.2, SANDBAKK, Ø.1

1NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY, 2NORWEGIAN SCHOOL OF SPORT SCIENCES

INTRODUCTION: Sprint cross-country skiing involves repeated ~3 min efforts during a ~3-4 h competition, starting with a qualifying time-trial (TT) followed by three subsequent knock-out heats (quarterfinals [QF], semifinals [SF], and final [F]). Although the physiological demands and performance-determining variables of time-trials have been investigated in detail, there exist limited data on how the relationship between performance-determining variables and the different efforts evolve throughout a sprint competition. Therefore, this study investigated lab-derived performance-determining variables and the relationship with performance during a full sprint cross-country skiing competition.

METHODS: Eighteen national-level male junior skiers performed a simulated on-snow sprint competition in the skating technique consisting of an individual TT followed by 3 heats (QF, SF, and F) for a total of four efforts. A promotion-relegation system was used instead of the regular elimination system so that each skier completed all heats. Within ~3 weeks from the competition, the skiers performed laboratory tests of performance and physiological variables in roller-ski skating, including sub-maximal efforts and an incremental test to exhaustion as well as upper- and lower-body strength and power tests.

RESULTS: We found longer time spent during the QF compared to the SF (2.6±3.2 seconds $p < 0.01$) and shorter time spent during the SF compared to the F (-6.8±9.5 seconds $p < 0.05$). Peak velocity and peak oxygen uptake (VO2peak) achieved during the incremental test, showed increasing correlations with performance as the sprint competition progressed. Correlation coefficients (r-values) for peak velocity and VO2peak were -0.73 and -0.51, -0.80 and -0.68, -0.82 and -0.73, and -0.86 and -0.77 in the TT, QF, SF and F, respectively (all $p < 0.05$). Gross efficiency demonstrated consistently large correlations with performance across all efforts (average r: -0.58±0.09), while 30-second poling-ergometer sprint power output demonstrated moderate correlations with performance (r: -0.37±0.22).

CONCLUSION: The gradually increasing correlations observed between peak velocity, VO2peak and performance in the subsequent efforts of a simulated sprint cross-country skiing competition indicate that aerobic power is increasingly important as the competition day progresses.

CRITERION VALIDITY OF PERFORMANCE TESTS AND PHYSIOLOGICAL CHARACTERISTICS IN ELITE CROSS-COUNTRY SKIERS

BUCHER, E., WEHRLIN, J.P., MILLET, G.P., STEINER, T.
SWISS FEDERAL INSTITUTE OF SPORT

INTRODUCTION: Performance testing is an integral component of the training process for elite cross-country skiers. The performance determinants should demonstrate high criterion validity and reflect the physiological demands of on-snow competitions. This study investigated the validity of three aerobic-based laboratory performance tests utilized by Swiss national team athletes.

METHODS: Twenty-nine elite cross-country skiers of the Swiss national team (19 men and 10 women, age: 24 ± 5 and 22 ± 3 years, VO2max: 72.2 ± 2.2 and 60.8 ± 3.8 ml/kg/min, respectively) performed an incremental test to task failure in the classic diagonal technique to measure maximal oxygen uptake (VO2max), a graded exercise test skating (GXT) to assess the second lactate threshold (LT2), and a 24-min double poling time-trial (24-min DP) all on a motorized treadmill using roller skis. Fat-free mass (FFM) was assessed using Dual-energy X-ray absorptiometry. Pearson's product-moment correlations were calculated to assess the relationships between laboratory performance determinants and on-snow sprint and distance performance as measured by FIS points (5th FIS points list 2022/23), with lower points indicating better performance. Correlation coefficients were categorized according to Hopkins (2002).

RESULTS: Large and extremely large associations were found between 24-min DP performance and distance performance in men ($r = -0.55$, $p = 0.022$) and women ($r = -0.91$, $p < 0.001$), respectively. Moderate and very large correlations were observed between absolute VO2max and sprint performance in men ($r = -0.49$, $p = 0.023$) and women ($r = -0.85$, $p = 0.003$), respectively. Relative VO2max and distance performance showed a small correlation in men ($r = -0.28$, $p = 0.111$) and a large correlation in women ($r = -0.66$, $p = 0.268$). LT2 and distance performance demonstrated large to very large correlations in both sexes (men: $r = -0.55$, $p = 0.023$; women: $r = -0.74$, $p = 0.038$). FFM and sprint performance showed a moderate correlation for men ($r = -0.49$, $p = 0.021$) and a very large correlation for women ($r = -0.84$, $p = 0.008$). At the same time, FFM and distance skiing demonstrated a moderate, positive correlation in men ($r = 0.48$, $p = 0.030$) and a moderate, negative correlation in women ($r = -0.41$, $p = 0.403$).

CONCLUSION: Laboratory-derived performance determinants and physiological characteristics such as 24-min DP, VO2max, LT2, and FFM were associated with on-snow distance and sprint performance in male and female elite cross-country skiers, with generally larger correlations in women than men and stronger relationships with distance compared to sprint race performance. Furthermore, the scaling of VO2max (absolute vs. relative) influences the predictive value for on-snow sprint and distance performance and could be utilized to distinguish typical sprint and distance skiers. Our results support the use of the current testing procedures for elite skiers.

PERFORMANCE, PHYSIOLOGICAL, AND PERCEPTUAL RESPONSES OF A FULL SPRINT CROSS-COUNTRY SKIING COMPETITION

TALSNES, R.K., BERDAL, T., BRATTEBØ, J.M., KOCBACH, J., SEEBERG, T., LOSNEGARD, T., SANDBAKK, Ø.
NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY

INTRODUCTION: Sprint cross-country skiing involves ~3 min efforts in undulating terrain, starting with a qualifying time-trial (TT) followed by three subsequent knock-out heats (quarterfinals [QF], semifinals [SF], and final [F]) separated by ~15-90 min recovery periods. However, the actual physiological responses during a full sprint competition, including warm-up, recovery between heats, and cool-down has not yet been investigated. Therefore, this study investigated performance, physiological, and perceptual responses of a full sprint cross-country skiing competition.

METHODS: Eighteen national-level male junior skiers performed a simulated sprint competition in the skating technique consisting of an individual TT followed by 3 heats (QF, SF, and F). A promotion-relegation system was used instead of the regular elimination system so that each skier completed all heats. The skiers were monitored by heart rate (HR) and global navigation satellite system (GNSS) sensors. Perceived readiness (RED, 1-10), rating of perceived exertion (RPE, 6-20), and blood lactate concentrations [La-] were taken at different time points during the competition.

RESULTS: The total time and distance covered during the full sprint competition were 03:30±00:06 h and 25.2±2.9 km, respectively. The skiers spent 02:19±00:27 h between 60-85% of maximal HR (HRmax) and 00:16 ± 00:04 h above 85% of HRmax. Average speed in SF was higher than TT, QF, and F (2.2±2.6%, 1.5±1.8%, 3.9±5.3%, respectively, all $P<0.05$). Average HR was reduced from TT to F (90.5±2.2% vs. 88.0±1.8% of HRmax, $P<0.01$) while [La-] was higher after F compared to TT, QF and SF (10.9±1.4 vs. 9.8±1.6, 9.1±19, and 8.8±1.8 mmol·L-1, respectively, all $P<0.05$). [La-] before F was also higher compared to TT, QF and SG (4.5±2.1 vs. 2.9±1.3, 2.7±1.4, and 2.2±0.6 mmol·L-1, respectively, all $P<0.01$). RED was lower before F compared to TT, QF and SF (6.7±1.3 vs. 8.0±1.0, 7.6±1.2, and 7.4±1.4, respectively, all $P<0.05$) while RPE was highest after TT compared to QF, SF, and F (17.7±0.9 vs. 15.5±1.1, 16.6±1.2, and 16.8±1.8, respectively, all $P<0.01$).

CONCLUSION: This study provides new insight into the physiological demands of a full sprint cross-country skiing competition, emphasizing the need for maintaining high physiological and perceptual effort throughout the competition. The relatively long competition day consisting of repeated efforts of high intensity interspersed with periods of low intensity is unique for sprint cross-country skiing and should be considered while designing corresponding training programs.

COMPARISON OF THE EFFECTS OF HIGH-LOAD VERSUS LOW-LOAD RESISTANCE TRAINING ON SPORT-SPECIFIC PERFORMANCE PARAMETERS IN YOUTH CROSS-COUNTY SKIERS AND BIATHLETES: A PILOT STUDY.

WAGNER, C.M.1,2, SCHMIDT, T.3, WARNEKE, K.1, KEINER, M.2, SCHIEMANN, S.1

<1> LEUPHANA UNIVERSITY, 21335 LÜNEBURG, GERMANY, <2> GERMAN UNIVERSITY OF HEALTH & SPORT, 85737 ISMANING, GERMANY, <3> MEDICAL SCHOOL HAMBURG, 20457 HAMBURG, GERMANY

INTRODUCTION: In sports practice, cross-country ski athletes often incorporate maximum strength- or explosive strength training to their work-out routine. Hypertrophy training, especially in the upper body is generally recommended to be avoided, as increased bodyweight is thought to be detrimental for endurance performance. However, some authors indicated that peak oxygen uptake (VO2peak) is considerably influenced by the active muscle mass during exercise (Larsen et al., 2016). Therefore, it seems reasonable that upper-body hypertrophy could increase VO2peak double poling. The aim of the present pilot study was to compare the effects of two hypertrophy training regimes with high volume on sport-specific performance parameters in elite youth cross-county skiers and biathletes, one with high-load resistance and one with low-load resistance.

METHODS: Fifteen elite youth cross-country skiers (16±2 years, VO2max: 59±7 mL*kg-1*min-1) were assigned either to a high-load resistance training group (HL; n=9) utilizing a 10x 6-12 repetition protocol or a low-load resistance training group (LL; n=6) utilizing 10x 15-20 repetitions. Both groups performed upper body resistance training twice a week for 10 weeks in addition to their regular training routine. The effects on double poling (DP) peak oxygen uptake (VO2peak), on DP power output, on VO2max, and 1-repetition maximum (1RM) for bench pull and bench press were investigated. A two-way ANOVA with repeated measures was performed for data analysis.

RESULTS: T-Test analysis showed significant differences ($p<0.05$) in pretest for maximum strength performances only. ANOVA with repeated measures showed significant increases for nearly all variables (except for VO2max [Eta=0.052, p=0.415]) with a time effect of $p<0.001$, Eta=0.594-0.775 (HL d= 0.42 to 1.02 vs. LL d= 0.05 to 0.73). In both groups the ratio between VO2peak and VO2max was improved (HL: 0.76 to 0.86 and LL: 0.80 to 0.87). However, only for bench press a significant interaction effect [group*time] with larger improvements for HL was calculated ($p=0.044$, Eta = 0.276).

CONCLUSION: Since no significant differences between the HL and the LL group could be observed, the presented results relativize the defensive position regarding hypertrophy training in elite cross-country skiing. In accordance with Larsen et al., 2016, a high-volume strength training routine led to a significant increase in the VO2peak without a significant increase in VO2max, independent on the intensity (HL vs. LL). The presented results indicate a beneficial influence on sport-specific performance parameters in both groups. However, studies with more participants are necessary to be conclusive.

ASSOCIATIONS BETWEEN FORCE-VELOCITY PROFILE, ANAEROBIC CAPACITY AND REPEATED SPRINT ABILITY OF ADOLESCENT ICE HOCKEY PLAYERS.

GLAUDE-ROY, J.

UNIVERSITÉ DU QUÉBEC À TROIS-RIVIÈRES

INTRODUCTION: Anaerobic capacity and repeated sprint ability are key components of performance in ice hockey [1]. Off-season training regularly includes sprint training focusing on the neuromuscular component of theses physiological abilities [2]. Horizontal force-velocity profiling (FVP) has gained popularity as a mean to individualise strength training programs by identifying if an athlete is more "force" or "velocity" oriented [3]. Yet, it remains unclear if a specific profile is favorable to enhanced anaerobic performance. Therefore, this study aimed to explore associations between FVP variables, anaerobic capacities and repeated sprint ability of adolescent ice hockey players.

METHODS: Recruited players were part of the selection process for Hockey Quebec's teams (Male: n = 36, mean age = 15.7 yrs; Female: n=35, mean age = 16.5 yrs). FVP and anaerobic capacity were assessed before the at the early phase of off-season training. FVP was measured during 30-meter sprints. Anaerobic capacity was measured with 2 tests: 1) Wingate test (WAnT30) and 2) repeated sprint test (RAST). Pearson's correlations were computed to explore associations between FVP variables (F0, V0, Pmax, Sfv, Rfmax¬ and Drf), WAnT30 and RAST variables.

RESULTS: F0 had small to moderate associations with anaerobic power indicators (r ranging from 0.28 to 0.49, $p < 0.05$) and moderate associations with anaerobic capacity indicators of both tests (r ranging from 0.31 to 0.36, $p < 0.01$). A small association with the RAST fatigue index ($r = 0.28$, $p = 0.019$). V0 and Pmax had strong associations with anaerobic power indicators (r ranging from 0.50 to 0.78, $p < 0.05$), strong associations with anaerobic capacity indicators (r ranging from 0.54 to 0.81, $p < 0.001$) and no significant associations with fatigue indexes of both tests. Sfv had a moderate association with the RAST fatigue index. Rfmax had moderate to large associations with anaerobic power indicators (r ranging from 0.30 to 0.56, $p < 0.05$), moderate associations with anaerobic capacity indicators of both tests (r ranging from 0.39 to 0.49, $p < 0.001$). Drf had a moderate association with the RAST fatigue index ($r = 0.376$, $p = 0.001$).

CONCLUSION: FVP's strong associations with performance in the RAST (principally V0 and Pmax) suggests that FVP has good predictive validity for the ability to repeat sprints. These associations were weaker with the WAnT30 variables and attributed to natural differences between running and cycling tasks. FVP mechanical components (F0, V0 and Pmax) were

moderately associated with better anaerobic power and capacity in both tests. Mechanical effectiveness (Rfmax¬ and Drf) did not translate to more efficient movement and recovery. An evaluation of athletes' mechanical capabilities through the FVP and anaerobic capacity and resistance to fatigue through the WAnT30 should give a broader view of athlete's physical capacities.

PATIENTS SUFFERING FROM MYOTONIC DYSTROPHY TYPE 1 SEEMS TO TOLERATE RESISTANCE EXERCISE WELL COMPARED TO HEALTHY CONTROLS

HANDEGARD, V., SEYNNES, O., ØRSTAVIK, K., PAULSEN, G., RAASTAD, T.

NORWEGIAN SCHOOL OF SPORT SCIENCES

INTRODUCTION: Patients suffering from most myopathies are recommended to stay active to delay declines in functional capacity and stay ambulatory for as long as possible. Still, a 9-year follow-up study showed that patients suffering from myotonic dystrophy type I (DM1) reduced muscle strength by 25-53% (1). Resistance exercise can be an effective countermeasure against loss of muscle function, but little is known about how intense exercise DM1 patients tolerate. To prescribe optimal dosing of resistance exercise, muscle stress and recovery must be considered. Therefore, the aim of this study was to investigate recovery after moderate-heavy load resistance exercise in DM1 patients compared to healthy controls.

METHODS: DM1 patients (DM1, n=10, 36±12 yrs) and healthy controls (Ctrl, n=10, 27±5 yrs) underwent one bout of unilateral resistance exercise (RE). The exercise consisted of 3 x 6-8 repetitions in leg press and knee extension at 75-85 % of 1 RM. Maximal force-generating capacity (MVC) of the knee extensors was measured prior to and 5 minutes, and 3, 24, 48, and 72 hours after exercise. Blood samples were drawn directly prior to MVCs to measure myoglobin levels. M. vastus lateralis was electrically stimulated with a max twitch contraction before and one hour after exercise. A week before testing, participants were familiarised with testing procedures and scanned using dual X-ray absorptiometry to measure lean leg mass. Analysis of variance using a mixed model was performed to investigate effect of time and disease. Data are expressed as mean ± standard deviation.

RESULTS: At baseline, MVC was significantly lower in the DM1 group compared to the Ctrl group (p=0.04), but there was no difference when strength was normalized to leg lean mass. There was a tendency towards higher myoglobin levels in the DM1 group at baseline (p=0.06). Total load lifted during RE by the DM1 group and the Ctrl group was 1479±730 kg and 2054±893 kg, respectively (p=0.07). The DM1 group experienced an acute decline in MVC of 12±9% five minutes after RE (p=0.01), but at the following timepoints MVC was not significantly different from baseline. The Ctrl group showed no significant decline in MVC following RE. The electrically induced torque was lower in the DM1 group one hour after exercise (p=0.03), while the Ctrl group was unchanged. The myoglobin levels were elevated and peaked 3 h after RE (DM1, 100±69 µg/L; Ctrl, 43±19 µg/L), and the groups differed significantly at 24 h and 72 h after RE.

CONCLUSION: The DM1 group had an acute reduction in both voluntary and electrically evoked force after resistance exercise, but the course of recovery was not different from controls, and the small rise in myoglobin levels excludes severe muscle damage. The present data indicate that well-functioning DM1 patients tolerates moderate-heavy resistance exercise well.

RESTING HEART RATE AND CARDIOVASCULAR MORTALITY IN KOREA: THE MODIFYING EFFECTS OF PHYSICAL ACTIVITY

CHOI, Y.H., KIM, G., YOON, J., HAN, Y., KIM, Y.S.

SEOUL NATIONAL UNIVERSITY

INTRODUCTION: Resting heart rate (RHR) is known as an independent risk factor of cardiovascular diseases (CVDs), and elevated RHR has been associated with various CVDs and related mortality. RHR is determined by numerous factors, including physical activity level. The current World Health Organization (WHO) physical activity guidelines recommend that adults should engage in at least 150 minutes/week of moderate to vigorous physical activity (MVPA). However, it is not clear whether meeting the minimum level of recommended MVPA can modify the association between RHR and CVD mortality. The aim of this study was to examine the combined effect of RHR and MVPA on CVD mortality.

METHODS: This study included 31,698 adults from the 2007-2013 Korea National Health and Nutrition Examination Surveys (KNHANES) who provided data on self-reported physical activity and were linked to the Cause of Death Statistics through December 31, 2019. Multivariate cox proportional hazard models were used to estimate the adjusted hazard ratio (HR) of CVD mortality associated with RHR and MVPA. In combined analysis, participants were classified into 8 categories according to level of RHR (<60bpm, 60-69bpm, 70-79bpm, >=80bpm) and MVPA (<150min/week, >=150min/week). This study used participants in RHR of 60-69bpm with MVPA of >=150min/week as a reference group.

RESULTS: During 9.2 years of follow-up, 311 CVD deaths occurred. Among physically inactive adults compared to the reference group, the adjusted HR (95% CI) for CVD mortality was 2.41 (1.42-4.09) for RHR of <60bpm, 1.59 (1.01-2.50) for RHR of

60-69bpm, 1.98 (1.23-3.20) for RHR of 70-79bpm and 2.41 (1.50-3.89) for RHR of >=80bpm. Among physically active adults, there were no significant associations between RHR and CVD mortality. The results indicate that, regardless of RHR, participants who performed at least 150min/week of MVPA tended to have a lower risk of CVD mortality compared to those who did not meet WHO recommendations.

CONCLUSION: This study suggests that engaging in even the minimum recommended level of physical activity may substantially reduce the risk of RHR-related CVD mortality. The physically inactive group should be the target of preventive health strategies, as supported by this study.

THE EFFECT OF HEALTH PROVIDER'S FEEDBACK ON PHYSICAL ACTIVITY SURVEILLANCE USING WEARABLE DEVICE-SMARTPHONE APPLICATION FOR RESOLUTION OF METABOLIC SYNDROME; A 12-WEEK RANDOMIZED CONTROL STUDY

JANG, M., PARK, J., KIM, D., SUNG, M., SHIN, Y., TAK, Y.

HEALTH CONVERGENCE MEDICINE LABORATORY, BIOMEDICAL RESEARCH INSTITUTE, PUSAN NATIONAL UNIVERSITY HOSPITAL, BUSAN, 49241, SOUTH KOREA

INTRODUCTION: Metabolic syndrome is characterized by the co-existence of several major risk factors for cardiovascular disease, high blood pressure, hyperglycemia, and dyslipidemia (reduced high-density lipoprotein cholesterol [HDL-C] or raised triglycerides). Therefore, appropriate prevention and intervention are required in all related fields. The worldwide increase in recent mobile devices and wearable health work suggests the possibility to overcome the limitations of conventional physical activity healthcare programs. But further research is needed to better understand how or why they work and what factors can mitigate the impact of other groups. This study aimed to evaluate the effect of feedback on clinical indicators in patients with metabolic syndrome on activities measured using wearable devices, such as smartphone apps.

METHODS: In this study we included a total of 67 men and women aged 58.2±10.7 years. Patients with metabolic syndrome were recruited and prescribed to live for 12 weeks using a wrist-wearable device (B.BAND, B Life Inc., Korea). A block randomization method was used to distribute participants between the intervention (n=35) and control groups (n=32). In the intervention group, an experienced study coordinator provided feedback on physical activity to individuals through telephonic counseling every other week. Through the wearable device, it is possible to measure daily physical activity, and it is possible to obtain the values of physical activity time, number of steps, and calorie consumption. Blood pressure, body composition, fasting blood glucose, and lipid profiles were recorded.

RESULTS: The mean number of steps in the control group was 8892.86 (4473.53), and those in the intervention group was 10129.31 (4224.11). After 12 weeks, metabolic syndrome was resolved. Notably, there were statistically significant differences in the metabolic composition among the participants who completed the intervention. The mean number of metabolic disorder components per person remained at 3 in the control group, and decreased from 4 to 3 in the intervention group. Additionally, waist circumference, systolic and diastolic blood pressure, and triglyceride levels were significantly reduced, while HDL-cholesterol levels were significantly increased in the intervention group.

CONCLUSION: Overall, 12 weeks of telephonic counseling intervention using wearable device-based physical activity confirmation improved the damaged metabolic components of patients with metabolic syndrome. Telephonic intervention can help increase physical activity and reduce waist circumference, which is a typical clinical indicator of metabolic syndrome.

EFFECTIVENESS OF PHYSICAL ACTIVITY INTERVENTIONS ON ALLEVIATING PERCEIVED FATIGUE AMONG ADULTS WITH CHRONIC CONDITIONS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMISED CONTROLLED TRIALS

BARAKOU, I., SAKALIDIS, K., ABONIE, U., FINCH, T., HACKETT, K., HETTINGA, F.

NORTHUMBRIA UNIVERSITY

INTRODUCTION: Adults with chronic conditions often experience significant fatigue, which is a barrier to physical activity participation and negatively impacts their health-related quality of life and physical function. Studies have found that physical activity might alleviate perceived fatigue symptoms after exercise in these individuals; however, the findings are conflicting, and no clear recommendations have been given to individuals who experience fatigue. This systematic review and meta-analysis aimed (1) to overview the physical activity interventions of randomised controlled trials (RCTs) aiming to alleviate perceived fatigue symptoms across many chronic conditions using a transdiagnostic approach and (2) to evaluate the effectiveness of physical activity interventions in alleviating perceived fatigue after exercise.

METHODS: Five databases were searched up to November 2021 and two reviewers independently conducted study screening and selection, extracted data, and assessed the risk of bias. The outcome was the standardised mean difference (SMD) with 95% confidence intervals in perceived fatigue between experimental and control groups.

RESULTS: A total of 27 articles met the inclusion criteria. The findings indicated that physical activity interventions alleviated perceived fatigue after exercise symptoms in adults with chronic conditions (SMD=0.61; 95% CI= 0.87 to 0.34; p<0.00001). No effect was found on perceived fatigue of post-trial follow-up. No activity pacing strategies were incorporated into any physical activity interventions.

CONCLUSION: Physical activity interventions were found to have a moderate effect on perceived fatigue reduction among adults with various chronic conditions. Our transdiagnostic approach highlights the important role of physical activity in alleviating the feelings of daily life fatigue in individuals with chronic conditions. We also observed that most physical

activity interventions did not include post-trial follow-up measurements, which are considered essential for identifying potential risks that might not be evident during the trial period as well as to explore sustained effects. After the standardised intervention length, adults with chronic conditions might not be able to keep up with the exercise training program. Activity pacing, which is the process of self-regulation of physical activity levels, has been proposed to be a key factor in fatigue management and exercise engagement. Incorporation of activity pacing into physical activity interventions could result in sustained effects reducing perceived fatigue in daily life and enhancing sustained physical activity engagement.

SPECIFIC EXERCISE IS MEDICINE – PHYSICAL ACTIVITY IS CURRENTLY THE MOST EFFECTIVE TREATMENT OPTION FOR NEUROPATHIES

STRECKMANN, F., BALKE, M., BISCHOFF, C., CAVALETTI, G., TOSCANELLI, A., BLOCH, W., DÉCARD, F.B., LEHMANN, C.H., FAUDE, O.

UNIVERSITY OF BASEL, UNIVERSITY HOSPITAL BASEL

INTRODUCTION: Neuropathies are a prevalent, heterogeneous group of diseases of the peripheral nervous system. Symptoms are often debilitating, difficult to treat, and usually become chronic. Not only do they diminish patients' quality of life, but they can also affect medical therapy and lead to complications. To date, for most conditions there are no evidence-based treatment options available. Specific exercise interventions have proven beneficial to reduce and even prevent a neuropathy. We therefore performed a systematic review with meta-analysis to analyse the potential benefits of exercise interventions for neuropathies of different origin that can then be translated into practice.

METHODS: Two independent reviewers performed a systematic review with meta-analysis according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA). Inclusion criteria according to the PICOS approach were: neuropathic patients, exercise interventions only, an inactive or non-exercising control group, and solely randomized controlled trials with the following outcome parameters: neuropathic symptoms, balance parameters, functional mobility, gait, quality of life, and HbA1c (glycated hemoglobin).

RESULTS: A total of 41 randomized, controlled trials met all inclusion criteria, 20 could be included in the quantitative analysis. Study quality varied from moderate to high. Current data further supports the hypothesis that exercise is beneficial for neuropathic patients. This is best documented for patients with diabetic peripheral neuropathy (DPN) (27 studies) and for chemotherapy-induced peripheral neuropathy (CIPN) (nine studies), while there are only few studies (five) on all other causes of neuropathy. We found standardized mean differences in favor of exercise of 0.27–2.00 for static balance, Berg Balance Scale, Timed-up-and-go-test, nerve conduction velocity of peroneal and sural nerve as well as for HbA1c in patients with DPN, and standardized mean differences of 0.43–0.75 for static balance, quality of life, and neuropathy-induced symptoms in patients with CIPN. Furthermore, we have meanwhile completed a further RCT study that reveals a significant preventive effect of exercise on CIPN by 50-70%: (SMT 30% (95%CI 17·9-42·1%) and WBV 41·2% (27·9-54·5%) vs. TAU 70·6% (58·0-83·2%); pITT<0·0016). This also had a clinical impact, leading to less dose reductions and less mortality in the group that performed sensorimotor training concomitant to therapy.

CONCLUSION: Specific exercise can reduce and even prevent the symptoms of a neuropathy. For DPN, evidence-based recommendations can now be made, suggesting a combination of endurance and sensorimotor training. For CIPN, sensorimotor training remains essential. For all other neuropathies, more high-quality research is needed to derive evidence-based recommendations. Overall, it seems that sensorimotor training has great potential to target most neuropathies and is therefore currently the best treatment option for neuropathies.

MULTIPLE CHRONIC DISEASE CHARACTERISTICS OF THE MIDDLE-AGED SOUTH KOREANS BY A LIFESTYLE USING DATA MINING

HUANG, Y.C., SU, Y.Q., BYUN, Y.H., LEE, Y.G., KIM, S.H.

KOREA UNIVERSITY, DANKOOK UNIVERSITY, UNIVERSITY OF WEST FLORIDA

INTRODUCTION: he term "multiple chronic diseases" (MCD) describes a patient with two or more chronic conditions simultaneously at the same time. Compared with prevalent chronic diseases, it is linked to poorer health outcomes, more difficult clinical management, and higher medical expenses. Several existing MCD guidelines support a healthy lifestyle, including regular physical activities but do not include specific exercise therapy recommendations. This study aimed to understand the prevalence and model of MCD in middle-aged and elderly South Koreans by comparing MCD characteristics with exercise habits to provide a theoretical basis for implementing exercise therapy in these patients.

METHODS: This study was based on data from the "Korean Health Panel Survey" (KHPS). The KHPS is a government-approved statistical survey that has been distributed annually since 2008 to generate national-scale data on healthcare use, medical costs, health levels, and health behaviors. Through rigorous screening of 14 741 participants, 8477 participants, aged > 45 years, with a complete set of exercise-related data and chronic disease data were included in this study. Statistical analyses were performed using IBM SPSS Statistics, version 26.0, and IBM SPSS Modeler, version 18.0. Statistical significance was set at a two-tailed p-value of <0.05. Comparing the MCD characteristics of the participants, the chi-square test for categorical variables and the t-test for continuous variables were used.

RESULTS: In this study, the morbidity rate of MCD was 39.1%. Those with MCD were more likely to be female (p<0.000), seniors over 65 years of age (p<0.000), those with low education level, more than eight h of daily sedentary time (p<0.000), no regular exercise behavior (p=0.001), no sports-related expenses (p<0.000), and no weight management behaviors (p<0.000). Chronic renal failure (93.9%), depression (90.4%), and cerebrovascular disease (89.6%) were the top

three diseases identified in patients with MCD. A total of 37 association rules were identified for the individuals who did not exercise regularly. This equated to 61% more than the regular exercise group, which showed only 23 association rules. In the extra association rules, cardiovascular diseases (150%), spondylosis (143%), and diabetes (125%) are the three chronic diseases with the highest frequency increase.

CONCLUSION: Association rule analysis effectively studies the relationship between various chronic diseases in patients with MCD. It also effectively helps identify chronic illnesses more sensitive to regular exercise behaviors. The findings from this study may be used to formulate more appropriate and scientific exercise therapy for patients with MCD.

INSPIRATORY MUSCLE TRAINING IN THE TRAINING PROCESS OF DISABLED SWIMMERS.

OKRZYMOWSKA, P., SEIDEL, W., ROZEK-PIECHURA, K.
WROCLAW UNIVERSITY OF HEALTH AND SPORT SCIENCE

INTRODUCTION: The purpose of this study was to evaluate the effects of inspiratory muscle training attached to standard swimming training on lung ventilation, inspiratory muscle strength and aerobic endurance levels, as well as the training status of athletes with disabilities participating in swimming.

METHODS: The study was performed in 16 athletes of the Polish Disabled Sports Association "Start". The subjects were divided into 2 groups, allocation to groups was randomized according to the distribution table: group I (IMT group) - athletes performing standard swimming training with attached inspiratory muscle training of medium intensity at a load level of 50% MIP; group II (sham-IMT group) - athletes performing standard swimming training with attached inspiratory muscle training of low intensity at a load level of 15% MIP. All subjects received eight weeks of inspiratory muscle training on personal PowerBreath KH1 devices. The following tests were performed on each athlete: spirometrics, maximum inspiratory pressure (MIP), expiratory pressure (MEP), T-30 test; step test - progressive test 8 x 100. All tests were performed 3 times: I - before the start of IMT, II - after of IMT, III - follow – up after 8 weeks. The results of the study were statistically analyzed using STATISTICA PL V.12.0.

RESULTS: Significant increases in FVC, FEV1, as well as MIP and MEP values were obtained only in group I after applied inspiratory muscle training. In this group, maintenance of the results was observed at follow-up. Also in group I, there was a significant increase in the distance swum during the T-30 test after IMT and a significant maintenance of the effect at follow-up. A significant reduction in lactic acid concentration was also observed in this group and a significant reduction in heart rate at 88% and 93% of maximum speed.

CONCLUSION: 1. Inspiratory muscle training with 50% MIP load significantly increased pyrometric parameters and respiratory muscle strength in disabled swimmers. The disabled swimmers showed maintenance of training effects over a longer period of time at a high level.

2. There were positive distal effects of using training with 50% MIP load in maintaining the achieved levels of respiratory functional parameters.

3. Training of inspiratory muscles at a higher intensity significantly improved the training level of the tested athletes, which was associated with an increase in swimming distance. The use of medium-intensity inspiratory muscle training significantly reduced lactic acid levels in the progressive test. Higher intensity training significantly lowered the heart rate in the 8x100 progressive test at 88% and 93% of maximum speed improving the athletes aerobic endurance.

4. The use of medium-intensity inspiratory muscle training effectively improved the training level and physiological parameters of the swimmers effort. This indicates the need to include this type of training in the standard of competitive preparation of athletes with disabilities.

MOTOR AND MUSCLE ACTIVATION RESPONSES DURING STANDING WITH SENSORY RESTRICTIONS IN CHILDREN WITH CEREBRAL PALSY

PAPAVASILEIOU, A., SAHINIS, C., FABRE, M., THEODOSIADOU, A., BAUDRY, S., LAPOLE, T., AMIRIDIS, I., PATIKAS, D.A.
ARISTOTLE UNIVERSITY OF THESSALONIKI

INTRODUCTION: Cerebral palsy (CP) is a brain disorder resulting in motor disability due to impaired muscle coordination [1], which often leads to increased imbalance and risk of falls. Integration of visual, proprioceptive, and vestibular inputs with motor output is crucial for controlling upright standing [2]. Studying posture by excluding or limiting sensory information helps to understand the dependency of an individual on restricted sensory sources. Knowing that children with CP have a deficit in processing sensory information [3], restriction of sensory sources may further deteriorate their balance control. Therefore, the purpose of this study was to examine the influence of visual and proprioceptive restrictions on balance and muscle activation during upright standing, in children with CP compared with typically developed (TD) children.

METHODS: Ten children with CP (13.0±1.7 yrs, 147.3±0.5 cm, 48.1±0.9 kg) and 16 TD children (14.0±3.8 yrs, 161.2±1.2 cm, 54.8±0.9 kg) were asked to stand on a force platform, in four conditions, with eyes open (EO) or eyes closed (EC), on a rigid (R) or foam (F) surface. The standard deviation (SD) of the center of pressure (CoP) on the anterior-posterior (AP) and mediolateral (ML) direction, the SD of trunk acceleration (TrA), as well as the electromyogram of the soleus (Sol), gastrocnemius medialis (MGas) and tibialis anterior (TA) muscles, were recorded in three 60-s trials in each balance condition. The rate of change for ECR, EOF, and ECF was expressed as the log2 ratio relative to EOR. A linear mixed model was used to compare the differences between conditions, groups, and interactions.

RESULTS: According to the CoP and TrA data, children with CP were less stable than TD children in all 4 conditions. Regarding the relative changes, CoP-AP, CoP-ML, and TrA increased significantly in EOF and ECF compared to EOR, but this increase was less evident in children with CP (interaction p=0.002, p=0.006, and p=0.002). The activation of Sol and MGas significantly increased to a similar extent in both groups at ECR, EOF, and ECF relative to EOR (p<0.05). TA did not demonstrate any significant change (p>0.05).

CONCLUSION: The sensory restrictions applied in children with CP induced a lesser deterioration of their balance compared to TD children. This could be attributed to their greater instability in EOR, compared to TD children. However, the muscle activity changed similarly between the two groups, suggesting a preserved ability of the children with CP to adjust motor command depending on sensory conditions. This could open new directions for training and rehabilitation.

EEG DELTA AND THETA OSCILLATIONS ON PROPRIOCEPTIVE-MOTOR DYSFUNCTIONS IN YOUNG ADULTS WITH A PROBABLE DEVELOPMENTAL COORDINATION DISORDER

CHEN, Y.W.1, LIN, Y.H.1, CHIU, T.F.3, CHUANG, C.H.1,2, TSENG, Y.T.1,2

1 NATIONAL TSING HUA UNIVERSITY. 2 RESEARCH CENTER FOR EDUCATION AND MIND SCIENCES, NATIONAL TSING HUA UNIVERSITY. 3 DEPARTMENT OF COMPUTER SCIENCE AND ENGINEERING, NATIONAL TAIWAN OCEAN UNIVERSITY

INTRODUCTION: Individuals with a probable developmental coordination disorder (pDCD) are known to exhibit proprioceptive dysfunctions that result in abnormal motor execution. To date, no neural mechanism has been identified that underlies brain processes related to proprioceptive-motor dysfunctions in these individuals. This study aims to investigate, via the use of limb proprioceptive motion detection task and time-frequency analysis of EEG, if the neural oscillations in responding to passive limb motion might reveal differences between young adults with pDCD and controls, and to what extent the EEG data is linked to motor performances in young adults with and without pDCD.

METHODS: Thirty-four adults aged between 18-23 years were recruited and categorized into either pDCD group (M ± SD: 21.20 ± 1.17) and control group (M ± SD: 21.30 ± 1.10) based on the results of Bruininks-Oseretsky Test of Motor Proficiency 2nd edition long-form (BOT-2-LF). Participants placed their dominant foot on the paddle of the ankle apparatus that passively moved the ankle at constant velocities of 22°-1 while the EEG was simultaneously recorded. Participants were required to 1) attend to the passive movement and press the button held by the dominant hand once they sensed the ankles motion as fast as possible (voluntary response, VR), or 2) receive purely passive movement (without voluntary response, NVR). The reaction time to passive motion (RT), standard deviation across all reaction time (RT-SD), and EEG power of delta/theta oscillations were obtained in all participants.

RESULTS: In comparison to the control group, young adults with pDCD performed longer RT ($p < .001$) and larger RT-SD ($p = .004$) during the VR condition. Mixed model Analysis of variance (ANOVA) on EEG measures showed a significant interaction effect of Group x Condition ($p = .007$) for delta power. The subsequent post hoc analyses indicated that the VR condition showed higher delta ($p < .001$) and theta ($p < .001$) activities in both groups. Notably, the pDCD group revealed stronger delta power than the DCD group in the VR ($p < .001$), but not the NVR condition. Further correlation analysis indicated that delta oscillation over fontal and premotor cortices was significantly correlated with the RT ($r = -.454$, $p = .001$), RT-SD ($r = -.472$, $p = .005$), body coordination ($r = -.425$, $p = .012$) and strength and agility ($r = -.439$, $p = .009$) of BOT-2-LF.

CONCLUSION: This study demonstrated for the first time that delta power in response to lower limb proprioceptive stimuli is reduced in young adults with pDCD. Such reductions in delta power are significantly correlated with poorer behavioral performance on proprioceptive-motor tasks and lower scores on standardized clinical motor measures. These findings offer the first EEG evidence of proprioceptive-motor function and suggest that delta power might serve as an electrophysiological marker for motor deficits in young adults with pDCD.

KINEMATIC ANALYSIS OF ROWING IN A CHILD WITH CEREBRAL PALSY: A PRELIMINARY STUDY

CAMUNCOLI, F.1, ESTE, A.1, POLISCIANO, R.1, SIMONI, G.1, PICCININI, L.2, GALLI, M.1

<1>. POLITECNICO DI MILANO, <2>.IRCCS EUGENIO MEDEA ASSOCIAZIONE LA NOSTRA FAMIGLIA

INTRODUCTION: Hemiplegia is a pathological condition that affects one side of the body and it is associated with disorders of the upper and lower limbs caused by muscle spasticity. Such disorders are usually remedied by rehabilitative treatments aimed to improving function and aesthetics by correcting rigid deformities [1]. However, therapy alone is not enough to achieve the desired effects. Recent studies have found that increasing patient motivation and focusing on daily activities and participation are the most effective ways to help children with unilateral cerebral palsy recover their function [2].

The aim of the study is to use biomechanical kinematic assessment to determine the rehabilitation impact of rowing on children with unilateral cerebral palsy.

METHODS: The study was approved by IRCCS Eugenio Medea ethics committee and focused on a case study of one child with left hemiplegia. Data was collected using Xsens Awinda and an indoor rowing ergometer connected with ErgData app and with a heart rate monitor. After an initial familiarization, the child was asked to perform the following protocol: 15-stroke trial using (i) only arms and shoulders (AS), (ii) upper limbs and trunk (TA); (iii) legs, arms and shoulders (LTA) and "the

fish game". The whole body kinematic in the sagittal plane, the heart rate during the protocol, the number of stroke per minute, the power the time duration were obtained and processed in an ad hoc Matlab script. The statistical analysis was performed through statistical parametrical mapping [3]. The data normality was verified and a two-tailed paired t-test (α = 0.05) was used to compare the right and left side kinematics.

RESULTS: The child performed the protocol without any interruption. In the LTA, we found statistical differences between the two sides in all joints. The shoulder flexion-extension differed from 63-99% of the stroke cycle, the elbow from the 30-78% of the stroke cycle, the wrist throughout the stroke cycle. As for the lower body, however, the hip did not differ, instead the knee from 0-16%, 85-99% stroke cycle and finally the ankle of the affected side differed from the less affected side from 0-20% and from 73-99% of the stoke cycle.

CONCLUSION: The most significant findings relate to the presence of asymmetry in the sagittal plane of both the shoulders, elbows, wrists, knees and ankles joints at different stages of the rowing cycle. This speculation may be a helpful aid for the clinician to understand whether rowing can be used as a rehabilitation tool in children with unilateral cerebral palsy.

CP-BM03 Motor Learning and Motor Control

CHANGES IN THE MECHANISMS OF CONTROL OF POSTURE DEPENDING ON TASK DIFFICULTY: EFFECT OF DIFFERENT PROPRIOCEPTIVE STIMULATION

FABRE, M.

UNIVERSITÉ JEAN MONNET SAINT-ETIENNE

INTRODUCTION: Proprioception allows us to know at any moment the position of our body and guides our movements. During these movements, the sensorimotor integration allows the link between the sensory integration (like proprioceptive information) and the motor command in the central nervous system (CNS). Proprioception can malfunction, leading to an alteration in balance and walking. To prevent such alteration, it is possible to specifically solicit proprioceptive receptors via local vibration (LV) applied to the postural muscles while performing balance exercises. While this presents promising clinical perspectives, LV perturbates postural control, and could make postural exercises more difficult. Conversely, transcutaneous electrical nerve stimulation (TENS) can also solicit proprioceptive receptors and may favor postural control during postural exercises so that combining LV and TENS may be further relevant for their synergic effects. We therefore investigated how stimulating the proprioceptive system by LV, TENS or their combination may affect balance during postural tasks of increasing difficulty.

METHODS: We calculated the center of pressure velocity (CoP) in both axis of 14 healthy participants for three postural tasks of increasing difficulty: 2-feet eyes closed (1), 1-foot eyes opened (2) and 1-foot eyes closed (3). Each task was performed three times for 20sec in four randomized conditions: no stimulation, LV, TENS and LV+TENS. Two sessions were performed by each participant, with stimulation targeting either the triceps surae or the tibialis anterior muscle.

RESULTS: For LV and LV+TENS there was an increase in CoP speed in both axes compared to no stimulation in task 1, while no differences were observed for tasks 2 and 3. TENS caused no differences in CoP speed for all tasks.

CONCLUSION: This show that proprioceptive stimulation through LV may perturbate balance during easy postural exercises but not when task difficulty increases. This task difficulty-dependent results suggest that the CNS is saturated during difficult tasks by proprioceptive afferences due to mechanical constraints and the increase of proprioceptive afferences this already generates. Moreover, we showed a greater increase of CoP speed in the ML axis compare to the AP for LV and LV+TENS conditions, only for task 1 suggesting that to compensate proprioceptive afferences perturbation the CNS increases the ML oscillations to stabilize and/or gather sensory information. This could imply that proprioceptive afferences from LV is integrated by the CNS as a perturbation in task 1. In task 2 there is a decrease of ML CoP speed compare to AP for LV and LV+TENS, a more classical behavior of standing with no perturbation which could suggest that LV is no more integrated as a perturbation. For task 3 no more difference between both axes probably because participants already are in their limit of stability.

MAGNETIC RESONANCE IMAGING COMPATIBLE ROBOTIC DEVICE FOR EXPLORING THE SUPRASPINAL CONTROL OF GAIT: A SYSTEMATIC REVIEW

HONG, Y.1, ZHOU, J.2, BAO, D.3

1:BEIJING SPORT UNIVERSITY;2:HARVARD MEDICAL SCHOOL;3:BEIJING SPORT UNIVERSITY

INTRODUCTION: The locomotor control of gait is essential for daily activities and athletic performance, which depends upon both peripheral musculoskeletal and supraspinal elements (e.g., brain cortical network). Therefore, the explicit characterization of supraspinal elements can provide critical knowledge to optimize rehabilitative strategies for people suffering from athletic injuries, as well as neurodegenerative diseases.

Magnetic resonance imaging (MRI) is one widely-used neuroimaging technique that can provide sophisticated measurements of the structure and functions of supraspinal neural regions. However, people are required to stay motionless during MRI scan, largely limiting the feasibility of studying the supraspinal networks pertaining to gait. To overcome this, researchers have developed MRI-compatible devices to apply the stimulation mimicking the locomotor control of gait without interfering with the imaging quality. However, large variance in the design and functionalities of these devices existed, leading to uncertainty of the interpretation of the observations, and implementation of these devices.

OBJECTIVES: We here performed a thorough systematic review to review and summarize the research and development progress of these devices.

METHODS: Seven electronic databases PubMed, Web of science, EBSCO MEDLINE, SPORT Discus, Psych-Info, Cocaine Library and Scopus were searched (until 27 August 2022). The information related to device structures and functionalities, study protocols, and observations from MRI, was extracted.

RESULTS: Twenty-six studies were included, including 13 types of devices from 12 groups and 371 participants across nine countries. Three devices applied only somatosensory stimuli to foot soles, eight only motion stimulation to lower-extremities, and two both types of stimulation. The MRI compatibility (n=7) and the validity of device performance (e.g., head motion) (n=9) were reported. It was observed that the primary and secondary sensorimotor cortex, prefrontal cortex, and the cerebellum were activated in response to gait-related stimulations.

CONCLUSION: All these devices were successfully implemented during MRI scan and reliable data were obtained, suggesting it is feasible to implement these devices to characterize supraspinal networks pertaining to locomotor control of gait in different populations. However, inconsistent observations were presented, potentially stemming from varied designs of devices or study protocols (e.g., relatively small sample sizes). The following aspects are thus needed to be carefully considered and focused on: (1) to improve the quality of gait simulation using for example, independently-controlled pneumatic actuators to smooth the force control over with individualized shaped surface; (2) to simultaneously measure the muscular characteristics during the stimulation using electromyography, enabling the characterization of the supraspinal and peripheral coupling related to locomotor control.

MOTOR-COGNITIVE STRATEGIES TO INFLUENCE THE NEURAL CONTROL OF BALANCE: AN FNIRS STUDY.

GEMMERICH, R.1, KIEFFER, S.2, ZIEGLER, T.2, SCHEPPMANN, J.1, LAUSBERG, H.2, HELMICH, I.1,2

GERMAN SPORTS UNIVERSITY COLOGNE, GERMANY

INTRODUCTION: With age, postural control deteriorates because of changes in the sensory and motor systems (da Silva Borges et al., 2021). Results of behavioral and neuroimaging studies have also shown that not only subcortical structures such as the brainstem, cerebellum, and spinal cord (Sherrington, 1910; Takakusaki, 2017) but also sensorimotor areas influence postural control (Mihara et al., 2008; Lin et al., 2017). Furthermore, there is a scientific consensus on the functional reciprocal link between language processing and motor actions. For instance, reading or listening to words that refer to bodily actions elicits activity in brain motor areas involved in action production (see Pulvermüller & Fadiga, 2010 for a review). Because increases in measured cortical activity compensate for sensorimotor deficits and thus maintain postural stability (St George et al., 2021), we hypothesized that motor-cognitive processes exhibit reduced body sway with concomitant increased brain oxygenation. Here, functional near-infrared spectroscopy (fNIRS) allows us to analyze brain oxygenation during both cognitive tasks and postural control (Helmich et al. 2015, 2016, 2020).

METHODS: The sample includes 43 active and healthy (no neurological or orthopedic diseases) athletes (39 men; 31 right-handed, 12 left-handed) mean age: 21.8 ± 4.11 years). Postural control was assessed using a pressure distribution measurement system (type FDM XS from zebris Medical GmbH) during (I) eyes open/closed; (II) standing on a stable/unstable surface; and (III) with/without cognitive priming task. Tasks were divided into a motor-cognitive (taskmotor: reciting motor actions) and non-motor-cognitive (tasknon-motor: reciting numbers) task. Neuronal activation of postural control was derived using mobile fNIRS (NIRSSport2, NIRx GmbH, 8 sources, 8 receivers, 18 channels) over sensorimotor areas of the left and right hemispheres.

RESULTS: The results of postural control of taskmotor on an unstable standing surface and with eyes closed show a significant reduction of body sway [smaller area of the confidence ellipse in mm²] compared to postural control without a task. Results with fNIRS show a significant increase in brain oxygenation [ΔHbO] in a left hemisphere channel localized in the premotor cortex during taskmotor compared to measurement without a task.

CONCLUSION: Results show reduced postural sway using motor-cognitive acquisition during postural control with eyes closed and unstable standing surface. The associated increase in brain oxygenation shows that motor action can be initiated by motor-cognitive tasks, thereby improving postural control. These findings can be used to optimize rehabilita-

tion interventions for diseases with balance impairments and to improve the understanding of postural control mechanisms, which has important implications for exercise science and rehabilitation.

ACTIVATION OF ABDOMINAL MUSCLES DURING FORCED EXPIRATION AT VARIOUS EXPIRATORY MOUTH PRESSURE LEVELS

CHINO, K., OHYA, T.

KOKUGAKUIN UNIVERSITY, SPORTS OKINAWA, CHUKYO UNIVERSITY

INTRODUCTION: During forced expiration, active muscle contraction of the rectus abdominis (RA) and the oblique externus abdominis (OE) is required to reduce intrathoracic volume rapidly. Considering the origin and insertion of the RA and OE, it is clear that active contraction of these muscles contributes to forced expiration. However, if these muscles are not actively contracting during forced expiration, they will not be able to contribute to forced expiration. Therefore, this study measured the activation of the RA and OE during forced expiration at various expiratory mouth pressure levels by surface electromyography (EMG).

METHODS: Twelve healthy male participants performed forced expiration at 30%, 50%, 75%, and 100% of the maximal expiratory mouth pressure (PEmax). During forced expiration, the EMG activity of the upper RA, the lower RA, and the OE was measured by surface EMG. The root mean square (RMS) amplitude of the EMG activity during the forced expiration was calculated and normalized to the RMS amplitude during the maximal voluntary contraction (MVC) in an isomeric abdominal crunch (for the upper and lower RA) or twist crunch (for the OE).

RESULTS: The PEmax was 128 ± 9 cmH2O, corresponding to 107.2 ± 21.5% of the PEmax predicted by sex, age, height, and weight. The EMG activity during forced expiration was clearly lower than that during MVC in isomeric abdominal (twist) crunch and greatly varied with participants: the EMG activity during forced expiration at 100% of the PEmax was 16.0 ± 18.4% of the MVC (Coefficient of Variation: CV = 115.3%) for the upper RA, 14.2 ± 12.6% of the MVC (CV = 88.6%) for the lower RA, and 28.2 ± 14.2% of the MVC (CV = 50.2%) for the OE. The EMG activity during forced expiration tended to increase with increasing expiratory mouth pressure levels. A two-way analysis of variance revealed a significant interaction between muscle and mouth pressure levels. Post hoc multiple comparisons revealed that the EMG activity of the upper RA was significantly different among the mouth pressure levels except for between 30% and 50% of the PEmax and between 75% and 100% of the PEmax. In the EMG activity of the lower RA, significant differences were found only between 30% and 100% of the PEmax and between 50% and 100% of the PEmax. In the EMG activity of the OE, significant differences were found among the mouth pressure levels except for between 30% and 50% of the PEmax. The EMG activity at 100% of the PEmax was significantly higher in the EO than in the lower RA.

CONCLUSION: The finding that the EMG activity of the RA and EO was clearly lower during forced expiration than during abdominal (twist) crunch and the EMG activity during forced expiration greatly varied with participants shows the difficulty of using abdominal muscles for forced expiration.

MOTOR IMAGERY SPEEDS IN THE FOOTBALL DRIBBLING TASK: AN EEG STUDY

ZAMANI SANI, S.H.1, FATHIREZAIE, Z.1, BRAND, S.2, MOHAMMADZADEH, S.3, ABBASPOUR, K.1, SADEGHI-BAHMANI, D.4, REZVANI, Z.5

1. UNIVERSITY OF TABRIZ., 2. UNIVERSITY OF BASEL., 3. DAMGHAN UNIVERSITY., 4. STANFORD UNIVERSITY., 5. INSTITUTE FOR RESEARCH IN FUNDAMENTAL SCIENCES.

INTRODUCTION: Motor imagery (MI) is a mental process to rehearse or simulate a given action (Guillot & Collet, 2008). MI is also described as explicit and implicit mental representation of an action with or without concomitant movements (Ruffino, Papaxanthis, & Lebon, 2017). The following factors should be considered when performing MI: Timing (Holmes & Collins, 2001), and temporal characteristics or temporal equivalence (Guillot & Collet, 2008). However, Louise et al. (Louis, Guillot, Maton, Doyon, & Collet, 2008) and Boschker et al (Boschker, Bakker, & Rietberg, 2000) showed that voluntarily increasing or decreasing the movement speed during MI impacted the actual movement speed. With this in mind, two types of imagery were examined in this study, slow-motion imagery and fast-motion imagery. Therefore, in order to know about the neurological basis of different modes of MI, we decided to examine the activity of alpha and beta waves at the brain cortex regions in these two types of imagery.

METHODS: To this end, participants were asked to imagine a football dribbling task at rest state, slow and fast speeds, while their neuronal activities were registered via brain electroencephalography (EEG). 10 healthy adolescent athletes took part in the study. Participants' neuronal oscillations were recorded using an international 10–20 electro-encephalogram (EEG)-system to assess alpha (8 Hz – 12 Hz) and beta (18 Hz – 28 Hz) frequency bands.

RESULTS: Alpha wave activity was higher at frontal, temporal, and occipital regions; beta wave activity was higher at frontal and temporal regions. Compared to the default mode resting state, during the fast motor imagery, alpha wave activity was higher at Fp2, F3, F8, C3, P3, and O2; and beta wave activity was higher at O1 and O2. During the slow imagery, only beta wave activity was higher at P3 and Pz. Slow imagery further activated the left areas of the brain (frontal, temporal, and parietal), while fast imagery further activated the fronto-central and posterior sections. In addition, alpha/beta ratios showed higher activity in the rest state than in slow (Pz) and fast (O1) states.

CONCLUSION: The present study adds to the current literature in the following ways: generally, more activation of brain regions was found in the fast-motion imagery than in slow-motion imagery. Slow imagery was associated with increased beta activity; while, fast-speed imagery was associated with increased alpha activity compared to the rest state. As well,

the representation of EEG activity during slow-motion imagery was consistent with previous findings about more attention during motor learning. In addition, the activity of the alpha band was very widespread in fast-motion imagery at the prefrontal, frontal, central, parietal, and also occipital regions of both sides of the cortex. In contrast, beta-band activity was more in the posterior regions of the brain.

INTERPERSONAL SYNCHRONIZATION BETWEEN SPRINTERS: AN OBSERVATIONAL STUDY OF THE JAPANESE 100-M RECORD RACE

FURUKAWA, H., MIYATA, K., RICHARDSON, M., VARLET, M., KUDO, K.

THE UNIVERSITY OF TOKYO

INTRODUCTION: Athletes' performances are determined not only by individual ability but also by environmental states, especially the behavior of competitors. Previous studies suggest that spontaneous interpersonal synchronization occurs when individuals can see and hear each other's action. One study reported interpersonal synchronization between Usain Bolt and Tyson Gay in the 100-m race in which Bolt broke the world record and Gay broke the U.S. record (Varlet & Richardson, 2015). This report suggests that interpersonal synchronization may, in some cases, enhance an athlete's performance. In this study, we report a new case of the potential positive effect of interpersonal synchronization on athletes' performances.

METHODS: In the men's 100-m final at the Fuse Sprint (Tottori, 2021) in Japan, the first-place sprinter broke the Japanese 100-m record, and the second-place sprinter set his new personal record. These two sprinters ran side-by-side throughout the race. We analyzed the video of this race using deep learning-based estimation of human joint coordinates (OpenPose) (Cao et al., 2021). First, we obtained time series data of ankle joint coordinates for each sprinter. Then, to examine the degree of synchronization between two sprinters, the relative phase between their steps was then calculated using the negative peaks of the time series data. We also analyzed the video data of preliminaries in which the sprinters ran in different races to determine the chance level of synchronization.

RESULTS: Our results showed that the difference in cadence between the two sprinters was smaller and the relative phase between the two sprinters was more synchronized (inphase) in the final race compared to the chance level of synchronization determined by the preliminary races.

CONCLUSION: These changes in cadence or relative phase could not be explained by the difference in running speed between the final and the preliminaries because the time difference between them was the same (0.06 seconds) in the final and the preliminaries. This result supports the hypothesis that spontaneous interpersonal synchronization can occur between the two sprinters running side by side. It is noteworthy that both the world and Japanese 100-m records were set in races in which the first- and second-place sprinters synchronized their running movements. Our study provides additional evidence to suggest that interpersonal synchronization can influence the cadence of sprinters and enhance their performance.

HOLD YOUR FIRE! EFFECTS OF MENTAL FATIGUE ON MOTIVATION, EXECUTIVE FUNCTION, EYE-MOVEMENTS, AND SIMULATED GUN-SHOOTING PERFORMANCE.

SABATTINI, L.1, GALLICCHIO, G.2, MARCORA, S.1, PIRAS, A.1, COOKE, A.2

1 ALMA MATER STUDIORUM UNIVERSITY OF BOLOGNA, BOLOGNA, ITALY; 2 BANGOR UNIVERSITY, BANGOR, UK

INTRODUCTION: Mental fatigue (MF) is a psychobiological state characterised by feelings of tiredness and lack of energy and caused by prolonged and demanding cognitive activity. There is evidence that MF can affect physical performance through impaired cognitive control; however, most studies have focused on endurance and strength in sports. In this study, we used a psychomotor shooting task requiring attentional control and response inhibition and measured behavioural performance and concomitant visual behaviour as an index of visual attention. We also evaluated mental fatigue-induced changes to the capacity to inhibit selective information.

METHODS: Sixteen participants visited the lab on two different days. On the experimental day, they completed a 50-minute computer task requiring selective visuospatial inhibition (Flanker task) to induce mental fatigue. On the control day, they viewed a 50-minute documentary. Before and after the fatiguing protocol (or the documentary), we assessed self-report MF (VAS and Fatigue-Fatigability) and inhibition performance at two computer tasks (Stop-Signal and Simon tasks). After the fatiguing protocol (or the documentary), we measured self-control capacity (State Self Control Capacity Scale), self-report motivation as the willingness to engage in more of the computer tasks or more of the shooting task (bespoke questions), and psychomotor shooting performance as the number of civilians-casualties (on whom firing should have been inhibited) along with the visual behaviour through mobile eye tracking (EyeLink® II).

RESULTS: After the fatiguing protocol, self-control capacity was lower ($p=0.020$), fatigability was higher ($p=0.015$), motivation to engage in more of the computer task was lower ($p=0.029$), and the pre-to-post drop in energy level was more pronounced ($p=0.014$) compared to the control documentary. Despite these self-report differences, shooting performance, fixation, and saccade parameters did not differ between the fatiguing protocol and the documentary ($p>0.05$), nor did the pre-to-post changes in inhibition task performance ($p>0.05$).

CONCLUSION: Despite the participants feeling more fatigued after the fatiguing protocol as expected, their inhibition capability, shooting performance, and visual attention were not impaired compared to the control documentary condition. These null effects might be due to the participants' eagerness to engage in anything else (but especially in such an attractive task as simulated shooting) after performing nearly 1 hour of the same activity (Flanker task or documentary). It may

also be that the documentary induced boredom, and that prolonged engagement with it required participants to exercise self-control, which in turn could have produced mental fatigue. Finally, the participants may have exerted greater effort to compensate any detrimental effect of mental fatigue on cognitive and psychomotor performance. We encourage future research to test these interpretations.

TWO-DIMENSIONAL TRIAL-BY-TRIAL ERROR CORRECTION FOR ACCURACY IN HIGH-SPEED PITCHING TASK

KUSAFUKA, A., OKEGAWA, T., YAMAMOTO, R., MIYATA, K., KUDO, K.

THE UNIVERSITY OF TOKYO

INTRODUCTION: Accurately and repeatedly controlling a ball to a target position in high-speed is one of the human specific motor skills. This can be observed as various sports-related skills, such as pitching, kicking, and batting. The arrival position of the ball can be approximately determined by its physical state at the release or impact. In high-speed baseball pitching, reducing the variability of the ball's release angle is known to be necessary to reduce the variability of arrival position. However, as there is always variability in human movements and it increases as the speed increases, how to decrease the variability is one issue. This study focused on one strategy; trial-by-trial error correction, which is to correct movements in the following trials facing an undesirable outcome. We developed a new method to clarify the error correction in two-dimension and performed on the intertrial changes of the elevation/azimuth release angle in skilled baseball pitchers.

METHODS: Two synchronized high-speed cameras (960 fps) were used to capture the 30 fast balls each for 14 college pitchers aiming a target at 18.44m away. 3D positions of the ball were obtained from the camera images digitized by an automatic image recognition based on deep learning (DeepLabCut). Speed was defined as the magnitude of velocity vector at the ball release. The release angle was given by the elevation and azimuth angle of velocity in polar coordinates. Two-dimensional (elevation/azimuth) release angles were divided into four states according to whether they are larger or smaller in each direction than the average value of each pitcher, and the transition probability from each state to state was calculated. The transition probabilities were summed according to the direction of the transition as the frequency of error correction, and whether each of them was greater or less than the chance level was tested. In addition, the correlation between each of probabilities and the variability of release angle was investigated.

RESULTS: Bootstrap test using surrogate data showed that the transition probability of elevation direction was larger than the chance level with a significant tendency, while that of any other direction was not. In addition, the grater the transition probability to the same state, the grater the variability of azimuth release angle (and the ratio of variability of azimuth release angle to elevation release angle).

CONCLUSION: The skilled baseball pitchers tended to correct elevation error most frequently. In addition, the pitchers who made no error correction frequently had more variability of azimuth release angle (and the ratio of variability of azimuth release angle to elevation release angle). These findings suggest that trial-by-trial error correction can be one strategy to decrease the variability in high-speed motor tasks. Furthermore, the result that it can influence on the shape of the two-dimensional variability indicates the importance of analyzing error correction in two-dimension.

MODULATING AROUSAL VIA PUPIL-BASED NEUROFEEDBACK: A POTENTIAL MENTAL TRAINING APPLICATION IN SPORTS?

WEIJS, M.L., MEISSNER, S., BAECHINGER, M., KIKKERT, S., IMHOF, J., MISSURA, S., CARRO DOMINGUEZ, M., WENDEROTH, N.

ETH ZURICH

INTRODUCTION: A growing body of evidence suggests that intermediate arousal levels are essential for optimal performance. Self-regulation of the brain's arousal state can be particularly challenging in high pressure competition settings. The locus coeruleus (LC) is the principal source of noradrenaline in the brain and is one of the key regulators of the brain's arousal level. Additionally, it modulates autonomic arousal, marked by heart rate variability (HRV) changes, via projections to the brainstem and spinal cord. Interestingly, there is ample evidence for a link between LC activity and non-luminance dependent pupil size changes. Building on this evidence, we investigated whether changes in pupil size (i) can be volitionally induced via pupil-based neurofeedback (pupil-NF) training and are linked to changes in (ii) autonomic nervous system functioning as indexed by HRV.

METHODS: In experiment I, 54 healthy volunteers (19-47 years) received 3 days of pupil-NF training to learn to volitionally up- and downregulate pupil size. 28 control participants (19-40 years) received the same amount of training and instructions on mental strategies but no veridical pupil-NF. To explore the link between pupil size changes and cardiovascular function, 25 pupil-NF participants underwent follow-up sessions combining pupil-NF with pulse oximetry to measure heart rate and HRV. In a replication experiment, 23 participants (21-41 years) completed a slightly adapted pupil-NF training with simultaneous electrocardiography (ECG) recordings.

RESULTS: Participants of the pupil-NF group were able to successfully self-regulate their pupil size (pupil modulation index after the final day of training $M = 0.34 \pm 0.28$). Such self-regulation was significantly reduced in control participants (pupil modulation index $M = 0.09 \pm 0.12$; main effect of group: $F(1,21.58) = 21.49$; $p = .001$). Pulse oximetry and ECG analyses revealed that pupil self-regulation was linked to changes in cardiovascular measures: we found higher heart rate during blocks of volitional pupil size up- than downregulation in the main experiment ($Mup = 76.92 \pm 7.67$; $Mdown = 70.18 \pm 8.03$; $t(23) = 6.644$; $p < .001$) and replication experiment ($Mup = 76.44 \pm 9.82$; $Mdown = 73.28 \pm 9.71$; $t(21) = 3.97$; $p < .001$). In contrast, we observed a trend towards higher HRV during pupil size down- than upregulation in the main exper-

iment (Mdown = 54.58 ± 35.51; Mup = 47.78 ± 28.29; Z = 1.91, p = .056) and a significantly higher HRV during down- than upregulation in the replication experiment (Mdown = 64.91 ± 71.18; Mup = 54.24 ± 63.84; Z = 2.97, p = .003).

CONCLUSION: This proof of concept study provides evidence that pupil-NF makes the brain's arousal system accessible to volitional control. This finding has tremendous potential for translation to pupil-NF-guided mental training applications in the sports domain, by enabling athletes to volitionally control their arousal state in situations of high performance and recovery.

PRELIMINARY FINDINGS OF HIGH-DENSITY EEG SOURCE IMAGING DURING INCREMENTAL CYCLING TASK

OCVIRK, T., ARTONI, F., MICHEL, C., PESKAR, M., RAKUŠA, M., MARUSIC, U.

UNIVERSITY OF GENEVA

INTRODUCTION: Understanding brain dynamics under natural conditions remains a challenge due to the technical limitations of brain imaging techniques. Advanced processing procedures for artifact removal enabled high-density mobile electroencephalography (EEG) to be used in dynamic settings. Previous EEG studies on cycling showed that primary motor cortex activity increases with the duration and intensity of cycling [1,2]. In contrast, when Fontes et al. [3] compared low to high intensity cycling they observed that the activation of the motor cortex remained similar throughout the duration while activation of the prefrontal cortex decreased in both intensities. In addition, the cerebellum was activated at lower intensities. The aim of this study was to replicate the design used by Fontes et al. [3] while using high-density source imaging.

METHODS: 14 subjects aged 19 to 35 years performed incremental exercise on a cycling ergometer. After a 5-minute warm-up cycling all participants started to cycle at 50 watts, which was increased in 25-watt increments. Each intensity block consisted of cycling four times with a 30-second rest. Participants cycled until they reached a score of 17 on a Borg scale of 6-20. Low and high intensities were pooled from 50 to 100 and 125 to 200 watt, respectively. Before, during, and after cycling a 64-channel EEG (Brain Products, GmbH) was used to record electrocortical activity. Data were preprocessed with EEGLAB (Delorme and Makeig, 2004) and imported into Cartool 3.8 (Brunet et al. 2011) to localize sources within the cortex.

RESULTS: All subjects successfully completed cycling tasks with 271 ± 65 W of maximal cycling intensity (Borg scale = 17). Preliminary results show consistent activation of the cerebellum and motor cortex at both low and high intensity of cycling

CONCLUSION: Although EEG seems promising for source localization in such a design, several more subjects may need to be analysed and presented to draw generalizable conclusions. A direct comparison with Fontes et al. [3] revealed that our subjects reached higher maximal intensities and similar brain areas were involved. Finally, discussion about the most optimal EEG cleaning procedures for source imaging will be provided.

CP-AP12 Health and fitness

THE EFFECT OF BODY COMPOSITION ON SHORT AND LONG SPRINTS, AND ENDURANCE RUNNING PERFORMANCE IN MALE AND FEMALE STUDENTS

KACEM EP FTAITI, A.

MEDCINE FACULTY, PHYSIOLOGY AND FONCTIONEL EXLPOLORATION

INTRODUCTION: Intersex differences in performance are the result of lifelong interactions between genetic inheritance and environmental factors (e.g. balanced nutrition, prevention against infectious diseases, level of physical activity...). Thus, during the 20th century, the improvement of living conditions for most humans has led to anthropometric changes (i.e. mainly an increase in height and weight) in both sexes. However, technology and its consequences on the mechanization of our lifestyles (e.g. travel, mechanical handling, etc.) has drastically decreased our level of daily physical activity, which in turn has lowered the physical performance of adolescents and has led to the development of noncommunicable diseases in older adults (cf. "epidemiological transition")

METHODS: 72 male and 64 female students aged 20 to 23 years participated in this study.

After assessing their morphological characteristics (body mass, percentage of fat mass), running performances during 30 m and 400 m, and maximum aerobic velocity (MAV) and maximal oxygen consumption (VO2max) during a 20 m shuttle running test have been estimated for each subject.

Male students were re-tested after being overweighed down with a weight equivalent to the mean differences in body fat recorded between the two sexes in the form of a loaded worn vest.

RESULTS: Male are 15,7% heavier and 7,4% taller (p <0.001) and presented a percentage of fat mass (17.2 ±2%) significantly (p <0.001) lower than that of women subject (25.0 ±2.5%) (difference male vs female for body fat mass: 45.34%).

Running performances during 30 m and 400 m, MAV and VO2max were significantly (p <0.001) better in males (4.81 ± 0.11 sec, 61.97 ± 2.63 sec, 12.53 ± 0.54 km/h and 49.67 ± 3.3 ml/min/kg, respectively) than in females (5.58 ± 0.31 sec, 87.95 ± 8.93 sec, 10.38 ± 0.57 km/h and 37.22 ± 3.31 ml/min/kg, respectively)

In the weighted condition, male performances during 30 m and 400 m, MAV and VO2max were attenuated by 6.89%, 14.16%, 6.48% and 10.07%, respectively) but remain significantly better than those of female students.

Cancelling the intersex difference in body fat mass by overweighting male subjects reduced by to 57.14%, 66.22%, 62.21% and 59.84% the intersex difference for performances during 30 m and 400 m, MAV and VO2max, respectively.

CONCLUSION: Speed performance over 30 and 400 m (i.e. short and long sprints, respectively) and SRT are significantly better in male subjects compared to female one. Relative differences represented -16,1%, -41,92%, -17.15% and -25.08% of the male performances for 30 m, 400 m, MAV and VO2max, respectively.

The persistence of intersex differences after overweighting male subjects indicates that other factors than body fat mass could be responsible for only 9.2%, 27.8%, 10.67% and 15.01% of observed intersex differences for 30 m, 400 m, MAV and VO2max performances, respectively.

BREAKING DOWN THE CROSSFIT GAMES: A 10-YEAR ANALYSIS OF THE COMPETITION AND TOP ATHLETES. ARE THEY THE FITTEST ON EARTH?

STRUNK-POMAR, R., SANTOS-CONCEJERO, J.

UNIVERSITY OF THE BASQUE COUNTRY UPV/EHU

INTRODUCTION: This study aimed find exercise type and distribution patterns within the CrossFit Games, a seemingly random competition, where participants are challenged through a wide range of functional movements that involve lifting large loads and covering long distances as fast as possible with the goal of finding "the fittest man and woman on Earth"®

METHODS: Information was gathered from a publicly accessible website (www.games.crossfit.com/games). Data analysed includes The CrossFit Games workouts from 2011 until 2021. Every WOD was broken down by gender and target, which included rounds for time (RFT), for time (FT), repetition maximum (RM) and as many reps/rounds as possible (AMRAP). Exercises were classified into 3 main groups Metcon, Gymnastics and Weightlifting. Additionally, the Weightlifting category was subdivided as follows: Olympic Weightlifting (OW), Barbell Weightlifting (BW) and Object Weightlifting (OBW).

RESULTS: 150 WODs were analysed, which included 68 different exercises and 94 exercise variations. 57% of the exercises fell into the Weightlifting category, from which 44% corresponded to OBW, 7% to OW and 6% to BW. 26% of the exercises were classified as Gymnastics and the remaining 16% fell into the Metcon category. Each year averaged 13.6 ± 2.4 events per year. Each day of competition averaged 3.3 ± 0.9 WODs, with no differences between competition days (day 1, 2, 3 or 4; p=0.546). Within WOD exercise number averaged 2.5 ± 1.5 exercises per WOD, ranging from 1 to 7 exercises. When rounds were included into the workout, they averaged 4.5 ± 2.2 rounds per event. Among event goals, FT and RFT represented 85% of the total, whereas RM and AMRAPs were 9% and 3%, respectively. We found no differences between the load lifted throughout the years (p=0.530). We found no differences between the exercise classification and day of competition among years (p=0.317), nor between exercise classifications and days of competitions. 79% of the WODS lasted less than 20 min, 16% lasted more than 30 min and barely 5% lasted between 20 and 30 min. On day 1, there seemed to be an even distribution among shorter (<11' and ≥11'-≤20') and longer (<20'-≤ 30' and >30') WODs. On day 4, 90% of the WODs lasted less than 20 min (70% last less than 11 min) and only 3% of them lasted more than 30 min.

CONCLUSION: Despite CrossFit®s self-implemented philosophy of randomness, according to our analysis, athletes at the CrossFit Games can expect a reduction in the number of longer events (>30') and an increase in the number of shorter ones (<11') as competition days pass and expect heavy events on day 3 of competition. Athletes should also expect Metcon type WODs to be the most frequent, being running, muscle-ups, rowing, snatch, and pull-ups the most frequent exercises. This highlights the combination of endurance, strength and skill that athletes need to display in this competition

HEART RATE-BASED ESTIMATES OF METABOLIC INTENSITY OF AEROBIC EXERCISE IN POST-MENOPAUSAL WOMEN: APPLICATION AND PERFORMANCE.

COLOSIO, A., TESO, M., BOONE, J., POGLIAGHI, S.

UNIVERSITY OF GHENT

INTRODUCTION: Regular aerobic exercise maintains fitness and counters the detrimental effects of ageing on health and function, in an intensity-dependent manner. Accurately monitoring exercises metabolic intensity (MET) is crucial to reach these goals. However, its implementation is constrained by expensive equipment and trained staff. Heart rate (HR) is a simple, low-cost alternative for MET estimation but its accurate implementation still requires a preliminary lab test. To overcome this limitation, HR equivalents (absolute HR, HRnet, HRindex) may be used, yet the validity of these indexes of

MET in specific populations is unclear. This investigation aims to verify the existing relationships between HR equivalents and MET and test their performance at different intensities in postmenopausal women.

METHODS: 14 postmenopausal women (59±6 years, menopause: 4±3 years, VO2max 34±9 ml/min/kg-1) performed a cycling ramp incremental test aimed at verifying the relationships between MET and absolute HR, HRnet and HRindex. Then, both general and population-specific equations were tested in a second group of 10 postmenopausal women (54±3 years, menopause: 3±2 years, VO2max 35±5 ml/min/kg-1) who performed six constant work exercises of 10 min between 40% and 90% of the VO2max. Breath-by-breath pulmonary gas exchange and HR were continuously measured using a metabolic cart. General and population-specific equations for post-menopausal women were compared on the agreement between the coefficients. Estimated and measured MET were compared using correlations, Bland-Altman analysis and two-way RM ANOVA.

RESULTS: Strong linear relationships were found between absolute HR (r = 0.90), HR net (r = 0.93), HR index (r = 0.92) and MET. The ones of absolute HR and HRnet were found to differ from the general relationships, while the relationship of HRindex did not differ. When population-specific equations were applied to estimate MET, measured and estimated MET were medium to highly correlated and showed acceptable precision and non-significant biases (absolute HR r=0.74, imp=21.6%, z=0.25; HRnet r=0.88, imp=14.7%, z=0.12; HRindex r=0.89 imp=14.0%, z=-0.48), with better performance displayed by both HRnet and HRindex compared to absolute HR. Statistical differences between measured and estimated MET was found only at 80% VO2max for absolute HR at 90% VO2max for HR. General HR equations displayed similar correlations coefficients with MET than population-specific equations, but also larger biases and imprecision (absolute HR r=0.75, imp=23.3%, z=-0.89; HRnet r=0.89 imp=15.4%, z=-1.50; HRindex r=0.89, imp=14.9%, z=-1.25) and statistical differences were detected at all the trial intensities investigated.

CONCLUSION: Our results support the need for, and provide, population-specific equations to estimate MET in postmenopausal women using HR. HRnet and HRindex show superior performance than absolute HR in estimating MET. Between the general equations of HR, HRindex shows a slightly superior performance.

THE INFLUENCE OF AGE ON PHYSICAL FITNESS, OCCUPATIONAL PERFORMANCE AND EXERCISE HABITS (PHYSICAL ACTIVITY) IN PORTUGUESE ELITE MALE POLICE OFFICERS

MONTEIRO, L., NUNES, F., OLIVEIRA, P., LANHAM, S.N., THRUSTON, J., ABEL, M.G.

UNIVERSIDADE LUSÓFONA, LISBON

INTRODUCTION: Physical fitness and occupational performance are crucial requirements for police officers, especially those in elite units [1,2,3,5]. As such, physical activity and exercise habits are critical factors in maintaining fitness levels. However, the impact of age on these factors in Portuguese elite male police officers is not fully understood. This study aims to investigate the influence of age on physical fitness, occupational performance, and exercise habits in this population.

METHODS: Forty-two trained male elite police officers in Portugal completed a timed occupational-specific circuit, the On-Duty Task (ODT) [4], and a physical fitness assessment, which included shuttle runs, agility T-test, sit-ups, handgrip strength, horizontal and vertical throwing of a 3kg medicine ball, flexibility, and pull-ups. Additionally, the level of physical exercise was assessed using the International Physical Activity Questionnaire (IPAQ), and the importance of characteristics necessary to carry out occupational tasks, simulated through the simplified Borg scale, was also recorded. Elite police officers (CI) were stratified into cut-offs, younger (≤ 38 years; n = 20) and older (≥ 39 years; n = 22) based on the sample mean age. Independent-sample t-test was used to analyze differences in outcome measures between the cutoff values of younger and older officers.

RESULTS: Older elite police officers took 19.5% longer to complete the ODT circuit compared to younger officers (younger: 210.0 s ± 26.7 vs. 251.6 ± 38.8 s; p = 0.001). Both groups reported similar frequencies of vigorous physical activity and showed comparable cardiovascular levels (younger: 50.78 ± 7.18 ml.kg-1.min-1 vs. older: 44.80 ± 6.92 ml.kg-1.min-1, p = 0.065) and handgrip strength (HGS) levels (younger: 54.74 ± 4.70 kg vs. 52.66 ± 10.67 kg; p = 0.391). However, significant differences were found between the two age groups indicating that the younger officers had superior agility (10.83 ± 0.89 vs. 11.67 ± 0.98 s; p = 0.04), abdominal strength (number of repetitions, 52.65 ± 4.86 vs. 43.5 ± 7.34; p = 0.01), arm strength (number of pull-ups, 15.3 ± 5.03 vs. 10.5 ± 3.87; p = 0.001), and arm power (throwing a 3kg medicine ball, 6.29 ± 0.78 m vs. 5.46 ± 0.94 m; p = 0.002). The police officers had some similar aptitude characteristics, but in terms of power and agility, these negatively influenced occupational performance.

CONCLUSION: The study results suggest that age-related declines in physical fitness and occupational performance occur in Portuguese elite male police officers, despite their similar levels of physical activity and training. Law enforcement professionals need to be aware of the potential negative impact of aging on physical performance and adjust training programs accordingly. Further research in this area is necessary to develop effective strategies to mitigate these age-related declines.

PHYSIOLOGICAL CHARACTERISTICS OF THREE LEVELS OF MALE JUDO ATHLETES

HARAT, I., KISLEV-COHEN, R.

WINGATE INSTITUTE

INTRODUCTION: Judo is a combat sport that relies on anaerobic abilities such as strength, power and anaerobic capacity, in addition to grip strength and specific judo technique. The aim of this cross-sectional study was to evaluate the physiological profile of judo athletes from various levels and to identify physiological determinants for judo success.

METHODS: 38 athletes of the men's national judo team, from 3 levels, various weight classes and ages (cadets + Juniors [CJ]: n=14, age=17.04±1.4; Non-Olympic seniors [NOS]: n=20, age=21.6±1.9; Olympic seniors [Oly]: n=4, age=28.6±2.7) were tested for various anaerobic physiological qualities.

The selected tests were: countermovement jump (CMJ), drop jump from a 40 cm box (DJ), maximal grip strength (Grip) and upper body Wingate anaerobic test with a resistance of 6% of bodyweight (WIN). In addition, 5 RM strength measures of 3 exercises (squat, hang power clean and bent-over row) were gathered from the athletes' ongoing strength program.

All measures were normalized for body mass or competition weight class. The dependent variables were world judo ranking and an internal quality ranking based on success in national vs. international competitions.

For CJ, a coach estimated their level (high vs. low level) based on success in national competitions alone since these young athletes were yet to compete at international level. A comparison was also made between the three age categories.

RESULTS: While some significant differences were found between groups (CMJ peak power, grip strength, WIN peak power [PP], WIN mean power [MP] and strength levels), most between-group differences disappeared when normalized. The only remaining significant differences were WIN test relative PP (p=0.022) and relative MP (p=0.001). Post hoc analysis revealed a significant difference in relative WIN PP between CJ and NOS (p=0.027) but not between NOS and OLY, and in relative WIN MP between CJ and NOS (p=0.001) and CJ and OLY (p=0.039), but not between NOS and OLY. No differences were found in any of the variables between success levels in CJ. Since OLY contained only 4 athletes, this comparison was made for all seniors (NOS + OLY), with no differences found between national and international level senior athletes.

CONCLUSION: It was not possible to differentiate high vs. low level athletes in our cohort. When comparing the three groups, only WIN relative PP and relative MP were significantly different between groups while other measures lost significance when normalized. This strengthens the notion that anaerobic power and capacity are relevant to judo. Success in Judo is multifaceted. Future studies should further explore relevant judo physiological tests, including aerobic capacity, with a greater sample of elite athletes, while considering non-physiological factors (e.g. psychological and technical) as significant determinants of success.

EFFECT OF FITNESS ON TIME COURSE OF RECOVERY FOLLOWING ACUTE STRENGTH AND AEROBIC CONDITIONING TRAINING

GRAMMENOU, M., KENDALL, K.L., WILSON, C.J., PORTER, T., LAWS, S.M., HAFF, G.G.

EDITH COWAN UNIVERSITY

INTRODUCTION: Contemporary athletes are dealing with highly congested training and competition schedules. Therefore, their ability to recovers as fast as possible is a crucial component for performance enhancement and maintenance. Multiple factors have been proposed to modulate the time-course of recovery following a single training session with fitness being an important one. Currently, the majority of athletes are required to develop multiple physical capacities in order to compete at high level. In this instance, to successfully evaluate fitness, we may need the creation of a of a metric incorporating multiple physical performance qualities. The primary aim of this study was to examine the impact of fitness described by a total fitness score (TFS), which was defined as the average score of maximal aerobic capacity, handgrip strength score and 10 repetition maximum score, on the time-course of recovery following acute bouts of resistance (STR) and high-intensity interval training (HIIT) training.

METHODS: Twenty-eight resistance-trained males and females participated in a randomised cross-over designed intervention to examine the time course of recovery following acute STR and HIIT sessions, where on separate occasions participants undertook either a STR or HIIT session divided into 8 testing sessions across 14-17 days. The isometric mid-thigh pull (IMPT), countermovement jump (CMJ) and modified Wingate test (WINmod) were performed at baseline, immediately post-exercise, as well as at 6- and 24-hours post-exercise. Total work was calculated by multiplying the force applied by the distance over which the force was applied.

RESULTS: Following a resistance training session, it was reported that jump height was significantly supressed for up to 24 hours compared to baseline (p=0.0012). However, when participants were grouped based on their TFS there was a main effect of group (F2,15=5.27, p=0.02). Specifically, it was found that people possessing a higher fitness score were had a lower decrease in jump height immediately post-exercise compared to both medium (p=0.018, g=-0.67 [-1.62,0.28]) and low group (=0.011, g=-0.64 [-1.56, 0.28]). Additionally, people in the high TFS group had a significantly higher jump height compared to people in the low group 6-hours post-exercise (p=0.018, g=0.85 [-0.09, 1.80] and they slightly surpassed their baseline performance, but it was not statistically significant (g=0.10 [-0.82, 1.03]).

CONCLUSION: Based upon the current findings, it seems that higher fitness levels, as described by the current composite score used may prevent acute fatigue following a resistance training session. Additionally, it may speculated that people with higher fitness scores may be able to potentiate their explosive strength within the first 6-hours following a resistance

training session, as depicted in changes in jump height, further supporting the hypothesis that fitness may be an important regulator of time-course of recovery but more research is warranted.

CP-MH04 Cardiovascular diseases I

COMBINED EFFECTS OF ACUTE AEROBIC EXERCISE BEFORE OR AFTER STRETCHING ON ARTERIAL STIFFNESS

OI, N.
OSAKA INSTITUTE OF TECHNOLOGY

INTRODUCTION: Increased arterial stiffness enhances cardiovascular disease risks. Aerobic exercise or stretching generally decreases arterial stiffness, but resistance exercise does not. Arterial stiffness changes are also affected by the exercise order in combined exercise. For instance, aerobic exercise after resistance exercise improves arterial stiffness, but resistance exercise after aerobic exercise didn't. Although both aerobic exercise and stretching improve arterial stiffness, the exercise orders and combined effects on arterial stiffness are still unclear. Thus, this study aimed to investigate the combined effect of aerobic exercise before and after stretching on arterial stiffness.

METHODS: Fourteen healthy young males (21 ± 1 years) participated in five trials in random order on different days; 1) seated resting trial (REST); 2) aerobic exercise-stretching trial (AERO-ST); and 3) stretching-aerobic exercise trial (ST-AERO); 4) aerobic exercise trial (AERO); 5) stretching trail (ST). A cycling ergometer exercise of 20 min at the intensity of 120 beats/min of heart rate levels was performed as an aerobic exercise, and four types of stretches of 20 min focusing on the lower limbs were performed. Before (Pre) and immediately (Post) after trials, cardiac ankle vascular index (CAVI) and carotid-femoral pulse wave velocity (cfPWV) were measured to evaluate arterial stiffness.

RESULTS: CAVI and cfPWV were not significantly different in the comparison of Pre in each trial. Pre and Post1 of CAVI values were compared for each trial; REST and ST showed no significant differences, whereas AERO-ST, ST-AERO, and AERO showed significant reductions (AERO-ST, Pre, 6.2 ± 0.5; Post1, 5.5 ± 0.6 %, ST-AERO, Pre, 6.1 ± 0.5; Post1, 5.6 ± 0.6 %, AERO, Pre, 6.3 ± 0.5; Post1, 5.6 ± 0.4 %, both $P<0.01$). However, the reductions in these trials were comparable. The cfPWV results showed a significant decrease in AERO-ST, ST-AERO, and AERO from Pre to Post1 change and no difference among these trials as well as CAVI results. (AERO-ST, Pre, 5.9 ± 0.3; Post1, 5.7 ± 0.3 %, ST-AERO, Pre, 6.0 ± 0.5; Post1, 5.7 ± 0.3 %, AERO, Pre, 6.0 ± 0.4; Post1, 5.8 ± 0.3 %, both $P<0.01$).

CONCLUSION: Our findings indicate that both single aerobic exercise and combined aerobic exercise before or after stretching would acutely reduce arterial stiffness. However, exercise order and combined effects of aerobic exercise and stretching would not differ among degrees of arterial stiffness reduction.

SCREENING YOUNG ATHLETES – CAN WE IGNORE THAT A NEGATIVE STANDALONE HISTORY & PHYSICAL EXAMINATION COULD SKIP HIGH RISK CARDIAC CONDITIONS ?

STOIAN, I.M.1, IONESCU, A.2, STOIAN, I.3, GEORGESCU, M.2
1 EMERGENCY INSTITUTE OF CARDIOVASCULAR DISEASES "PROF DR CC ILIESCU", BUCHAREST, ROMANIA 2 NATIONAL INSTITUTE OF SPORTS MEDICINE, ROMANIA 3 NATIONAL INSTITUTE FOR RESEARCH IN SPORT, ROMANIA

INTRODUCTION: Pre-Participation (PPE) cardiovascular (CV) screening in young athletes is the cornerstone of any evaluation for detecting high-risk CV (hrCV) conditions responsible for sudden cardiac death (SCD) linked with exercise.(2,5) Sometimes, the PPE-CV protocols rely on the standalone History&Physical (H&P),such as the 14-Element AHA Recommendation.(4) Less apparent hrCV conditions may not be readily evident by standalone H&P (1); the association with resting electrocardiography (ECG) and echocardiography (ECHO) is mandatory for the correct diagnosis.

Retrospective study of PPE-CV athletes:To compare the standalone H&P (14-Element) with ECG and ECHO results, recorded for each athlete, according to the protocol. To evaluate the incidence of false positive (positive: >/equal 1 of the 14-Elements) (4) and false negative H&P vs ECG/ECHO data.

METHODS: Retrospective 6-year (2016-2021) study of 385 highly trained athletes (ath)-football .

Study Group:211 ath (100% males;17-37 yo); 178 (84.4%) caucasians, 33 (15.6%) afroamericans. All underwent PPE before competitions. Standard PPE included H&P, ECG (3) and ECHO (5).

RESULTS: Height 174+/-2 cm; Weight 78+/-1 kg; BSA 1.94 m2;BP 125+/-5 mmHg.

211 ath: 191 (90.52%),normal H&P and ECG; 4(1.89%) positive H&P; 16(7.6%) normal H&P and borderline ECG (in time,1 Brugada type I, 3 WPW). ECHO:200(94.7%) normal with normal H&P and 11 (5.3%) abnormal with 4 positive H&P: 2 hypertrophic cardiomyopathy, 2 right ventricular dilation, 1 abnormal origin of coronary artery, 1 dilated cardiomyopathy, 3 stenotic bicuspid aortic valve, 2 mitral prolapse. Coronarography, cardiac MRI indicated accordingly.

CONCLUSION: In most cases, standalone H&P correlated with ECG and ECHO , but failed to identify hrCV entities responsable for SCD in 11(5.31%; 1 Brugada, 3 WPW, 7 abnormal ECHO). No false positive H&P. Asymptomatic rare cardiac conditions are sometimes overlooked by standalone H&P.

Conclusions. PPE-CV screening for identifying hrCV conditions shall include ECG/ECHO.

THE ROLE OF PHYSICAL ACTIVITY PROGRAM IN ANTIHYPERTENSIVE DRUG CONSUMPTION: A RANDOMIZED CONTROL TRIAL

DI MARTINO, G., DELLA VALLE, C., CENTORBI, M., BUONSENSO, A., IULIANO, E., FIORILLI, G., DI CAGNO, A., CALCAGNO, G., DI COSTANZO, A., KOMICI, K.

UNIVERSITÀ DEGLI STUDI DEL MOLISE

INTRODUCTION: Physical activity (PA) improves hypertension control and may reduce the consumption of antihypertensive drugs. However, the effect of exercise training on systolic blood pressure remains under- studied especially among hypertensive populations in relationship to commonly used antihypertensive drugs. Aim of the study was to evaluate the effect of a 24 months supervised program of PA on drug load in hypertensive subjects without previous major cardiovascular diseases (CVDs).

METHODS: A randomized controlled, parallel-group, observer-blinded clinical trial has been designed. Hypertensive subjects at risk of CVDs taking at least one drug were enrolled. A total of 180 participants were randomized and 111 participants completed the 24-month assessment. Participants were randomly allocated to an intervention group (EG) (n=90) that underwent to a 24-month supervised program of physical activity or to a control group (CG) (n=90). The EG underwent a PA program of increasing intensity, duration and frequency 3 times/week. The CG followed a program of postural PA. Outcome measures were evaluated at 0, 6, 12, 18 and 24 months. The drug load in each participant was calculated by summing the ratios between the prescribed daily dose (PDD) and the defined daily dose (DDD) for all antihypertensive drugs taken by the participants.

RESULTS: At baseline, the two groups were homogeneous in terms of age, diastolic and systolic pressure, and PDD/DDD. At 24-month assessment, Repeated Measures Analysis of Variance (RM-ANOVA) showed significant differences between the two groups in PDD/DDD ($p < 0.05$).

CONCLUSION: We demonstrated that a PA program supervised by personal trainers reduces drug consumption in elderly with hypertension with or without previous CVD.

HEAT THERMOTHERAPY TO IMPROVE CARDIOVASCULAR FUNCTION: A SYSTEMATIC REVIEW AND META-ANALYSIS

PRICE, B.S.1, LUCAS, S.J.E.1,2, AKERMAN, A.P.3, GIFFORD, R.E.1, LUCAS, R.A.I.1

[1 2] UNIVERSITY OF BIRMINGHAM., [3]ULTROMICS LTD, OXFORD

INTRODUCTION: Heat thermotherapy (HT) is a passive heating intervention that is associated with reduced cardiovascular disease (CVD) risk and improved cardiovascular (CV) function. Despite several mechanistic reviews, longitudinal and experimental studies, it is unclear whether HT consistently improves CV function. This systematic review and meta-analysis aimed to determine the efficacy of HT to improve CV function.

METHODS: In a registered systematic review (CRD42020193669), databases (Embase, Medline and Web of Science) were searched up to March 2022 for HT studies investigating CVD-related outcomes, including systolic (SBP), diastolic (DBP) and mean arterial (MAP) blood pressure, flow-mediated dilation (FMD), peripheral artery shear rate (SR) and arterial stiffness. Study inclusion criteria was adults aged >18yrs, a passive heating stimulus with no exercise involved and a control group comparison. Of 3074 papers screened, 41 papers were included in the meta-analysis. Studies were separated into two categories, acute (1 heating bout) and chronic perturbation (>1 heating bout), permitting examination of physiological changes immediately after a single HT bout vs possible functional and structural CV changes after multiple HT bouts. Effect estimates were calculated using generic inverse variance and random effect models with pooled effects presented with 95% confidence intervals. Estimated significance (α>0.05) and heterogeneity (I^2) were examined. Pre-planned subgroup analyses compared the effects of modality (sauna, water-perfused suit, hot water immersion), health status (healthy, unhealthy) and time (session duration × bouts).

RESULTS: Compared with control conditions, HT reduced DBP (acute: n=20, -2.2 mm Hg [-4.0, -0.5], I^2= 75%; chronic: n=7, -4.8 mm Hg [-7.2, -2.4], I^2= 33%), MAP (acute: n=16, -4.9 mm Hg [-7.5, -2.3], I^2= 53%), FMD (acute: n=12, 0.3 g [0.1, 0.6], I^2=0%) and SR (acute, n=14, 3.7 g [2.3, 5.2], I^2=0%; all p<.05). There was no difference in arterial stiffness (p>.53; I^2=0%). Subgroup analysis indicated an acute heating modality effect for FMD (p=0.01; I^2=22%) and DBP (p<0.01; I^2=96%), such that DBP was reduced to a greater extent by sauna, followed by hot water immersion (-6.9 mm Hg [-15.9, 2.1] vs -4.3 mm

Hg [-9.2, 0.5]). There were insufficient studies to conduct subgroup analyses on the chronic effect of heating modality. Subgroup analysis for participant health status or time showed no acute or chronic HT effects for CV outcomes (all p>.05). Risk of bias assessment indicated that 35/41 papers had some concerns, and 6/41 papers have a high risk of bias.

CONCLUSION: This meta-analysis indicates that HT provides clinically meaningful improvements in CV outcomes both acutely and chronically. Such CV improvements appeared unaffected by an individual's health status or HT intervention duration. Acutely, sauna may be the most effective HT modality to elicit CV changes. These data support evidence for HT as a method to improve CV health.

ACUTE RESPONSES AND CHRONIC ADAPTATIONS ON CARDIOVASCULAR AND NEUROMUSCULAR OUTCOMES OF ENDURANCE AND RESISTANCE EXERCISE WITH BLOOD FLOW RESTRICTION IN PEOPLE WITH HYPERTENSION: A SYSTEMATIC REVIEW.

RIVERA-MEJÍA, S.L., CAMACHO-VILLA, M.A., GIRÁLDEZ-GARCÍA, M.A., CASTRO-ESTRAVIZ, P., CARBALLEIRA, E.

UNIVERSITY OF A CORUNA

INTRODUCTION: Regular phsical exercise is an effective strategy for reducing blood pressure (BP) with similar efficacy to medication. Recently, exercise with blood flow restriction (BFR) has emerged as a potential therapeutic tool for individuals with hypertension (HT) [1]. However, is needed to establish the FITT-VP (frequency, intensity, type, time, volume, progression) parameters that lead to a balance between minimizing risks and maximizing gains, such as improvements in cardiovascular (CV) and neuromuscular (NM) health. This review aimed to synthesize the available scientific evidence concerning the cardiovascular and neuromuscular responses and adaptations from endurance (EE), resistance (RE), and combined exercise with BFR in individuals with HT. The secondary objective was to describe the technical aspects of BFR and FITT-VP parameters that may impact the outcomes observed.

METHODS: A systematic search using terms as exercise type, BFR, and HT in PubMed, Web of Sciences, SPORTDiscus, Scopus, CINAHL, and MEDLINE databases was completed in June-2022 according to PRISMA statement. We selected quasi-experimental, randomised, and non-randomised control trials, that assessed the acute or chronic effects on CV and NM outcomes. The protocol was registered at PROSPERO (ID: CRD42022338515)

RESULTS: In total, 536 articles were identified, of which 11 studies (134 participants) were included. Specifically, 8 articles evaluated the acute CV effects of BFR, with 6 studies involving BFR applied to RE (20-80% 1-RM), and 2 studies incorporating BFR with EE (30-40% of VO2max). BFR interventions showed not statistically significant differences in the increments of heart rate and BP during exercise and returned to pre-exercise values in the post-exercise phase (i.e., after 60 min), compared to non-BFR interventions.

Regarding chronic effects of BFR applied to RE, 3 studies showed significant reductions in systolic blood pressure (SBP) (~12 mmHg) when utilizing BFR with low-intensity RE. However, no studies investigating adaptations from BFR with EE, or the response/adaptation of NM outcomes were found. Information regarding the progression parameter was not available.

Occlusion pressure was established based on either arterial occlusion pressure (AOP) (40-100%), or SBP (70-130%). Studies lacked sufficient information respect to the measurement position of AOP or cuff characteristics.

CONCLUSION: Our findings indicate that short-term exercise with BFR appears to be safe and may confer potential long-term benefits for individuals with HT. Nevertheless, to ensure accurate and reproducible results, detailed descriptions of the FITT-VP parameters and the methodology of BFR application, should be provided.

A CONSUMER WEARABLE ACTIVITY TRACKER-BASED BEHAVIOUR CHANGE INTERVENTION IMPROVES SEDENTARY BEHAVIOUR AND CARDIOVASCULAR HEALTH IN SEDENTARY ADULTS: A RANDOMISED CONTROLLED TRIAL

FRANSSEN, W.M.A., NIESTE, I., JORIS, P.J., VANDEREYT, F., SAVELBERG, H.H.C.M., EIJNDE, B.O.

HASSELT UNIVERSITY

INTRODUCTION: To investigate the effectiveness of consumer wearable activity trackers (CWATs) as self-monitoring tool (CWAT-only) and as part of a multiple behaviour change technique (self-monitoring + motivational counselling) to reduce sedentary behaviour and improve cardiovascular health in sedentary adults.

METHODS: In a three-armed randomised controlled trial, 59 (male/female: 21/38) sedentary adults (sitting time of ≥ 9h/day; age: 53.3 ± 8.7 years; BMI: 26.0 ± 4.1 kg/m2) were randomly allocated to a control group, a CWAT-only group or the CWAT+ group (CWAT + motivational interviewing) for 12 weeks. Physical activity (PA) and SB were assessed using the activPAL3™ accelerometer. In addition, anthropometrics, plasma lipids, systemic inflammation and markers of microvascular endothelial function, blood pressure, heart rate variability (HRV) and vascular endothelial function were assessed at baseline and after the 12-week intervention period.

RESULTS: As compared with the control group, the CWAT+ group significantly reduced time spent in sedentary behaviour (-81 min/day confidence interval [CI; 95%]: [-151, -12] min/day; p = 0.021) and significantly increased step count (+3117 [827, 5406] steps/day; p = 0.036), standing time (+62 [14, 110] min/day; p = 0.015), light intensity PA (LPA; +28 [5, 50] min/day; p = 0.040) and moderate-to-vigorous PA (MVPA; +22 [4, 40] min/day; p = 0.005). Measurements of were all significantly increased, compared to the control group.

CONCLUSION: A 12-week multiple behaviour change intervention (self-monitoring + motivational interviewing) is effective to significantly reduce sedentary time and increases physical activity. These changes in sedentary behaviour and physical activity improve triglyceride concentrations and HRV in sedentary adults.

DOES UNDERWATER MASSAGE ENHANCE THE BENEFITS OF HOT WATER IMMERSION?

CULLEN, T., MENZIES, C., STEWARD, C.J., THAKE, C.D.

COVENTRY UNIVERSITY

INTRODUCTION: There is emerging evidence that demonstrates the health benefits of passive heating including improvements to cardiovascular health and reductions in stress and anxiety[1]. Many commercially available hot tubs offer underwater massage systems which purport to enhance any benefits of hot water immersion and increase enjoyment. However, the potential benefits of additional underwater massage have yet to be studied.

METHODS: Participants (16 male, 4 females) completed three, 30-minute sessions of hot water (39°C) immersion with underwater air jet massage (Air jet), water jet massage (Hydro jet) and no massage (Control) in a randomized and counterbalanced order on separate days.

Cardiovascular responses comprising; heart rate, blood pressure and femoral artery blood flow and shear rate were measured. Stress responses comprising; state trait anxiety, basic affect, and salivary cortisol were recorded before and after each trial. Enjoyment was assessed using a modified version of the physical activity enjoyment scale [2]. Data were analysed using a mixed effects model.

RESULTS: Post immersion, heart rate increased ($P<0.001$, mean difference 31bpm) with no difference between conditions. Systolic and diastolic blood pressure both decreased immediately post hot tub (approximately 9 and 19 mmHg respectively), with the decrease in systolic blood pressure being greater in the Air jet Vs Control condition ($P=0.007$, mean difference= 6.4 mmHg). Blood flow and total shear rate of the superficial femoral artery increased immediately following hot tub immersion ($P<0.0001$). The increase in blood flow was greater in the Control condition compared to the Air jet condition ($P=0.009$, mean difference 147 ml/min). Similarly, the increase in total shear rate was less in Air jet condition compared to the Control condition ($P=0.009$, mean difference 3380 s-1). Anxiety and salivary cortisol were reduced following hot tub sessions ($P=0.0035$, predicted difference 3.25 AU, 10.3% and $P=0.014$, predicted difference 3.02 nmol/L, 21.3% respectively) but did not vary between conditions. There was no effect on basic affect. Enjoyment did not vary between conditions.

CONCLUSION: These data confirm the positive acute responses to heat therapy by hot water immersion on markers of cardiovascular health, anxiety, and stress. However, there was no additional benefit of underwater massage irrespective of whether the massage was delivered by air or water jets.

QUANTITATIVE COMPARISON OF SPINAL KINEMATICS IN SQUAT WITH VARYING LOAD WEIGHT

SHOJI, K., NAKAYAMA, K., SHIOUCHI, M., MANABE, Y.

CHUKYO UNIVERSITY

INTRODUCTION: The human spine, composed of 33 vertebral bones, has mobility, such as extension-flexion and rotation, similar to other joints. However, most biomechanical motion studies of squat simplify the human trunk to a single rigid-body segment, ignoring its range-of-motion (ROM). This study utilized a trunk model with six rigid-body segments and quantitatively compared spine extension movements during squat with varying load weight.

METHODS: Twelve healthy young males participated in this study. Each participant performed squat with varying load weight (60, 70, 80, 90%1RM: one repetition maximum). A three-dimensional optical motion capture system (VICON MX) with 12 cameras was used for the experiment. Twenty-seven reflective markers were attached to landmarks on the participants' bodies; six markers were located on the tips of specific spinous processes, thus creating a two-dimensional trunk model with six rigid-body-segments in the sagittal plane. Accordingly, the total and regional ROMs were evaluated using the angular displacement between each segment. A one-way repeated measure analysis of variance (ANOVA) was performed to detect differences in the total and local ROMs due to differences in load weight. Differences in the total and regional ROM between load weight were measured with Bonferroni's multiple comparison analyses.

RESULTS: Total ROM of spine in the squat was more flexed than at the neutral position (spine angle in the standing posture) in all load conditions. The one-way ANOVA test revealed that total ROM of spine in the high load conditions was

significantly more flexed position than in the low load conditions (at 60 to 100% normalized time, P <.05). The differences in regional ROM of spine, when varying load weight, were significant at the lower regions of the spine (T12: at 40 to 100% normalized time, L3: at 40 to 100% normalized time, respectively; P <.05).

CONCLUSION: Concerning spinal kinematics in squat, we conclude that (1) flexion ROM was larger with increasing load weight, and (2) the difference in regional ROM, with increased load weight, were especially remarkable around the upper lumbar spine.

HIP EXTENSION MOMENT IN BODYWEIGHT BULGARIAN SQUAT IS PREDOMINANTLY CAUSED BY PASSIVE REACTION MOMENT DERIVED FROM REAR FOOT GROUND REACTION FORCE NOT FROM UPPER BODY WEIGHT

ARAKAWA, H., NAKASHIMA, H., TANIMOTO, M.

INTERNATIONAL BUDO UNIVERSITY

INTRODUCTION: The rear-foot-elevated split squat, usually called the Bulgarian squat (BSQ), is known to be useful for developing hip extensor muscles compared to conventional two-legged squat. A recent study suggested that in BSQ, the passive reaction moment derived from the rear foot ground reaction force (RFGRF) may contribute as resistance to hip extension moment of front leg. The aim of this study was to quantify the contribution of RFGRF to the resistance to hip extension moment in BSQ for different stance width and trunk angle conditions and compare them with the reaction moment derived from upper body weight.

METHODS: Thirteen young male participants performed bodyweight BSQ in total six conditions with two different stance widths (wide and narrow) and three different trunk forward lean angles. The trials performed voluntarily at each stance width were regarded as normal trunk lean angles, and the trials were also performed at each ± 10° trunk lean angles (trunk forward and upright). Feedback was provided to the subject to ensure that the amount of forward displacement of the knee during the BSQ was identical among the different trunk lean conditions. Prior to the data collection, a four-week familiarization period was conducted to allow subjects to familiarize with each condition. An optical 3-D motion capture system (VICON) and two force platforms (Kistler) for each leg were used for data collection. Based on the 2D inverse dynamics, net hip extension moment of front leg, reaction moment derived from RFGRF, and reaction moment derived from upper body weight were calculated using MATLAB (MathWorks). Each value at the lowest position of BSQ was used for evaluation.

RESULTS: The time course of net hip extension moment of front leg was approximately synchronized with the sum of reaction moments derived from RFGRF and upper body mass, demonstrating validity of the current biomechanical analysis. The mean values of reaction moment derived from RFGRF were 76 Nm, 79 Nm, and 86 Nm for wide stance, and 49 Nm, 67 Nm, and 71 Nm for narrow stance conditions (the orders were trunk forward, normal, and upright, respectively). Contribution ratio of the reaction moment derived from RFGRF to the sum of reaction moments (i.e., RFGRF and upper body mass) were 70%, 80%, and 96% for wide stance, and 59%, 78%, and 96% for narrow stance conditions (in the same order).

CONCLUSION: Resistance to hip extension moment in bodyweight Bulgarian squat is predominantly caused by passive reaction moment derived from RFGRF, not from upper body weight. The finding of this study suggests that more attention should be paid to the contribution of RFGRF when performing BSQ as a hip extensors dominant resistance exercise.

THE EFFECTS OF A 6-WEEK OF VELOCITY-BASED TRAINING ON RECREATIONAL LIFTERS

KIM, J.1,2, PARK, J.1,2, KANG, J.1,2, PARK, S.1,2, YOON, S.1,2

KOREA NATIONAL SPORT UNIVERSITY

INTRODUCTION: Recently, a new training method called velocity based training (VBT) has been introduced to compensate for the disadvantages of percentage-based training (PBT) [1,2]. VBT is a method of evaluating the velocity of concentric contraction through displacement and time by attaching an accelerometer to a barbell or body, and is known as a method of improving muscle power by objectively confirming the intensity and amount of training through velocity [3]. So far, various studies on VBT have been conducted, but only general 1RM measurements have been performed, and no study has verified the difference in kinetics and kinematics of the effect of VBT. Therefore, this study aims to further clarify the effect of training by verifying the differences in kinetics and kinematics during 6 weeks of velocity-based training.

METHODS: Eight recreational lifters who have more than 1 years athletic career and had no experience of musculoskeletal injuries on lower extremities in the last six months(age: 29±3.81 yrs., height: 174±3.83 cm., body mass: 74±11.63 kg.,) participated in this study. All subjects were asked to perform back squats with 1RM before and after a 6-week velocity-based training. Three-dimensional motion analysis with 8 infrared cameras (sampling rate: 100 Hz) and 3 EMG channels (sampling rate: 1,000 Hz) was performed to investigate the training effect. A paired t-test was used to find out the significances and the significance level was set at .05.

RESULTS: As a result of this study, significantly increased ankle and knee joint ROM were found in descending and increasing phase of sagittal plane, respectively (p<.05). In addition, significantly reduced quadriceps muscle activation was found in all phases (p<.05). Finally, there was increase in mass of back squat 1RM after the training.

CONCLUSION: The results of this study suggest that 6 weeks of velocity-based training allows recreational lifters to perform the efficient back squat with less agonist muscle activity.

SECONDARY JUMP DIRECTION AFFECTS LOWER LIMB KINEMATICS IN LANDING TASK

BRUNETTI, C.1, RABELLO, R.1, PELLEGRINI, A.1, BERTOZZI, F.2, SFORZA, C.1

1 UNIVERSITÀ DEGLI STUDI DI MILANO, MILAN, ITALY; 2 POLITECNICO DI MILANO, MILAN, ITALY

INTRODUCTION: ACL injury is one of the most burdensome injuries in sports [1]. Non-contact ACL injury mechanism includes extended knee, valgus stress, and anterior tibial shear forces [2]. To prevent these injuries, athletes' biomechanical deficits are often assessed through functional tasks. They often include a single-leg landing followed by secondary jumps [3]. This study aimed to analyze 3 tasks, comparing secondary jump's effects on the whole first-landing kinematic time series.

METHODS: 28 females and 29 males (18-30 years, 2+ weekly trainings, no lower limbs injuries in the last 6 months, no knee injury history) performed 3 unilateral drop-jump variations, with a secondary jump in vertical (DV), 45° medial (DM) or lateral (DL) direction, executed with the dominant limb. The box-target distance was 60% of the maximal forward jump, and the box's height was 20% of the subjects' height. A 9-camera optoelectronic system provided frontal and sagittal plane lower limb kinematics, from initial contact to maximum knee flexion (landing phase, LP). One-way ANOVA through SPM and post-hoc analyses (Bonferroni correction) were used to compare the task kinematics along the normalized LP curves (alpha=0.05).

RESULTS: ANOVA revealed significant differences among tasks in all kinematic variables. DL had the highest hip adduction and ankle eversion, while DM showed the lowest in the whole LP. DL required higher knee adduction, but only in 0-9% of LP. DL had the highest hip flexion for the whole LP, while DV had the lowest in the early LP stages. All tasks showed similar knee flexion, but DV presented slightly lower knee flexion than DM only in 0-18% and 75-100%. The ankle dorsiflexion was lower in DV than in the other tasks.

CONCLUSION: Hip and ankle frontal plane kinematics were highly task-dependent, most notably at early LP stages, the high-risk window for ACL injury. Moreover, the subjects exhibited a more flexed lower limb and dorsiflexed ankle in DL and DM, plausibly to move forward the body and promote the secondary 45° jumps execution. As expected, the secondary jumps affected the first-landing kinematics, even if subjects were instructed to land with the same technique in all tests. The present results demonstrated how different secondary jump strategies, applied to a standard drop jump task, may change lower limb kinematics in athletes.

THE USE OF A CONVENTIONAL DROP LANDING TASK TO IDENTIFY STABILITY DEFICITS IN NETBALL PLAYERS WITH FUNCTIONAL ANKLE INSTABILITY.

KWONG, D., OLIVIER, B., GREEN, A.

UNIVERSITY OF JOHANNESBURG

INTRODUCTION: A common practice to highlight deficits in postural stability associated with ankle injury, has utilised the forward vertical drop landing task. A systematic review of 149 drop landing studies indicated, more than 50% of drop landing tasks provided no specific rationale for the selection of a vertical drop-landing task, which challenges the validity in sport specific translation (1). Functional ankle instability (FAI) is associated with impaired postural control and may indicate deficits resulting in injury during landing tasks (2). The need to determine if dynamic postural stability indices (DPSI) are sensitive to functional ankle instability (FAI) during common landing tasks is warranted (3). The study aimed to determine possible differences in DPSI between an FAI group and healthy group, with a frontal and lateral 40cm landing task.

METHODS: A cross-sectional within-subjects repeated measures design was implemented on a purposive sample of twenty-one university league netball players. The sample included 9 FAI (age 20.68 ± 2.01 year, height 174.36 ± 4.72 cm, weight 67.17 ± 9.51 kg) and 12 healthy (age 20.34 ± 2.07 year, height 173.76 ± 5.72 cm, weight 68.12 ± 7.21 kg). Participants performed frontal and lateral drop landings from 40 cm box onto a 60 by 40 cm triaxial force-platform (Bertec Corp, Columbus, OH), sampling at 1000Hz. DPSI were calculated with a cut-off of 3 seconds after initial plate contact (4). The use of the idFAI questionnaire, categorized the participants into FAI and healthy groups (5).

RESULTS: The FAI group displayed the following stability indices for the frontal plane: ML indices: 0.05 ± 0.01; AP: 0.06 ± 0.2; Vertical: 1.27 ± 0.35; DPSI: 1.12 ± 0.14, peak BW force: 3.59 ± 0.87. Lateral plane indices presented: ML: 0.07 ± 0.03; AP: 0.05 ± 0.01; Vertical: 1.28 ± 0.16; DPSI: 1.18 ± 0.21, peak BW force: 4.62 ± 0.87. There were no significant differences in stability indices between the FAI and healthy groups for the frontal and lateral landing tasks.

CONCLUSION: The lack of significant differences between FAI and healthy group stability indices would suggest that the 40cm drop protocol may not be as translatable to sporting demands as previously thought. The intensity and reactive components experienced on the netball court is more likely to lead to stability deficits that are more noticeable . The need

for more dynamic protocols are warranted to ensure that no neuromuscular aspects are been overlooked by common landing tasks. The development of valid and reliable dynamic versions of the these tasks may yield results that are more representative. Furthermore, coping mechanisms in the lower kinetic chain may mask deficits in DPSI due to the controlled nature of the task.

THE EFFECTS OF DIVIDED ATTENTION AND DECISION-MAKING ON SINGLE-LEG LANDING STABILITY IN ELITE YOUTH FOOTBALL PLAYERS

FRIEBE, D., GIESCHE, F., BOTH, H., HASER, C., PFAB, F., SIELAND, J., WILKE, J., BANZER, W.

GOETHE-UNIVERSITÄT FRANKFURT

INTRODUCTION: In football, athletes are required to quickly adapt their motor actions to the dynamics on the field. Previous studies have shown that athletic high-speed tasks (e.g., cutting or landing) involving either divided attention or time-constrained decision-making result in aberrant move-ment biomechanics associated with an increased risk for lower limb injuries. However, the effects of both cognitive components combined are largely unclear. Thus, the aim of this study was to investigate the effect of divided attention and decision-making on single-leg landing stability in elite youth football players.

METHODS: Twenty-one male elite youth football players (17.5±0.5years) performed a total of 24 counter-movement jumps with single-leg landings on a pressure plate. Of those, n=6 were anticipated without visual distraction (control condition 1), n=6 anticipated with visual distraction (control condition 2), and n=12 unanticipated with visual distraction (experimental condition). Jump order was randomized. During the flight phase, the participants had to perceive and react to a game situation (movement of two opponents, two teammates), which was displayed on a screen in front of them. In the unanticipated condition, the landing leg had to be selected based on the movement of the opponents. In the control conditions, the landing leg was indicated before the jumps. In the conditions with divided attention (control 2 and experimental), participants had to register the movement of teammates (visible only during flight phase) and report it after landing. Biomechanical stability outcomes were vertical peak ground reaction force (pGRF; [N]), time to pGRF [ms], and center of pressure path length (COP, [mm]). Recall error rate (incorrect perception of the teammate movements, [%]) was assessed to quantify divided attention performance. To test for differences between conditions, repeated measures ANOVA were used for landing stability outcomes and Wilcoxon-tests for recall error rates.

RESULTS: We found main effects (condition) for pGRF ($p<0.001$, eta2=0.37), time to pGRF ($p<0.001$, eta2=0.36) and COP ($p<0.001$, eta2=0.34). Post-hoc tests indicated significantly higher pGRF, and COP values as well as shorter time to pGRF in the unanticipated condition compared to the control conditions 1 and 2 ($p<.05$). However, visual distraction alone (control 2) did not result in differences in landing stability ($p>.05$). Finally, compared to the anticipated jumps, the unanticipated condition resulted in a higher recall error rate (z=-3,1; p =.002) indicating impaired divided attention perfor-mance under time constrains.

CONCLUSION: The combination of time-constrained decision-making and visual distraction may cause poten-tially harmful lower limb biomechanics and erroneous visual perception during jump-landings. These changes do not seem to occur with divided attention tasks only. This may have relevant implications for injury prevention in elite football players.

RELIABILITY AND KINEMATICS OF MOVEMENT CONTROL TEST IN THE HIP JOINT

CHEN, C.Y.

NATIONAL YANG MING CHIAO TUNG UNIVERSITY

INTRODUCTION: Neuromuscular control of the hip joint has been linked to lower extremity alignment and injury. Neuromuscular performance can be examined clinically using physical examination or using laboratory tests such as electromyography or motion analysis systems. A series of kinetic control tests has been proposed in 2012 and widely used these days. However, measurement reliability and validity of these tests are still unclear. The aims of the study were to determine the reliability and the validity (using the kinematic data collected during the test) of the hip kinetic control tests.

METHODS: Asymptomatic adults were recruited for the study. Four testing tasks were performed including hip flexion control, adduction control, internal rotation control and external rotation control, and the movement was videotaped for scoring. During the task, kinematics data was also collected by VICON motion analysis system. The movement testing was scored by three trained therapists, and the patients were divided into pass or fail group based on the average score. The hip kinematics were then compared between the two groups. The measurement repeatability of kinetic control tasks was calculated using the kappa statistic and Fleiss kappa statistic, and the differences of kinematics data were assessed using the independent T test.

RESULTS: The intra-rater measurement reliability of the kinetic control testing was 0.333-1 and the inter-rater reliability was between -0.108-0.55. There was no significant statistical difference in kinematics data (0.07 CONCLUSION: Base on the

data so far, it indicated poor measurement reliability of the kinetic control tests and failed to validate the kinetic control testing results using the hip kinematics results. One possible reason for poor testing repeatability might relate to the multiple components of these tests. Poor measurement reliability and insufficient grouping level (only two groups in our design) might account for failure to show the validity of the kinetic control tests. In addition, we were unable to rule out possible influence from poor control of the trunk or other parts of the lower extremity such as ankle and knee joint. Future research should take into account these factors and re-assess the usefulness of the kinetic control tests as a neuromuscular control test battery.

KNEE AND HIP BIOMECHANICS IN SINGLE LEG HOP FOR DISTANCE IN HEALTHY AND ACL RECONSTRUCTED SOCCER PLAYERS: WHEN THE HOPPED DISTANCE IS NOT ENOUGH

BALDAZZI, A., JACQUES, J., RUM, L., BORZUOLA, R., PILLET, H., MACALUSO, A., MARGHERITINI, F., BERGAMINI, E.

UNIVERSITY OF ROME "FORO ITALICO

INTRODUCTION: A widely used test to determine readiness to return to sport (RTS) after ACL injury and surgery is the Single Leg Hop (SLH) (1). However, when proposing SLH, several works focus only on the knee, not considering a whole-body approach including the hip, which plays a key role. The aim of this study is twofold: to assess i) hip and knee differences in kinematic/kinetic parameters between healthy and ACL reconstructed soccer players, and, as consequence, ii) possible relations between SLH distance (performance-related indicator) and lower limb trend associated with poor neuromuscular control.

METHODS: Five healthy (27±6 y; 74.3±6.5 kg; 1.82±0.04 m) (HC) and three soccer players with ACL reconstruction (24±4 y; 83.6±7.6 kg; 1.83±0.04 m; 8-12 months post-surgery) (ACLR) participated in the study. Three SLH trials were performed for each limb [1], landing on a force plate (AMTI, USA, 1000 Hz). The 3D trajectories of 52 markers were measured by an optoelectronic system (Vicon, UK, 200 Hz) [2]. A time window of 100 ms after the foot landing was considered and joint kinematic and kinetic parameters were extracted together with the hop distance. To investigate the presence of asymmetries between injured and non-injured (or dominant Vs non-dominant in HC) sides, the Limb Symmetry Index (LSI) was calculated for each parameter. Significant differences between HC and ALCR were investigated using an unpaired t-test or the Mann-Whitney test, according to data distribution.

RESULTS: Internal knee extension moments were significantly lower in ACLR than HC (2.9±1.4 Vs 3.7±0.9 Nm/kg, $p=0.02$). In contrast, hip flexion moments were higher in ACLR than HC (9.2±2.2 Vs 6.9±1.6 Nm/kg, $p<0.001$). From a kinematics point of view, the two groups did not display significantly different strategies ($p>0.05$). Interestingly, when considering asymmetries between the two body sides, LSI values of the hop distance were the same for both ACLR and HC (97%), suggesting readiness for RTS in ACLR. Conversely, LSI values for knee adduction were doubled in ACLR than HC (211±2% Vs 102±42%), indicating a higher knee instability in the frontal plane for ACLR.

CONCLUSION: The results of this preliminary study confirm that considering only the between-side symmetry of the hop distance as a criterion for RTS clearance is not recommended. Symmetry in hop distance, in fact, can be reached even when a high asymmetry is displayed in the knee adduction movements, indicating that knee instability may still be an issue. The ACLR and HC soccer players implemented different landing strategies, especially from a kinetics point of view, at both knee and hip joints, suggesting a pre-planned protective strategy to decrease moments and loads on the injured knee and, possibly, compensate for knee instability at the hip joint [1,3].

PERONEAL MUSCLE RESPONSE TO AN EXPECTED AND UNEXPECTED FALL IN YOUNG AND MIDDLE-AGED ADULTS BEFORE AND AFTER NEUROMUSCULAR TRAINING: A CROSS-SECTIONAL STUDY

HAYEK, R., GOTTLIEB, U., GUTMAN, I., SPRINGER, S.

FACULTY OF HEALTH SCIENCES, DEPARTMENT OF PHYSICAL THERAPY, THE NEUROMUSCULAR & HUMAN PERFORMANCE LABORATORY, ARIEL UNIVERSITY, ARIEL, ISRAEL

INTRODUCTION: During middle age (MA), balance and postural control may be affected by age-related changes in the nervous system and by a decrease in muscle mass, strength, and flexibility. The aim of this study was to investigate the anticipatory response of the peroneus longus muscle (PL) to landing after an expected fall (jump) and its postural response to an unexpected fall (perturbation) in MA and young adults. A second aim was to investigate the influence of neuromuscular training on PL postural responses in both age groups.

METHODS: Twenty-six healthy MA (55.3±4 years) and 26 healthy young adults (26.3±3.6 years) participated in the study. Assessments were performed before (T0) and after (T1) PL EMG biofeedback (BF) neuromuscular training. To assess the PL response to the expected fall, subjects performed a single-leg drop jump, and the PL EMG activity in preparation for landing (PL activity as % of jump time) was calculated. PL time to onset and time to peak were measured to assess PL response to an unexpected fall (perturbation). In this test, subjects stood on a custom-made trap door that produced a sudden 30° ankle inversion. For the excepted fall, repeated measures ANOVA was used to analyze PL EMG activity in preparation for

landing (% of jump time), and for the unexpected fall, MANOVA for repeated measures was performed to evaluate the effects of age and EMG-BF training on unexpected fall performance (PL onset time and time to peak).

RESULTS: Before training, the MA group showed significantly shorter PL activity in preparation for landing compared to the young adults (25.0% vs. 30.0%, p=0.016), while after training there was no difference between the groups (28.0% vs. 29.0%, p=0.387). There were no differences between groups in peroneal activity after the unexpected fall before and after training.

CONCLUSION: Our results suggest that automatic anticipatory peroneal postural responses are decreased at MA, whereas reflexive postural responses appear to be intact in this age group. A short PL EMG-BF neuromuscular training may have an immediate positive effect on PL muscle activity at MA. The results may highlight the need to examine both anticipatory and reflexive muscle responses when studying age-related changes and the necessity of studying middle-aged adults. Furthermore, this should encourage the development of specific interventions to ensure better postural control in this group.

EFFECTS OF VARIOUS BAT WEIGHTS ON BAT SWING SPEED AND LOWER EXTREMITY MUSCLE ACTIVATION OF COLLEGIATE BASEBALL PLAYERS

LU, S.D., HO, C.J., HUANG, B.X., LIN, Y.A., LIN, J.Z.

NATIONAL TAIWAN UNIVERSITY OF SPORT

INTRODUCTION: Different bats may provide different batting performances, and improving swing speed is commonly considered to be the general consensus among outstanding hitters in baseball (1). Thus, the action of swinging a bat involves skill. In addition, to strengthen their muscles and be successful baseball players, athletes must train intensively. In terms of their joints, the player must coordinate the muscles of the entire body; muscle activation is crucial during the swing phase (2), which can help baseball players improve their batting performance. The purpose of this study was to investigate the swing process for different bat weights on the baseball field and analyze the bat speed and lower extremity muscle activation during the swing phase.

METHODS: The study participants included three university baseball players. The participants would hold 800, 850, 900, and 950g bats and swing at a ball on a tee. Every swing was performed three times, aiming to bat the ball from the tee into a net (87cm x 87cm). As experimental equipment, a Vicon motion analysis system, 9 wireless EMG, and 2 force plates were used. The swing action was divided into wind-up, stride, start-up, swing, contact, and follow-through. The statistical mused was One-way repeated measures ANOVA.

RESULTS: The results show that the swing speed with the 800g bat was significantly higher than with the 950g bat (P=.010). In terms of the characteristics of lower extremity muscle activation with different bat weights, the results show that gastrocnemius activation was significantly higher with the 850g bat than with the 800g bat (P=.043). Gastrocnemius activation with the 900g bat was significantly higher than that with the 850g bat (P=.038).

CONCLUSION: From the results, a significant difference was found between the swing speed of the 800g and 950g bats, indicating that, the higher the bat's mass and the further the bat mass is distributed from the rotation axis, the higher the resistance to angular acceleration, which reduces bat control (3). With a relatively lightweight bat, the resistance to angular acceleration is lower, so the bat is easier to control. A lightweight bat may require less muscle activation to control the swing motion. Regarding muscle activation according to swing phase, gastrocnemius muscle activation was significantly higher at start-up when the player was holding a 900g bat than with an 850g bat; gastrocnemius activation with the 850g bat was significantly higher than with the 800g bat, showing that baseball batting is a process of the continuous action of joints. They must add more power when swinging a heavier bat. In the rest of the swing phase, no significant difference was found between the different bat weights and the degree of muscle activation, indicating that when choosing a bat, the batter should choose the bat that is suitable according to their ability, function, and muscle strength.

CAN INSTRUMENTED MOUTHGUARD BE USED FOR COMPUTING HEAD INJURY CRITERIA FOR RUGBY COLLISION INVESTIGATION OVER ELITE PLAYERS ?

BOURGAIN, M., GUERRERO, M., PETETIN, M., ROUILLON, O., PROVOT, T., VALDES-TAMAYO, L.

INSTITUT DE BIOMÉCANIQUE HUMAINE GEORGES CHARPAK

INTRODUCTION: Using instrumented mouthguards for quantifying head acceleration during rugby games is promising for better understanding concussion occurrence [1]. However, defining a threshold for rugby is an issue. Several criteria were proposed for several [2] purposes but none were defined for rugby. Thus the objective of this study was to investigate if classical injury criteria are of interest for collision investigation in rugby based on instrumented mouthguards (iMG) measurements.

METHODS: A call for volunteers was done over a male team of under 21 years old rugby players. They were equipped by instrumented mouthguards (boil and bite technology, Prevent biometrics) during their trainings. Collision selection threshold was set as 5g and then 10g over a 50ms window. Data were compared to video in order to eject false positive data. Eight different common injury criteria were computed on this dataset: GAMBIT, CP, HIC, RIC, PRHIC, HIP, BRIC and BrIC. Associated tolerance thresholds were computed.

RESULTS: Over the 16 players who were asked to be part of the study, 15 volunteered. iMG were used during 8 training sessions and 7 official matches, corresponding to 1169 collisions. With a threshold set as 5g, there was 81% of true positive, 13% of false positive and 6% undetermined. With a threshold set as 10g, results were 93%, 4% and 3% respectively.

Among those, 25 impacts were associated to at least over one injury criteria and 2 were over 2 injury criterias. The BrIC criteria was the one conducting to the highest percentages of severity overtaking.

CONCLUSION: Instrumented mouthguards seem to be a promising tool for measuring in-field head accelerations. Those may be of interest for coaches and medical staff to adapt players trainings for reducing their injury risk. However, current injury criteria were not created for rugby purposes and its choice highly influence computation output. Criteria may use linear and/or rotational components of measured head accelerations, and here, the one presenting the highest risk of being overtaken was based on rotational components. Unfortunately, data selection on the device is based on translational acceleration which may conduct to bias selection.

To conclude, this study highlight the interest of defining a proper injury criteria for rugby by presenting the high influence of criteria choice. Thus, a large scale study should be conducted to define criteria and threshold for helping staff to understand at-risk movements and eventually to better understand concussion occurrence.

BIOMECHANICAL ANALYSIS OF VOLLEYBALL SPIKE ACCORDING TO TAKE-OFF STYLE OF RECREATIONAL PLAYERS

CHOI, W., KANG, J., PARK, J., KIM, J., PARK, S., YOON, S.

KOREA NATIONAL SPORT UNIVERSITY

INTRODUCTION: In the volleyball game, spike is one of the most dynamic motions and an important scoring technique. Since a high jump height can provide various attack routes, it is known as a very important factor that can improve a players offensive ability during spikes (1,2). South Korea, where recreational volleyball club league is very active, many recreational players are trying to perform spike movements like professional players. It is, however, difficult to obtain helpful information of spike because most of the preceding studies have been conducted on professional players. Therefore, the aim of this study was to find out the biomechanical differences between take-off style during the volleyball spike motion to provide useful information for improving the spike motion of club players.

METHODS: Twelve healthy male adults(age: 23.4±1.7 yrs, height: 178.7±5.7 cm, weight: 77.1±13.8 kg, career: 5.8±2.1 yrs) who had no experience of musculoskeletal injuries or surgery within the past six months were participated in this study. They were asked to perform spike movement of both hop-step style jump(HSJ: jumping after both feet touch the ground at the same time) and a closed-step style jump(CSJ: jumping after both feet touch the ground with a slight difference in time). A 3-dimensional motion analysis with eight infrared cameras(sampling rate: 100Hz), an eight-channel wireless electromyography(sampling rate: 1,000Hz), and two force plates(sampling rate: 1,000 Hz) was performed to examine the differences. The paired t-test was performed to find the significance and the statistical significance level was set at α=.05.

RESULTS: HSJ revealed significantly increased vertical COM velocity and left biceps femoris and medial gastrocnemius activation compared with those of CSJ in the approaching phase. CSJ also showed significantly increased horizontal COM velocity and right rectus femoris compared with those of HJS in all phases. In addition, CSJ revealed significant increased tibialis anterior muscle activation compared with HSJ in approach phase. Finally CSJ showed increased right biceps femoris, left biceps femoris and medial gastrocnemius activation in take off phase, respectively. For CSJ, significantly increased the maximum horizontal ground reaction force was found in right foot than that of HSJ.

CONCLUSION: he results of this study are expected to provide information on the difference in take-off style to volleyball club members and life sports leaders through the quantification of spike motion according to the two take-off style and to contribute to improvement of the spike skills of club members in the future.

FORCE ACCURACY AND JOINT POSITION SENSE IN KICKING AND SUPPORTING LEG OF KNEE EXTENSORS IN FOOTBALL PLAYERS

TSVETKOVA-GABERSKA, M.

SOUTH-WEST UNIVERSITY

INTRODUCTION: The proprioception plays an important role in neuromuscular control and properly maintaining joint stability, especially in dynamic sports related with accurate dosing and reproduction of force such as football (1). The as-

sessment of the force sense (FS) and joint position sense (JPS) in active and passive mode, as well as their relationships connecting interlimb strength asymmetry (ISA) between the kicking (KL) and supporting leg (SL) in football players are less investigated (2). This study aimed to assess FS, JPS and ISA and the correlations between them in the KL and SL in football players.

METHODS: The FS, JPS and maximal isometric voluntary contraction (MIVC) of knee extensors were measured by isokinetic dynamometer (Biodex 4Pro) in 11 footballers (age 24±4 years) in an university football team. MIVC was measured in Nm at 90o position of the knee joint and further also used as a target of reproducing 50% self-estimated effort during FS testing. JPS was measured at 90o starting positon to target angles - 40o and 65o (active and passive), without feedback. The ISA was calculated as percentage difference between the torque of the stronger versus the weaker knee extensors. Descriptive statistics and Mann-Whitney test were used to assess the differences of mean±SD for all variables. Correlations were calculated with Pearson coefficient ($p<0.05$). The performance in the force and joint position matching tasks were determined by the absolute error (AE), as a measure of accuracy. It was calculated as absolute deviations from a target, and obtained through the arithmetic mean of the individual errors in the modulus (3).

RESULTS: The MIVC values (Nm) for extensors of KL and SL were :257±42 and 253±42, respectively. In 45% of the football players was found ISA above 10%. There was no linear correlations between: JPS with FS in KL or SL; AE of FS in KL; AE of active JPS in 40o and 65o in KL or SL; AE of passive in 40o and 65o in SL. High positive correlation ($r=0.86$; $p=0.0003$) was established between AE of FS of the extensors of SL and ISA, i.e. the players who achieved higher force accuracy with extensors of SL have lower strength asymmetry. A moderate negative correlation ($r=-0.53$; $p=0.005$) was found between AE of KL at 40o passive JPS and ISA, i.e. the players who attain better JPS accuracy of KL have higher bilateral strength asymmetry.

CONCLUSION: This study presents evidence that reveals differences in proprioceptive senses between extensors of KL and SL and their relationship with ISA, which are in accordance with their different role in the football game. This specificity is probably related to adaptation changes in the proprioceptive motor control, which are provoked by the unilateral demands in football.

KINETIC ADAPTATIONS MEASURED WITH INSTRUMENTED FOOTBALL SHOES DURING AN EXHAUSTIVE ON-FIELD RUN

KARAMANOUKIAN, A., BOUCHER, J.P., LABBE, R., VIGNAIS, N.

UNIVERSITÉ PARIS SACLAY

INTRODUCTION: Fatigue and excessive training load have been identified as major injury risk factors in football [1]. However, most of research in this field has been conducted in laboratory conditions, due to the lack of a portable device allowing kinetic assessment.

METHODS: Ten amateur football players performed an exhaustive run at a constant velocity corresponding to 90% of their maximal oxygen consumption on a turf football pitch. Each participant was wearing an instrumented football shoe (Phyling, France) recording vertical ground reaction forces (vGRF) [2]. Kinetic parameters (maximal force -Fzmax, vertical and leg stiffness -kvert and kleg, loading rate -LR, high frequency forces -HFF) and temporal parameters (duty factor -DF, time of maximal force -tFzmax, step frequency -FREQ) were extracted for each step. A cluster analysis (Random Forest Algorithm) was conducted based on differences between the non-fatigue condition and the fatigue condition, corresponding to the first and last 10% of the run, respectively. The cluster classification was validated by a leave-one-out cross-validation (LOOCV). Paired-sample t-tests (and Cohens d) were used to find differences in the fatigue related changes at group level (all participants) and cluster-level.

RESULTS: Mean time to exhaustion was 548 ± 147s, and 766 ± 206 steps were analysed (per participant). Cluster analysis identified two clusters (C1, n=7 and C2, n=3, LOOCV = 100%). Statistical analysis at the group level revealed a significant decrease for Fzmax ($p<0.05$), a significant increase for DF ($p<0.05$) and tFzmax ($p<0.05$) between the non-fatigue and the fatigue conditions. Cluster analysis revealed a significant increase among C1 subjects for HFF ($p<0.05$), DF ($p<0.05$) and tFzmax ($p<0.05$) and a significant decrease for Fzmax ($p<0.001$), kleg ($p<0.001$) and kvert ($p<0.001$). On the contrary, C2 participants showed significant increase for kleg ($p<0.05$) and kvert ($p<0.05$). Effect size was large (>0.8) for each analysis.

CONCLUSION: Kinetic adjustments induced by fatigue were detected in situ using an instrumented football shoe. To the best of our knowledge, this is the first study to analyse kinetic parameters directly in the field, thus contributing to ecological validity. Individual analysis also revealed different strategies among participants, which reinforces the need of injury prevention programs based on individual investigation. Further research is now needed to understand how these different strategies may affect the risk of injury in soccer.

DIFFERENCES IN KINETIC FACTORS RELATED TO LATERAL CUTTING PERFORMANCE WITH AND WITHOUT COGNITION

ONO, K.1, NAKATANI, K.1, TANIGAWA, S.2

UNIVERSITY OF TSUKUBA

INTRODUCTION: Ball games require players to react and feint against opponents and the ball, and especially in basketball, the players frequently perform fast lateral moves. In addition, since the players must change their actions in response to the surrounding situation, they must move laterally with cognition. Although previous studies have investigated kinematic factors related to fast lateral cutting, no studies have investigated kinetic factors and included cutting tasks with cognition. Therefore, this study aimed to identify differences in kinetic factors related to fast lateral cutting with and without cognition.

METHODS: Fifteen male basketball players performed lateral cutting tasks with a turn in conditions with and without cognition (cognitive cutting: CC, non-cognitive cutting: NCC). Three-dimensional coordinates and ground reaction force were collected, and we calculated the lateral cutting index (LCindex) and net internal joint torques of the lower extremities during the turning phase in each condition. We calculated the LCindex by dividing the center of gravity velocity at take-off during the turning phase by the ground contact time. We considered the LCindex as an outcome reflecting the cutting performance, and a greater LCindex means better cutting performance.1 Paired t-tests were used to compare the LCindex between each condition. Pearson's correlation coefficient was used to examine the relationship between the LCindex and peak joint torque in each condition ($p < 0.05$).

RESULTS: There was no significant difference in the LCindex between conditions (CC vs. NCC: 4.97 ± 1.14 vs. 5.01 ± 0.75, mean ± SD). In the CC condition, there were significant correlations between LCindex and peak ankle plantarflexion (value +/-: -, r = -0.64), knee varus (+, r = -0.52), and internal rotation (+, r = 0.53) torques. In the NCC condition, there were significant correlations between the LCindex and peak hip extension (-, r = 0.53), internal rotation (+, r = -0.54), and external rotation (-, r = 0.53) torques.

CONCLUSION: Although this study revealed no difference in the LCindex between each condition, the kinetic variables related to the LCindex differed by the effect of cognition. It is possible that while hip variables are mainly important in the planned conditions, the cognitive condition requires faster reaction and force exertion, thus increasing the importance of ankle plantarflexion torque. As the results indicate that the force exertion characteristics required during the lateral cutting task could differ due to the cognition involved, the findings of this study could contribute to a better understanding of how to consider more practical training.

PITCH VELOCITY AND MUSCLE ACTIVITY DURING SUPRA-MAXIMAL EFFORT PITCHING IN JUNIOR HIGH SCHOOL BASEBALL PLAYERS.

OKEGAWA, T.

THE UNIVERSITY OF TOKYO

INTRODUCTION: On the sports field, athletes exert their maximal effort to perform at their best. However, even when they think they have exerted their maximal effort, their performance may not be up to par. Therefore, the ability to exert ones maximal effort as aimed is important for athletes. Compared to top athletes, less skilled athletes, such as children, may not have a superior ability to exert their own maximal effort. In baseball pitching, ball velocity is one of the most important performance indicators, and a high ball velocity greatly enhances competitive advantage. In this study, ball velocity and muscle activity were recorded during supra-maximal effort pitching by junior high school baseball players in order to measure the ability of less-skilled baseball players to exert their maximal effort.

METHODS: Junior high school baseball players were asked to throw 8 pitches each at 110% and 120% of subjective effort after 8 pitches at 100% of subjective effort, and the electromyographic (EMG) activity was recorded. Participants threw balls toward a net set up 5 m away. EMG data were collected using a wireless surface EMG system (Trigno wireless EMG system: Delsys Inc., USA). EMG sensors were attached following muscles: biceps brachii (BB), triceps brachii (TB), ulnar carpal flexor (FCU), extensor carpi radialis (ECR) of the throwing arm, rectus femoris (RF), biceps femoris (BF), tibialis anterior (TA), and soleus muscle (SOL) of both legs. Two high-speed cameras (DSC2 RX10M4: SONY, Japan; 960 fps) were used to capture the ball trajectory. Ball velocity was defined as the magnitude of the velocity vector at ball release and was calculated from the center of the ball in the high-speed camera images digitized by automatic image recognition technology (DeepLabCut).

RESULTS: Ball velocity increased at 110% or 120% of subjective effort pitching compared to 100% of subjective effort pitching. Muscle activity of the muscles for which EMG was recorded in this study did not change with effort level.

CONCLUSION: To clarify the ability to exert maximal effort, ball velocity and muscle activity in supra-maximal effort pitching was investigated. As a result, ball velocity increased at supra-maximal effort pitching, but muscle activity did not change. The result of ball velocity suggests that junior high school baseball players are not successfully exerting their maximal effort. The EMG result suggests that the increase in ball velocity during supra-maximal effort pitching may not be due to simple muscle exertion, but rather to more efficient proximal-to-distal energy transfer. As the participants in this study were junior high school students, the current results may not apply to athletes at different levels, such as high school, college, and professional players. Proficiency may be related to the ability to exert maximal effort. Therefore, if highly skilled players are instructed to throw a supra-maximal effort pitch, their ball velocity may not change.

EFFECTS OF INDIVIDUALIZED VERSUS STANDARDIZED DROP JUMP TRAINING ON PHYSICAL FITNESS IN YOUTH VOLLEYBALL PLAYERS

HAMMAMI, R., GABOUJ, M., KASMI, S., REBAI, H., DUNCAN, M., GRANACHER, U.

TUNISIAN RESEARCH LABORATORY SPORTS PERFORMANCE OPTIMISATION

INTRODUCTION: When performing DJs, the selection of appropriate drop-heights is important for two reasons. First, adequate drop heights enable individuals to maximize training-induced physical and physiological adaptations and thus performance enhancement (Taube et al., 2012). Second, adequate drop heights prevent mechanical stress through excessive loads on lower extremity muscle-tendon and bony structures (Peng et al., 2011, Wallace et al., 2010). With regards to the training specificity concept (Behm and Sale, 1993), training has to closely mimic the demands of competition (Behm & Sale, 1993), which is why training using high and low DJ heights have become popular means in (plyometric) jump training (Ramirez-Campillo et al., 2019). However, there is hardly any information available in the literature regarding the effects of drop-jump training using maximal height (individualized DJ training) in comparison to the standardized DJ training in youth athletes. Therefore, the objective of this study was to examine the effects of individualized drop jump training (IDT) using individualized drop height versus standardized training (SDT) on components of physical fitness in youth volleyball players.

METHODS: Thirty male youth volleyball players, aged 12 to 13 years, performed either an individualized or a standardized drop jump training. Both interventions lasted for 8 weeks with two weekly sessions. While the individualized exercise group (IDT) performed drop jump exercises using a drop height according to the individual's maximal rebound jump height, the standardized exercise group (SDT) performed drop jumps from a 30-cm drop box height. Pre- and post-training, drop jump performances from 20, 30, and 40-cm drop heights were assessed. Dynamic balance was tested using the Y-balance test, linear sprint speed using 5, 10 and 20-m sprint times, and change-of-direction speed using the T-test.

RESULTS: Significant group-by-time interactions were found for drop-jump, balance, and sprint tests ($p < 0.0001$; $P\eta 2$ range from 0.14 to 0.67) but not for CoD speed. Post-hoc tests showed significant improvements in favor of the IDT group for all drop jump heights ($P\eta 2 = .910$, $p = .0001$, $\Delta = 6.7\%$), 5-m ($P\eta 2 = .558$, $p = .003$), 10-m ($P\eta 2 = .681$, $p = .01$, $\Delta = .012$ %), 20-m ($P\eta 2 = .683$, $p = .01$, $\Delta = .24\%$) sprint times. Main effects for time identified similar pre-post improvements for dynamic balance and CoD speed in both IDT and SDT groups (all $p < 0.05$).

CONCLUSION: Findings revealed that IDT was more effective than SDT to improve drop jump performance and linear sprint speed. Due to the importance of vertical jumps and short accelerations for overall competitive performance in volleyball, our results suggest that young volleyball players should perform IDT as part of plyometric training if the goal is to improve acceleration and vertical jump performance.

PHYSICAL LITERACY AND PHYSICAL ACTIVITY IN SWEDISH PRESCHOOL CHILDREN – A CROSS-SECTIONAL STUDY

DERAKHTI, M.

INSTITUTION OF SPORTS SCIENCES

INTRODUCTION: There are substantial evidence for the numerous positive health benefits of physical activity (PA) [1]. At the same time, PA-levels in European and Swedish children are insufficient [2]. Inadequate PA-levels, and associated non-communicable diseases, are regarded as one of the most significant public health challenges confronting us. Hence, it is important to understand how we can promote ways for children to reach adequate PA-levels. Physical Literacy (PL), a theory with potential benefits for PA-behaviors and health, has garnered increasing attention over the last few years. Encompassing physical, affective, and cognitive dimensions PL is often described as an individual's capacity, confidence, and motivation to partake- and engage in PA [3]. The early childhood years are suggested for PL promotion since this period is regarded as crucial for PA-behaviors, future health, and the opportunity to reach most children via school settings. However, the assessment and status of PL in young children, specifically in Sweden, is at best scarce. Consequently, research is required to assess PL and its connection to PA-levels in young Swedish children.

METHODS: The data for this study will be derived from hip-worn accelerometers (GT3X+, Actigraph) worn for 7 days to assess PA-levels, as well as a modified version of the Canadian Preschool Physical Literacy Assessment to assess PL. The study will include 412 preschool children, aged 3-6, from 20 preschools. The data will be analyzed and presented via descriptive statistics, and multi-level linear regression models will be used to determine associations between total- and intensity stratified PA-levels and PL.

RESULTS: Tentatively, the results of this study are expected to provide: 1) a picture of PL and PA in Swedish preschool children and the connection therein; 2) much-needed data for the fields of PL and early childhood research; 3) Indications on effectiveness of PL for promoting PA; and 4) guidance for future research in PL.

CONCLUSION: With individual, and public health advancements in mind, there is ample reason to enhance our understanding of the relationship between PL and PA-levels of Swedish preschool children, as well as, adding data to the PL-field. The present study has the potential to contribute to these objectives.

ENERGY AND MACRONUTRIENT INTAKE OF JAPANESE ELEMENTARY SCHOOL STUDENTS PARTICIPATING IN SPORTS ACTIVITIES.

KOMORI, Y., KATAYAMA, M., KUROTOBI, S., SHIMOYAMA, A., HARA, M., SANADA, K.

KYOTO KOKA WOMENS UNIVERSITY

INTRODUCTION: Adequate energy and nutrient intake during growth and development is necessary for meeting the daily minimum energy requirements, and for supplementing stored energy that is needed for physical growth. Furthermore, energy and nutrient intake must be sufficient to provide the additional energy that is consumed during exercise.

The International Olympic Committee (2014) introduced the concept of relative energy deficiency in sports (RED-S). RED-S can lead to problems with growth and development, metabolism, mental health, cardiovascular health, bone health, and can lead to poorer athletic performance.

The Japan Sport Association (2021) issued "Guidelines for sports activities in the developmental period," which highlights the importance of psychological and social aspects, adequate nutrition, and sports injury prevention. Nutritional considerations indicate sufficient nutrition, and a well-balanced diet are required for physical growth. Additionally, some reports suggest that adequate daily energy intake is important to combat RED-S in adolescent athletes.

The purpose of this study was to examine energy and macronutrient intake of elementary school students participating in sports activities and contribute to healthy sports life management during the early growth and development.

METHODS: Thirty-one elementary school boys (aged 9–12 years), belonging to sports clubs in Shiga-prefecture, Japan, participated in this study. Nutritional intake was investigated using the brief-type self-administered diet history questionnaire for 10-years old (BDHQ-10y, Okuda et al., 2009), and daily intakes of energy, carbohydrates, proteins, fats, vitamins, and minerals were calculated.

The amount of physical activity in a 1-week period was calculated using the International physical activity questionnaire short version (IPAQ-SV, Murase et al., 2001).

Additionally, the participants were divided into 2 groups: high (n = 9, H-PA) and low physical activity (n = 7, L-PA), according to physical activity levels and nutritional intake of each group was compared.

RESULTS: The mean height, weight, and body mass index were 139.9±8.4 cm, 32.0±5.2 kg, and 22.8±2.7 kg/m2, respectively. The daily intakes of energy, carbohydrates, proteins, and fats were 2118.4±766.0 kcal, 303.9±113.7 g, 74.6±31.1 g, and 63.8±25.4 g, respectively. Energy and protein intake was lower than the recommended intake in the Dietary Reference Intakes for Japanese (2020).

Moreover, the H-PA group showed lower energy ($p = 0.09$) and carbohydrate intake ($p = 0.05$) than in the L-PA group.

CONCLUSION: These findings indicate that low energy and inadequate macronutrient intake are prevalent in elementary school boys, particularly, in those with high levels of physical activity.

In conclusion, these results suggest that a dietary intake improvement plan is needed to increase energy and nutrient intake during the developmental period.

VO2MAX PREDICTION FROM SIMPLE VARIABLES IN ADOLESCENTS WITH OBESITY

REY, O., MACCHI, R., NICOL, C., HAYS, A.

AIX-MARSEILLE UNIVERSITY

INTRODUCTION: In recent decades, the proportion of overweight adolescents in the population has been steadily increasing [1]. Overweight is associated with psychological, metabolic and functional complications [2]. Physical activity intervention could improve the health status of these patients and prevent deterioration. In this sense, VO2max is of particular interest to evaluate the physical fitness. While the usual tests are not adapted to obese population, the "Spartacus 15-15" test was developed as an intermittent progressive and maximal running field test more suitable for this population [3]. However, the measurement of VO2max is delicate on the field, requires appropriate device and specific expertise. This study aimed to predict VO2max from simple variables of "Spartacus" test.

METHODS: 44 obese boys and girls (13.4±0.8 yrs; BMI = 34±3.8 kg/m2) performed a Spartacus 15-15 test as previously described [3]. VO2max was quantified from a gas analyser (Cosmed® K4BII). Anthropometric measurements included height, body mass, body max index (BMI), fat and lean mass. Heart rate were recorded (Polar® RS400). The analysis concentrated on the values at rest (HRr), start (HRs), peak (HRp) and mean value (HRm). Peak running velocity was also recorded. VO2max was then predicted using three different models: A linear and non-linear models were performed using a forward regression method to select the model variables. The non-linear functions were chosen from the Akaike information criterion. The third model was an artificial neural network (ANN). The accuracy of the models was compared according to the mean absolute error (MAE) and the adjusted R2.

RESULTS: The average VO2max of the sample was 35.1±4.6 ml/min/kg (CrI 95% = [33.7, 36.5]). ANN was the most predictive model (MAE=1.8 ml/min/kg, R2=0.88) in which anthropometric played a major role. The non-linear model (MAE=2.2 ml/min/kg; R2=0.6) included 5 variables: fat, maximal velocity, HRs, HRr and age. The linear model retained only the variables fat, HRs and HRr variables but had the lowest accuracy (MAE=2.6 ml/min/kg; R2=0.43).

CONCLUSION: This study suggests that the Spartacus 15-15 test is suitable for predicting VO2max. Deep learning model outperforms the classical models but has the disadvantage of being more complex for practitioners to use. More usable models (linear and non-linear) showed acceptable error to monitor physical activity. It is noteworthy that the ANN and non-linear models had a better R2 than the one reported by a previous study, based on a cycle ergometer test [4]. Further analysis will aim to improve the accuracy of the model by considering the HR values at each step of the test and by predicting ventilatory thresholds.

PHYSICAL ACTIVITY INTENSITIES AND COGNITIVE ABILITIES IN ADOLESCENTS: THE ROLE OF CARDIORESPIRATORY FITNESS

ADELANTADO-RENAU, M., MONTEAGUDO, P., MONZONÍS-CARDA, I., MOLINER-URDIALES, D., BELTRAN-VALLS, M.R.

UNIVERSITAT JAUME I

INTRODUCTION: Previous evidence has suggested a positive association between physical activity (PA) and cognition in youth [1]. Likewise, it is well-known that higher levels of PA are associated with improvements in physical fitness in youth, which has also been shown to be positively associated with cognitive function in this population [2]. However, debate continues regarding the influence of the different intensities of PA on these variables. Thus, in this study we tested whether the association between accelerometer-derived PA intensities and cognition in adolescents was mediated by cardiorespiratory fitness.

METHODS: A total of 60 adolescents (17.75 ± 0.29 years; 38.3% girls) were included in the analysis. PA was evaluated by a wrist-worn GENEActiv triaxial accelerometer and expressed as minutes/day of light, moderate, and vigorous PA. Cardiorespiratory fitness was assessed by the 20-m shuttle run test. Cognition was assessed through the Spanish version of the Science Research Associates Test of Educational Abilities which measures verbal ability, numeric ability, and reasoning ability. Boot-strapped mediation procedures were performed and indirect effects with confidence intervals not including zero were interpreted as statistically significant. Analyses were adjusted by sex, pubertal stage, and socioeconomic status.

RESULTS: Our findings suggest that cardiorespiratory fitness acts as a mediator on the relationship between vigorous PA and numeric ability in adolescents (indirect effect = 0.0013 [0.0002; 0.0027]). Specifically, vigorous PA was positively associated with cardiorespiratory fitness (B=0.0172; p=0.0007), which in turn was also positively associated with numeric ability (B=0.0754; p=0.0083). Cardiorespiratory fitness did not mediate other associations between PA intensities and cognitive abilities.

CONCLUSION: Increasing vigorous PA levels may improve adolescents' numeric ability through its positive effects on cardiorespiratory fitness. Our results could aid to design effective physical exercise interventions aimed to enhance cognitive performance in adolescents. Specifically, stakeholders and education professionals should promote vigorous PA to improve both physical fitness and cognitive abilities in youth.

DEVELOPMENT OF CARDIORESPIRATORY FITNESS IN CHILDREN IN THE TRANSITION FROM KINDERGARTEN TO BASIC SCHOOL ACCORDING TO PARTICIPATION IN ORGANIZED SPORTS

RISO, E.M., JÄRVAMÄGI, M., REISBERG, K., JÜRIMÄE, J.

UNIVERSITY OF TARTU

INTRODUCTION: Increasing the time spent in vigorous physical activity (VPA) should be a major goal of PA programs to improve cardiorespiratory fitness (CRF) [1]. PA levels and CRF associate with lower body fatness among children [2]. This study examined the longitudinal development of cardiorespiratory fitness (CRF) in children in the transition from kindergarten to basic school according to participation in organized sports and estimated the associations of CRF and body composition indices during the transition from childhood to preadolescence.

METHODS: Children participated in the three-staged longitudinal study (Kindergarten, 6.6 years, n=212 (110 boys, 102 girls); 1st Grade, 7.6 years, n=136 (70 boys, 66 girls); 5th Grade, 11.5 years, n=142 (72 boys, 71 girls) for 5 years and were categorized into three groups according to participation in organized sports in study period (whole period, episodically, never). Cardiorespiratory fitness was assessed using 20 m shuttle run test, while body composition was measured by skinfold thicknesses and physical activity was registered with accelerometer. International gender- and age-specific CRF reference normatives were also used to characterize participants.

RESULTS: Children who participated consistently in organized sports had significantly higher CRF level and lower body fatness (31.3 ± 13.5 laps in 20 m shuttle run; 21.1 ± 6.3% body fat) in 11.5 years as compared to children who had never participated in sports clubs (20.7±12.0 laps in 20 m shuttle run; 26.1 ± 6.8% body fat). Body composition and CRF did not associate in consistently trained children. The proportion of 5th Grade children demonstrating age appropriate healthy CRF was almost threefold higher in group of consistent sports trainings among both in boys and girls than among non-members of sports clubs.

CONCLUSION: Consistent attendance in organized sports in childhood and early preadolescence ensures higher CRF and more healthier body composition as compared to children who had no experience of organized sports.

RELATIONSHIP BETWEEN GLYCAEMIC CONTROL AND HEART RATE VARIABILITY IN CHILDREN WITH TYPE I DIABETES: A PILOT STUDY

GONZÁLEZ DE RAMOS, C., DÍAZ UREÑA, G., GARCÍA MERINO, S., LÓPEZ NUEVO, C.E., RODRÍGUEZ JIMÉNEZ, C., LÓPEZ BARRENA, N., SAGASTIZABAL-CARDELUZ, B., ALCARAZ, A.

EUROPEAN UNIVERSITY OF MADRID

INTRODUCTION: Diabetes is a significant and chronic condition that occurs when the body cannot produce insulin or produces insufficient insulin, or when it cannot effectively use the insulin it does produce. Type 1 diabetes is the leading cause of childhood diabetes, but it can occur at any age. At the moment, it cannot be prevented. In the Community of Madrid (Spain), it has an incidence of 13.7 cases per-100.000 habitants.

Cardiovascular diseases are the leading cause of morbidity and mortality among diabetic patients (1). Heart Rate Variability (HRV) represents variations between consecutive heart beats (beat to beat or R-R intervals) and has long been used in stratification of the risk of sudden cardiac death and diabetic autonomic neuropathy. (2)

The aim of the study was to analyse heart rate variability in a cohort of children diagnosed with type I diabetes and the relationship with clinical variables such as insulin dose required for diabetes control, as well as time since diagnosis of diabetes or time to 24-hour normoglycaemia.

METHODS: An observational study was carried out with a sample of 14 children between the ages of 6 and 18, diagnosed with type 1 diabetes at the University Hospital of Getafe.

The assessment of the regulation of the autonomic nervous system was performed by measuring heart rate variability. For this purpose, the Firstbeat Bodyguard 2 heart rate monitor will be used for 24-hour recording (3). The HRV measurements performed were: RR intervals (or Normal to Normal-NN intervals), percentage of adjacent NN intervals differing by more than 50 milliseconds (pNN50), root mean square difference of successive RR intervals (RMSSD), low frequency (LF), high frequency (HF) and and Poincaré scatter plot (SD1 and SD2). Spearman´s Rho correlation were calculated among variables. P-value was set at 0.05.

RESULTS: The correlation between HRV variables and clinical data routinely collected in the management of diabetes was studied. A significant correlation was found between time to diagnosis of diabetes and PNN50 (rs=-0.536, p=0.048); RMSSD (rs=0.564, p=0.045), PNN50 (rs=0.597, p=0.031), and SD1 (rs=0.564, p=0.045), with time in normoglycaemic range; LF value (rs=-0.692, p=0.013), with total insulin dose per kg/day; RMSSD (rs=-0.657, p=0.02), LF value (rs=-0.804, p=0.002), HF value (rs=-0.643, p=0.024) and SD1 (rs=-0.657, p=0.02) with total insulin dose per day; and mean HR with PNN50(rs=-0.552, p=0.041) and LF (rs=-0.596, p=0.025).

CONCLUSION: The cohort of diabetic children have a decrease in HRV compared to normative values in healthy children. We found a positive correlation between lower variability as a function of longer time of diagnosis of diabetes and in those children with poorer glycaemic control. Targeted exercise programme could improve autonomic nervous system regulation.

CP-MH06 Cancer I

EFFECTS OF A CLINICAL EXERCISE PROGRAM ON PHYSICAL CONDITION IN LUNG CANCER PATIENTS

GIL-HERRERO, L., CARRASCO-CARRETERO, A.

SPANISH CANCER ASSOCIATION

INTRODUCTION: Lung cancer is the third most frequent type of cancer in Spain after colorectal and breast cancer (1).Thanks to the scientific advancements in diagnostic procedures and treatments of cancer, survival rates in lung cancer patients have increased in recent years. However, there is still a significant percentage of patients who die because of lung cancer, recurrences and metastatic disease. While advanced treatments may increase survival rates, they also present with severe side effects. Some side effects can be treated with additional drugs, but some of them that are not simple to treat and may be chronic problems. For this reason, much attention has been paid to other strategies to reduce these comorbidities like physical exercise (2). This study aimed to report the feasibility of a multi-component exercise program for improving maximal cardiorespiratory fitness (CRF) in lung cancer patients.

METHODS: The study was an uncontrolled trial using a pre-post design with assessment at baseline and post-intervention (12 weeks, moderate to vigorous intensity). It was conducted at the Exercise Oncology Unit of the Spanish Cancer Association in Madrid. All eligible participants provided written informed consent and the study was conducted following the principles of the Declaration of Helsinki. Changes from baseline to post-intervention were analyzed using a paired t-test.

RESULTS: A total of 26 lung cancer patients completed the program and the post-intervention fitness assessment. Participants had a mean age of 60.6±9.2, 77.8% were women and 22.2% were men. In terms of medical data 88.9% had metastatic cancer,45% had surgery and 81.5% were on active treatment(36.4%chemotherapy,13.6%immunotherapy,18.2% targeted therapy,13.6% chemotherapy+ immunotherapy and 18.1% other treatments).

Exercise significantly improved VO2 max by 6.8 ml/kg/minutes($p<.001$),chest strength by 10.7kg ($p<.001$),leg strength by 32.3 kg ($p<.001$),lean body mass by 0.8kg ($p<0.001$),skeletal muscle mass by 0.5kg ($p=.007$),fat mass by -1.3kg ($p<0.001$) % fat mass by -1.7($p<.001$),waist hip ratio by –0.01 ($p=0.039$) and visceral fat area by -7.7($p<.001$).

CONCLUSION: A 12-week, supervised,multi-component exercise program involving moderate to vigorous intensity was found to be feasible and effective for lung cancer patients.

CHANGES IN HEALTH-RELATED FITNESS AND FATTY LIVER INDEX AFTER A 12-WEEK REMOTE EXERCISE INTERVENTION FOR BREAST CANCER SURVIVORS: A RANDOMIZED CONTROLLED TRIAL

MIN, J.1, KONG, I.D.2

1. NATIONAL CANCER CONTROL INSTITUTE, NATIONAL CANCER CENTER, GOYANG-SI, SOUTH KOREA, 2. DEPARTMENT OF CONVERGENCE MEDICINE, YONSEI UNIVERSITY WONJU COLLEGE OF MEDICINE, WONJU, SOUTH KOREA

INTRODUCTION: Exercise, along with other lifestyle modifications, is the most effective ways to manage breast cancer prognosis and recurrence. However, only around 40% of breast cancer survivors have a sufficient physical activity level. In particular, with less face-to-face contact after the COVID-19 pandemic, the decrease in exercise participation is emerging as a critical health problem. Accordingly, the application of remotely delivered exercise intervention is arising as a new alternative, although the efficacy of this method on breast cancer prognosis profiles was not fully understood. Therefore, the purpose of this study is to investigate the efficacy of a 12-week remote exercise program in breast cancer survivors on body composition, fitness, and metabolic profiles.

METHODS: A total of 50 breast cancer survivors (Stage 0-3) were randomly assigned to the exercise or usual care groups (1:1 ratio, mean age 53.9±6.5 years). Participants in the exercise group engaged 3 times per week in an instructional aerobic and resistance exercise program via Zoom (1 session: 30 minutes for 12 weeks). This was combined with unsu-

pervised home-based exercise on other days. The control group was asked to maintain their usual daily activity. The primary outcome was body composition, the secondary outcome was metabolic biomarkers, and the ancillary outcome was fitness parameters.

RESULTS: Among the 50 participants enrolled, 46 (92%) completed the trial with an exercise compliance. While there was no change in body composition factors in the control group for 12 weeks, in the exercise group, these factors improved after 12 weeks($p<0.05$). In addition, there were significant differences and changes between groups in weight($p<0.05$), body mass index($p<0.05$), and waist circumference($p<0.01$). After 12 weeks, there was a significant decrease in a fatty liver index($p<0.01$) in the exercise group, while there was no change in the control group. The exercise group experienced improved flexibility($p<0.01$), muscular strength($p<0.05$), and physical function($p<0.05$) compared to baseline.

CONCLUSION: Implementation of remote exercise intervention significantly improved breast cancer prognosis profile. We believe our study has important implications for understanding the efficacy and possibility of remote exercise as a new approach tool for intervention.

A PILOT RANDOMIZED CONTROLLED TRIAL EVALUATING A COMBINED AEROBIC AND RESISTANCE EXERCISE INTERVENTION IN PATIENTS WITH CANCER

AVANCINI, A.

UNIVERSITY OF VERONA

INTRODUCTION: The association between physical activity and the reduction in mortality and recurrence risk in patients with cancer is gradually consolidating. Exercise has been demonstrated to be an effective strategy in improving quality of life (QoL) and treatment-related side effects. Nevertheless, most patients are insufficiently active, and investigations show that patients compliance and adherence to an exercise intervention are challenging. Therefore, the aim of this study was to investigate the safety and feasibility, and preliminary efficacy of a 12-week combined aerobic and resistance exercise intervention in patients with cancer.

METHODS: A two-site, pilot, randomized controlled trial was carried out, including patients with different cancer types. The exercise intervention consisted of bi-weekly aerobic and resistance training personalized based on patients baseline conditions and preferences. Resistance training comprised body weight or elastic-bands exercises performed in 2-3 sets of 8-12 repetitions, whereas the duration of aerobic component, consisting in walking or cycling activity, training progressively increased over weeks. Both aerobic and resistance activity was performed at moderate intensity and checked using the 10-point Borg Rating of the Perceived Exertion Scale. Patients allocated to the control group received the usual care. The primary study endpoints were safety and feasibility. Safety was assessed using the Common Terminology Criteria for Adverse Events (AEs), whereas the feasibility evaluation included recruitment rate, adherence, and withdrawals. The secondary endpoints were: functional capacity, (Six minutes walking test), muscle strength, (handgrip and leg press test), and QoL, (European Organization for Research and Treatment of Cancer Quality of Life and Core Questionnaire (EORTC- QLQ-C30)). Descriptive statistics and repeated-measures analysis of variance were used to analyze data.

RESULTS: A total of 57 patients (38% recruitment rate; 68% breast, 14% colorectal) were randomly allocated to the intervention (n=37) and controls (n=20). During the 12-week, five dropouts were recorded, three in the intervention (leukemia onset n=1, psychiatric disorder n=1, gonarthrosis n=1), and two in the controls (lack of interest n=2), whereas the adherence to the exercise program was 93%. Three non-severe AEs occurred: n=2, worsening in the lymphedema (Grade 1), and n=1, elbow inflammation (Grade 1). Post-intervention evaluations showed improvements in the exercise group for functional capacity ($p<0.01$), and lower limb strength ($p<0.01$). For QoL, improvements in social function ($p<0.05$), fatigue ($p<0.05$), nausea and vomiting ($p<0.01$), dyspnea ($p<0.05$), insomnia ($p<0.05$), and loss of appetite ($p<0.01$) were observed.

CONCLUSION: Combined aerobic and resistance training is safe and feasible in patients with cancer, with improvements in physical fitness parameters and QoL.

FUNCTIONAL CAPACITY, MUSCLE STRENGTH, BODY MASS INDEX, AND QUALITY OF LIFE IN PATIENTS WITH CANCER: A REAL-WORLD EXPERIENCE

BORSATI, A., CIURNELLI, C., COLONNA, A., D'AMICO, I., DANIELE, A., DEL BIANCO, N., TONIOLO, L., BELLUOMINI, L., LANZA, M., PILOTTO, S., SCHENA, F., AVANCINI, A.

UNIVERSITY OF VERONA

INTRODUCTION: Patients with cancer may experience a series of adverse effects related to the disease or treatments that collectively lead to a worsening quality of life (QoL). Exercise by alleviating some of the side effects and improving physical fitness is considered an important tool that can improve cancer patients' QoL. Additionally, QoL is an important predictor of patient survival. To our knowledge, little data are available about the association between physical fitness and patients' QoL. The present study aims to explore the associations between the components of physical fitness and QoL in a sample of patients with different types of cancer.

METHODS: A cross-sectional design was applied. Patients recruited at the Oncology Unit in the Verona Hospital underwent a series of assessments: (i) anthropometric measures, i.e., body mass index (ii) functional capacity, with the "Six minutes walking test" (6MWT), (iii) muscle strength, through the handgrip strength and the leg press strength tests, (iv) QoL, using the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire (EORTC QLQ C-30). Descriptive statistics, such as mean, standard deviations (or median and interquartile range), frequencies and percent-

ages, were applied to present data. Additionally, Pearson correlation was used to explore the association between physical fitness parameters and QoL domains.

RESULTS: Between 2019 and 2022, 164 patients with cancer were recruited. Overall, 71% were female, 45% had breast cancer, 14% pancreatic cancer, and 39% had metastatic disease. Regarding physical fitness, the mean values were: 512.12 meters (±95.81 meters) for 6MWT, 29.37 kilograms (±8.60) for right handgrip strength, 28.25 (±8.40) kilograms for left handgrip strength, 87.04 kilograms (±52.24) for leg press strength and 26.29 kg/m2 (±5.33) for body mass index. Correlation analysis showed that higher physical functioning was associated with a better 6MWT (r=0.458; p<0.001), right handgrip strength (r=0.217; p<0.001), and left handgrip strength (r=0.185; p=0.01). A higher 6MWT was correlated with a greater role functioning (r=0.258; p<0.001), global health status (r=0.279; p<0.001), and a reduction in dyspnea (r=-0.259; p<0.001), and insomnia (r=-0.259; p<0.001). Greater handgrip strength was associated with better cognitive functioning (right arm r=0.188, p=0.01; left arm r=0.18, p=0.02) and a lower pain level (right arm r=-0.187, p=0.01; left arm r=-0.241, p<0.01).

CONCLUSION: Preliminary results of our study suggest that better physical fitness is associated with a greater QoL and a lower level of symptomatology such as insomnia and dyspnea.

TREADMILL RUNNING SUPPRESSES TUMOR GROWTH THROUGH CD8+T CELL MOBILIZATION AND ACTIVATION

YUE, S., FEI, L., XIN,Y.B.

SHANGHAI UNIVERSITY OF SPORT

INTRODUCTION: Aerobic exercise reduces the risk of cancer and disease recurrence. Yet the mechanisms behind this protection remain to be elucidated. The aim of this study was to investigate the anti-tumor effect and possible mechanism of regular treadmill running on MC38 colon cancer.

METHODS: Male C57BL/6 mice were placed placed in standard housing cages and maintained in a thermo-stated environment under a 12-hour light/dark cycle with free access to food and drinking water. At 8 weeks of age, mice were randomly divided into the exercise group (EXE, n=20) and the control group (CON, n=20). The EXE group mice were trained running using moderate intensity (60% of average maximum speed) for 60 min/day, 5 days/week for 4 weeks, and the control mice were housed with no intervention. After 4 weeks of aerobic running exercise intervention, the mice in both groups were inoculated with MC38 colon cancer cells, and the tumors were taken from each group when the average volume of the control mice reached 1000 mm3. Part of the tumor tissues were used for flow cytometry to detect the infiltration of immune cells (CD4+ T cells, CD8+ T cells, NK cells, macrophages, neutrophils). DAB staining of tumor tissues was used to further verify the infiltration of immune cells. Differential gene expression of tumor tissues was detected by RNA-sequencing; RT-PCR was used to verify sequencing results of differential genes in tumor tissues. Western Blot was used to detect the expression of key proteins of related signaling pathways and to clarify the possible mechanism pathways of aerobic exercise against tumor.

RESULTS: In mice inoculated with MC38 colon cancer cells, the tumor volume in the EXE group was significantly smaller than that in the CON group from day 8 after inoculation ($P < 0.01$). Flow cytometry results showed that the ratio of CD8+ T cells /tumor cells in tumor tissues of mice in the EXE group was significantly higher than that in the CON group ($P < 0.05$), while other immune cells did not show significant differences. Immunohistochemical results of tumor tissues showed positive CD8+ T cells consistent with the flow cytometry results ($P < 0.05$). RNA-SEQ results showed that the expression of inflammatory cytokines (Tgtp2, Zbp1, Gzmc, Gzmd) associated with interferon regulation and CD8+ T cell effector function were significantly higher in the tumors of the EXE group than in the CON group ($P < 0.01$). RT-PCR verified the results of RNA-SEQ ($P < 0.01$). Western Blot results showed that the phosphorylation levels of STAT and JAK proteins in tumor cells in the EXE group were significantly higher than those in the CON group ($P < 0.05$).

CONCLUSION: 4 weeks of moderate intensity treadmill running could exert an inhibitory effect on tumor growth of hyperimmunogenic MC38 colon cancer by increasing STAT and JAK protein phosphorylation levels and their mediated signaling pathways to induce CD8+ T cell mobilization and release of interferon-related inflammatory cytokines.

ASSOCIATIONS OF PHYSICAL FITNESS WITH NON-ALCOHOLIC FATTY LIVER RISK PARAMETERS IN BREAST CANCER SURVIVORS AND HEALTHY CONTROLS

KONG, I.

YONSEI UNIVERSITY WONJU COLLEGE OF MEDICINE

INTRODUCTION: Non-alcoholic fatty liver disease (NAFLD) is one of the most typical liver diseases globally. In middle-aged women, hormonal imbalance after menopause may result in an increased risk of NAFLD. In addition, breast cancer treatment is associated with an increased risk of NAFLD. However, there is a lack of clear evidence on the differences in NAFLD risk factors between breast cancer survivors (BCS) and healthy women is still lacking. Growing evidence has shown that a high level of cardiorespiratory fitness (CRF) may be associated with low risks of NAFLD or breast cancer. Also, muscular strength may be an important physical fitness marker given that sarcopenia is associated with both increased risks of NAFLD and breast cancer. However, the interrelationship of CRF and grip strength with NAFLD in BCS is unclear. Thus, the purpose of this study was to compare the NAFLD risk parameters between BCS and healthy controls (non-BCS), and to examine the association between NAFLD risk parameters and physical fitness levels.

METHODS: Using a case-control design, women with treated stage <4 breast cancer (n=40) and non-BCS women (n=40) were matched 1:1 by age and weight. We measured body composition using multi-frequency impedance technique (In-

Body 720, Biospace, Seoul, Korea), NAFLD risk parameters from blood samples (i.e., fasting glucose, insulin, ALT, AST, WISP-1, WISP-3, etc.), CRF using a step test, and grip strength using a handgrip dynamometer (TKK 5401, Japan). We also calculated Fatty Liver Index (FLI) which is a noninvasive method for predicting NAFLD. Descriptive statistics were used to compare characteristics. All study outcomes were compared using independent sample t-tests, or Mann-Whitney U-test, depending on the distribution of the data. Statistical significance was set at $p < 0.05$, and data were analyzed using SPSS version 20 (IBM Corp., Armonk, NY, USA).

RESULTS: Compared to non-BCS, BCS had significantly higher body fat percentages ($p<0.001$), fasting glucose ($p=0.02$), insulin ($p=0.04$), HOMA-IR ($p=0.02$), Aspartate transaminase (AST, $p<0.01$), and WNT1-inducible-signaling pathway protein (WISP-1, $p=0.01$). In contrast, WISP-3 ($p=0.02$), CRF ($p=0.02$), and relative hand grip strength ($p=0.01$) in BCS were significantly lower than in non-BCS. There was a significant relationship between fitness level and NAFLD risk parameters in both BCS and non-BCS. In particular, women with high CRF (BCS 20%, non-BCS 0%) had a significantly lower rate of FLI≥ 30 than women with low CRF (BCS 57.9%, non-BCS 44.4%).

CONCLUSION: BCS has a higher risk than non-BCS of developing NAFLD risk factors. To reduce the risk of NAFLD, it may be crucial to manage high levels of fitness.

EFFECTS OF A CLINICAL EXERCISE PROGRAM ON HEALTH-RELATED FITNESS AND QUALITY OF LIFE IN SPANISH CANCER PATIENTS RECEIVING ADJUVANT THERAPY

CARRASCO-CARRETERO, A., GIL HERRERO, L.

SPANISH CANCER ASSOCIATION

INTRODUCTION: Chemotherapy and radiotherapy are 2 widely used therapeutic approaches for the treatment of cancer. Despite their survival benefits, chemotherapy and radiotherapy cause several side effects which interfere with the patients' functional capacity and quality of life (1). Among the most common side effects of these treatments are nausea, fatigue, diarrhea, neutropenia, muscle weakness, cardiotoxicity, and main side effects that are directly related to a worse prognosis of the disease and an increase in mortality from a variety of causes: reduced cardiovascular capacity and changes in body composition including loss of muscle mass and gain of fat mass. Related to cardiorespiratory fitness (CRF), it has been observed that cancer treatments reduce it up to 30%which is associated with a worse prognosis of the disease and an increase of mortality (2). Moreover, changes in CRF are associated with changes in quality of life (QOL) and fatigue. Since there are no established pharmacological treatments for these side effects, much attention has been paid to other strategies and therapies to reduce these comorbidities. More specifically, exercise has been shown to improve these outcomes in cancer patients receiving adjuvant treatments such as chemotherapy and radiation therapy thereby improving fatigue and QOL. The aim of the study was to report the feasibility and effectiveness of a newly developed clinical exercise program for improving maximal cardiorespiratory fitness in Spanish cancer patients receiving adjuvant chemotherapy or radiation.

METHODS: The study was conducted at the exercise Oncology Unit of the Spanish Cancer Association in Madrid and it was a single group implementation feasibility study using a pre-posttest design. Participants performed a 12-week, twice-weekly, supervised, multi-component exercise program during adjuvant therapy

RESULTS: We had 100 cancer patients referred to the clinical exercise program of which 85 (85%) initiated the exercise program and 76 (89%) completed the post-intervention fitness assessment. Exercise significantly improved VO2max by 4.8mL/kg/minutes ($P<.001$). Exercise also significantly improved chest strength ($P<.001$), leg strength ($P<.001$), lean body mass ($P<.001$), skeletal muscle mass ($P<.001$), fat mass ($P<.001$), % body fat ($P<.001$), quality of life ($P=.0017$), and fatigue ($P=.007$)

CONCLUSION: A 12- week, supervised, multi-component exercise program was effective for improving health-related fitness in Spanish cancer patients receiving adjuvant therapy. Our results show the benefits of incorporating clinical exercise programming into the supportive care of cancer patients receiving treatments.

ASSOCIATIONS BETWEEN DOSE-DEPENDENT RESPONSES OF CARDIORESPIRATORY FITNESS AND BREAST CANCER MORTALITY: A SYSTEMIC REVIEW AND META-ANALYSIS

LEE, J., PARK, H., SUK, M., KANG, S.J.

KYUNG HEE UNIVERSITY - GLOBAL CAMPUS

INTRODUCTION: Conflicting findings about the associations between cardiorespiratory fitness and breast cancer are present in the literature. As such, this meta-analysis sought to investigate the associations between cardiorespiratory fitness and breast cancer mortality.

METHODS: Eleven studies were chosen for the current meta-analysis by searching the MEDLINE and EMBASE databases for English-language publications indexed between January 1990 and January 2023. Studies were deemed relevant for inclusion if they reported a relative ratio (RR) or hazard ratio (HR) of the associations between cardiorespiratory fitness and

breast cancer mortality, cancer mortality, and all-cause mortality. For inclusion, studies were required to indicate the methods of measuring cardiorespiratory fitness and report relative ratios (RRs) with 95% confidence intervals (CIs) or hazard ratios (HRs) with CIs of breast cancer mortality, cancer mortality, or all-cause mortality. Pilot, protocol, or review studies and studies that did not report RRs were excluded. A comprehensive meta-analysis version 1.25 software program (Biostatic, Inc., Englewood, NJ, USA) was used for this meta-analysis.

RESULTS: The cardiorespiratory fitness of breast cancer survivors was divided into three levels of low, moderate, and high to determine the associations between level of cardiorespiratory fitness and survival statistics, including breast cancer mortality, cancer mortality, and all-cause mortality.

CONCLUSION: High and moderate levels of cardiorespiratory fitness were inversely associated with breast cancer mortality, cancer mortality, and all-cause mortality compared to low cardiorespiratory fitness. Additionally, increased 1-MET of cardiorespiratory fitness was associated with cancer mortality and all-cause mortality, but an association between cardiorespiratory fitness and breast cancer mortality was not found because of a lack of appropriate studies to compute the summary of RRs. In summary, breast cancer mortality, cancer mortality, and all-cause mortality depend on the level of cardiorespiratory fitness, and cardiorespiratory fitness plays a pivotal role in cancer survival, including surviving breast cancer survival, other cancers, and other associated diseases.

Increased cardiorespiratory exercise can help to enhance breast cancer survival, cancer survival, and all-cause survival. The preferred level of cardiorespiratory fitness was more than 7 METs, but more studies to support this are needed. Enhancing 1-MET cardiorespiratory fitness decreased cancer mortality and all-cause mortality. No association between increased 1-MET cardiorespiratory fitness and breast cancer mortality was found due to a lack of relevant studies. Further research to find the association between cardiorespiratory fitness and breast cancer survival may be needed.

EFFECTS OF PERIOPERATIVE EXERCISE THERAPY ON CARDIORESPIRATORY FITNESS, POST-OPERATIVE COMPLICATIONS AND 5-YEAR SURVIVAL RATE IN PATIENTS WITH COLORECTAL CANCER: A SYSTEMATIC REVIEW AND META-ANALYSIS

HENNESSY, D., MILLER, K., KHAN, N., MARIN EDO, S., AREEROB, P., WALLEN, M., GRACE, F.

FEDERATION UNIVERSITY AND DEAKIN UNIVERSITY

INTRODUCTION: Exercise has demonstrated to be beneficial for cancer patients in improving physical fitness [1]. Furthermore, improving cardio-respiratory fitness before and after surgery has potential to improve important post-operative outcomes [1,2]. Therefore, this systematic review and meta-analysis evaluated the effects of perioperative exercise therapy (aerobic, resistance, mind-body, flexibility, or mixed exercise (combined aerobic and resistance)) on cardio-respiratory fitness, post-operative complications and 5-year survival rate for patients diagnosed with colorectal cancer undergoing surgery.

METHODS: All methodological processes for this meta-analysis (i.e., data extraction, collection and analysis) and reporting were conducted in accordance with the Preferred Reporting Items for Systematic review and Meta-Analyses (PRISMA) guidelines. Eligible published randomised controlled trials were identified from an electronic database search (inception - 31st May 2020). Databases included PubMed, CINAHL, SPORTDiscus, Cochrane Library (CENTRAL), and Web of Science.

RESULTS: The systematic electronic search resulted in a total of 1,849 individual records. Researchers found 18 eligible trials (401 patients) that were subsequently included in the analysis. Pooled standardised mean differences (SMD) with 95% confidence intervals (CI) were compared and heterogeneity assessed using Cochran's Q and I2 statistics. Exercise either before or after surgery showed a small improvement in cardio-respiratory fitness (SMD = 0.18, 95% CI = 0.03, 0.32; $p < 0.05$). Exercise was also shown to improve anaerobic threshold (AT) in colorectal, colon and rectal cancer patients when compared to usual care (SMD = 0.53, 95% CI = 0.11; $p < 0.05$). Additionally, post-operative complications (Clavien-Dindo classification) and adverse events were found to have no significant differences.

CONCLUSION: These results demonstrate that perioperative exercise (whether alone or in combination) has the potential to safely improve cardio-respiratory fitness in colon, rectal and colorectal cancer patients. Therefore, primary care and allied health practitioners should consider the benefit of perioperative exercise therapy as a complementary component to standard colorectal cancer treatment.

EFFECT OF EXERCISE-CONDITIONED SERA FROM CHILDREN WITH CANCER ON THE PROLIFERATION OF EWING SARCOMA AND RHABDOMYOSARCOMA CELLS

RIST, S., HALLER, B., SCHÖNFELDER, M., KASTENMÜLLER, G., WACKERHAGE, H., VON LUETTICHAU, I.

TECHNISCHE UNIVERSITÄT MÜNCHEN

INTRODUCTION: Exercise not only improves the fitness and well-being of adult cancer patients, but it also has direct effects on cancer itself including effects on cancer cell proliferation. Childhood cancers differ from adult cancers, and it is

poorly understood whether exercise affects cancer hallmarks in pediatric cancer patients. The aim of this study was therefore to 1) investigate whether incubation of two sarcoma cell lines with exercise-conditioned sera alters cell proliferation compared to resting sera and 2) whether there are metabolite biomarkers whose concentration predicts the proliferative/mitotic effect of a serum.

METHODS: We screened 212 patients with pediatric malignancies of which 11 children performed a high intensity interval training (HIIT) with 10 x 15 s intervals (1). Blood was drawn before and after the exercise and processed to serum. Subsequently, we incubated Ewing sarcoma (A673) and rhabdomyosarcoma (RD) cells with 10% exercise-conditioned or control media in triplicates and measured cell proliferation by WST-1 assay. Proliferation data were further correlated to serum metabolites quantified by mass spectrometry (AbsoluteIDQ p180 kit).

RESULTS: To find out whether exercise alters A673 and RD proliferation, we incubated these cells with the resting and exercise-conditioned sera and measured proliferation by WST-1 assay. When compared to sera taken at rest, exercise-conditioned sera reduced proliferation of A673 cells by 7 ± 30% (p=0.2), and of RD cells by 3 ± 7% (p=0.22), respectively. However, the inter-individual difference between proliferation responses to patient sera was greater: up to 400% for the A673 cell line and 84% for the RD cell line.

Next, to identify possible metabolite biomarkers for proliferation, we correlated exercise-induced metabolite concentration changes with exercise-induced proliferation changes.

This revealed two metabolite concentration ratios: Ornithine (Orn) to Arginine (Arg) (RD cells: r=0.788, p=0.006; A673 cells: r=0.782, p=0.006) and Asymmetric Dimethylarginine (ADMA) to Arg (RD cells: r=0.910, p=0.0002; A673 cells: r= 0.622, p=0.045).

CONCLUSION: The main finding of this study is that exercise-conditioned sera decreased the proliferation of Ewing sarcoma and rhabdomyosarcoma cells by less than 10%. However, we found large inter-individual variations in the proliferation effect of sera from different patients. Moreover, the serum changes of the ADMA/Arg and Orn/Arg ratios in response to exercise correlate with the change of proliferation in sarcoma cells, identifying ADMA/Arg and Orn/Arg ratios as candidate biomarkers for the proliferation effect of sera.

CP-BM06 Balance and Coordination

CORTICOSPINAL EXCITABILITY CHANGES AND MODULATION INDUCED BY SHORT-TERM BALANCE PERTURBATION TRAINING

HU, N., WALKER, S., PIIRAINEN, J.M., AVELA, J.

UNIVERSITY OF JYVÄSKYLÄ-FI02458947

INTRODUCTION: Balance control is a fundamental motor skill that requires rapid adaptation to dynamically changing environments (i.e. balance perturbation tasks). Several studies have examined how sensorimotor training (1), strength training (2), and even cognitive training (3) can improve balance control and induce neural modulation during training. However, neural modulation is known to be highly related to the motor task. Currently, little is known about how repeated balance perturbation training affects balance performance and its neural control. Therefore, this study investigated corticospinal adaption and its modulation in short-term balance perturbation training.

METHODS: 12 subjects completed two test sessions (TS1 and TS2) and one identical perturbation training session in between. The balance perturbation system operated at 25cm/s, accelerating at 2.5m/s2 over 30cm displacement in anterior or posterior directions, randomly. During the training session, subjects under 200 perturbations. In each test session, single-pulse TMS at 110% active motor threshold and electrical stimulation at 5% (±2%) of maximum M-wave elicited motor evoked potentials (MEP) and H-reflexes in the right leg soleus muscle, respectively, at two delays (40ms: short latency response (SLR) and 140ms: voluntary activation) after the onset of perturbation. Average velocity of center of pressure (COP) (mm/s) and maximum displacement (mm) was analyzed 1s before perturbation (Pre- phase), during perturbation (Act-phase) and 1s after perturbation (Rec-phase), respectively, normalized by individual height and body weight (m*kg).

RESULTS: COP velocity decreased at all the three phases in TS2 when compared to TS1 by Paired t-test (Pre-phase, TS1:0.148, TS2:0.121 ((mm/s)/(m*kg)), p = 0.024; Act-phase, TS1:1.726 , TS2:1.384 ((mm/s)/(m*kg)), p = 0.006; Rec-phase, TS1: 1.037, TS2: 0.719 ((mm/s)/(m*kg)), p<0.001). MEP/H-reflex ratio demonstrated significant decreases at voluntary activation phase (140ms) after perturbation training (TS1: 0.44 ± 0.33, TS2: 0.29 ± 0.14, p = 0.026). No differences occurred at SLR phase (40ms).

CONCLUSION: The main hypothesis of this study was that balance performance would improve together with a reduction in cortical excitability after short-term balance perturbation training. This hypothesis was supported by the finding of a progressively reduced velocity of COP in TS2. However, MEPs which represents corticospinal excitability did not change. On the other hand, the MEP/H-reflex ratio showed a reduction during the voluntary activation phase in TS2. This implies that neural control may have been transferred from motor cortex to more sub-cortical structures. This is in-line with a

previous study, in which acquired motor knowledge was stored in the sub-cortical area (i.e., basal ganglia) and can be recalled via cortical to sub-cortical network connections (4).

EFFECTS OF INDIVIDUALIZED THERAPY ON OBJECTIVE AND SUBJECTIVE INSTABILITY AFTER ANKLE INVERSION TRAUMA

JANAUSCHEK, S., FENNEN, L., MILSTREY, A., OCHMANN, S., DUBBELDAM, R.

WESTFÄLISCHE WILHELMS-UNIVERSITÄT MÜNSTER

INTRODUCTION: In chronic and acute ankle instability, postural control has been quantified using the amount and structure of variability of the centre of pressure (CoP) [1,2,3]. This study aims to analyse the objective and subjective recovery of postural control of acute and chronic patients during their rehabilitation process and compare them to healthy controls.

METHODS: Sixteen patients (26 ± 6 years) suffering from ankle instability after ankle inversion trauma were evaluated over 3 months. The patients received individual physiotherapy focusing on e.g., muscle strengthening, coordination, and or joint mobility. One-limb stance eyes-open and eyes-closed performance was recorded for 60 seconds using Qualisys 3D motion analysis system. Performance was quantified by assessing CoP cumulative distance, standard deviation, and sample entropy as percentages of the healthy control means. The FAAM and CAIT were used to monitor daily life performance subjectively. Objective and subjective performance assessments were made in weeks 0, 3, 6 and 12. Mixed models allowing for subject differences were used to test for effects.

RESULTS: There was no significant difference between chronic (6) and acute (10) patients. At week 0, standard deviation and cumulative distance were 10-16% and 10-30% higher, respectively, in patients compared to controls. Sample entropy was 3-12% higher with eyes-open and 2-8% lower with eyes-closed in patients compared to controls. This difference reduced significantly for all parameters by 0.7-1.4% per week. Also, the patients reported a significant improvement in daily activities (FAAM-ADL), sports (FAAM-S), and instability score (CAIT) over time.

CONCLUSION: In both one-limb stance conditions, the patients showed larger excursions than the healthy controls. Furthermore, with eyes open, the patients showed noisier postural control while in the eyes-closed situation, the patients showed more rigid control. The differences between the patient and healthy groups converge over time, which was accompanied by a subjective reduction of instability impairments.

COMPARISON OF RESULTS OF SCALING ANALYSIS OF FORCE PLATFORM AND EMG RECORDS OF STANDING WITH KNEE INJURY

RADIC, I.1, BLESIC, S.1, STEFANOVIC, Z.2, MIRKOV, D.2, KNEZEVIC, O.2

1. INSITUT FOR MEDICAL RESEARCH 2.FACULTY OF SPORT AND PHYSICAL EDUACTION

INTRODUCTION: We compared long-range temporal characteristics of simultaneous force platform and EMG records of quiet standing with knee injury to one leg only, with same sets of data from non-injured standing. The EMG data in our dataset were taken from m. quadriceps femoris of both (injured and non-injured) legs. We analysed all our recordings from two force platforms, to assess scaling in quiet standing for each leg separately.

METHODS: We used wavelet transform spectral analysis (WTS) to quantify force platform and EMG data, to characterize quite standing with WTS peaks as relevant parameters, and to show how those parameters change with knee injury to one leg. WTS is a method comparable to Fourier spectrum analysis (PwS) that has better signal localization in both time and scale (frequency). It is a two-dimensional time series decomposition in both time and frequency, with functions constructed by expanding by time scale and translating along real time of a specifically chosen original wavelet function.

RESULTS: We found long-range autocorrelated behaviour in all our force platform records, with a visible crossover in long-range dynamics, a random behaviour on small time scales and a distinct non-linearity on higher time scales. Under the knee injury to one leg, only the scaling above the crossover, on time scales from 100ms to 1s, changed in our dataset. We observed two main types of response to injury: a compensation, seen as an increase of all the characteristic modes above the crossover point that causes a shift of the position of crossover to smaller scales, and an 'underachievement', which presents as a decrease of amplitudes of the characteristic WTS peaks above the crossover region that brings about a shift of the position of crossover point to higher time scales. We found that, especially for the 'underachievement' behaviour, changes in WTS spectra associated with the knee injury are mainly visible in changes of the amplitude of WTS peaks

at 250ms and 650ms. Our EMG WTS results provided further insights into the m. quadriceps femoris engagement and engagement time scales (frequencies) that are associated with this change.

CONCLUSION: Our results show that scaling techniques such as WTS can distinguish knee injury even in quiet standing. In that regard, those can be used as simpler and less invasive methods to detect or understand injury.

INTER-JOINT COORDINATION DURING UNILATERAL SEATED SHOT PUT TEST

BLACHE, Y., DEGOT, M., MARTIN, E., ROGOWSKI, I.

UNIVERSITÉ LYON 1

INTRODUCTION: The Unilateral Seated Shot-Put Test (USSPT) as described by Chmielewski et al. (1) consists of a maximal forward push of a 3-kg medicine-ball from a seated position. Distance reached is positively correlated to maximal upper-limb pushing power and is about 8% superior for the dominant side in comparison to the non-dominant one (2). Nevertheless, such a side difference is not explained by bilateral maximal power difference, suggesting that other factors like inter-joint coordination may be involved. The purpose of this study was therefore to assess the influence of upper-extremity side on inter-joint coordination during USSPT.

METHODS: Fifteen healthy male athletes (Age: 24.4±2.8 years; Height: 179.1±7.6 cm; Mass: 72.0±7.9 kg) were involved in this study. After being fitted with 56 reflective markers located on the trunk, clavicle, scapula, humerus, forearm and hand, they performed one familiarization trial followed by three USSPT trials per side. Raw marker trajectories were recorded with a 10-cameras optoelectronic system. Humerothoracic, elbow and wrist angles were computed for each side using a multibody kinematic optimization, and derived by the time to obtained angular velocities. Percentages of movement corresponding to peak angular velocity of humerothoracic flexion, elbow extension and wrist flexion were kept for analysis. USSPT distances were allometrically normalized.

RESULTS: USSPT distances were significantly higher for the dominant side in comparison with the non-dominant one (86.9±9.3 cm.kg0.35 vs 83.1±5.9 cm.kg0.35, $p<0.05$). For the dominant side, humerothoracic peak velocity was achieved before ($p<0.05$) elbow peak velocity, which was achieved before ($p<0.01$) wrist peak velocity (71.3±19.0% vs 86.0±3.9% vs 90.4±3.1%, respectively). For the non-dominant side, humerothoracic peak velocity was achieved before ($p<0.05$) elbow and wrist peak velocities, while the two latter occurred simultaneously ($p=0.13$) (69.3±18.1% vs 85.9±4.4% vs 87.8±7.4%, respectively).

CONCLUSION: Similarly to ballistics movements (3), upper-extremity inter-joint coordination during USSPT is characterized by a proximo-distal sequence. Nevertheless, the alteration in this sequential coordination for the non-dominant side may explain the lower USSPT distance reached in comparison to the dominant side. Our findings provide a first evidence of inter-joint coordination involvement in the USSPT performance.

JOINT MOVEMENT PHASE DIFFERENCES DURING SITTING DOWN AND STANDING UP MOVEMENTS BETWEEN PEOPLE WITH AND WITHOUT LOW BACK PAIN

SUTANTO, D.

THE CHINESE UNIVERSITY OF HONG KONG

INTRODUCTION: Past kinematic studies compared the joint movement of people with and without Chronic Low Back Pain (CLBP) during sitting down and standing up tasks. Different studies tend to use slightly different tasks and different data analysis methods, causing difficulty in results synthesis in a meta-analysis. Five Repetition Sit-To-Stand (5RSTS) test are validated and objective physical functioning tests where people with and without CLBP have significant performance differences, and were used as the measured tasks in this study to investigate significant difference in trunk and lower limb joint movement kinematics.

METHODS: 34 Men and women aged 19 to 55 with CLBP and minimum Oswestry Disability Index (ODI) score of 16 were recruited and compared to 20 asymptomatic participants. Both CLBP and asymptomatic participants had reflective markers attached to their trunk and lower limbs and were instructed to do the 5RSTS test with joint position data captured using 11 Vicon motion capture cameras . Maximal joint Range of Motion (ROM), Mean Absolute Relative Phase-angle (MARP) and Deviation Phase were calculated for each participant. One-way Multivariate Analysis of Covariance (MANCOVA) with CLBP status as the independent variable and gender, age and height as the covariates to investigate the difference between groups.

RESULTS: CLBP participants have significantly larger left knee to left hip and right knee to right hip MARP and DP on the standing up movement, with $F(24,26) = 1.944$, $p = 0.05$, Wilks' $\Lambda = 0.358$, and partial $\eta 2 = 0.642$ in 5RSTS task. CLBP status did not have significant effects on the maximal joint ROM in the analysis.

CONCLUSION: CLBP participants' lower limb joint coordination was significantly out-of-phase, with a larger standard deviation compared to asymptomatic participants, with no significant difference in maximal joint ROM during sitting down and standing up from a chair. This result indicates that despite significantly lower speed performance in CLBP participants, they do not have significant joint movement restrictions to fulfill the 5RSTS tast. Future intervention studies may consider focusing on trunk and lower limb joint movement coordination on people with CLBP instead of increasing their maximal range of motion.

ADAPTIVE FORCE – THE CONCEPT, MEASUREMENT AND POTENTIAL IMPORTANCE OF A NEUROMUSCULAR FUNCTION

BITTMANN, F.N., DECH, S., SCHAEFER, L.V.
UNIVERSITY OF POTSDAM

INTRODUCTION: Orthopaedic injuries are related to muscle lengthening actions under load.[1] During motion the neuromuscular system often has to adapt to external forces by adjusting the muscle tension and length permanently to the varying external circumstances. For this neuromuscular function, the term Adaptive Force (AF) was introduced.[2,3] For AF assessment the subject has to adapt adequately to an increasing external force while holding isometrically. If the maximal holding force (AFisomax) is exceeded the muscle starts to lengthen. The external load should be decelerated further as good as possible (peak value = AFmax). Holding isometric and eccentric muscle actions require high efforts of motor control,[2-5] especially during adaptation to changing external demands. It was shown that afferent influences, as imagery,[6,7] odors,[3] and post-infectious states (Long COVID) [8,9] can affect the holding capacity. However, this neuromuscular function was not considered in motor science so far. The aim is to objectify the AF, present its neurophysiological particularities and to discuss its possible value.

METHODS: To measure AF, force and kinematics have to be monitored simultaneously while a subject adapts to a varying external load, firstly isometrically. Two devices were developed to objectify the AF: (1) pneumatic system (pneumatically controlled lever pushes against the subject); (2) handheld device (force increase is applied manually by an examiner via handheld device). The decisive parameter to be identified is the force at the moment in which the subject merges from holding isometric to eccentric action (AFisomax).

RESULTS: Both systems show force-angle courses in a reproducible way. Muscles of healthy subject start to lengthen at submaximal forces (~80% MVIC) when tested with the pneumatic device. During manual testing 100% of AFmax or MVIC can be reached and mutual oscillations (~10 Hz) appear. In case of disturbing stimuli AFisomax is significantly reduced (~50% of AFmax) but the force increases further during lengthening. AFmax and MVIC do not differ significantly. Moreover, AFmax does not react to disturbing stimuli as AFisomax does.

CONCLUSION: Early yielding muscles could imply instability of the related joint. It is suggested that a low AFisomax (related to AFmax or MVIC) reflects a reduced muscular stabilization. The holding capacity might indicate functional disturbances which could be relevant for different health conditions. Muscular instability couldcould be tied with risk of musculoskeletal complaints, and injury mechanisms.

ANKLE AND KNEE STABILITY AS PREDICTORS FOR DYNAMIC BALANCE

BERNHARDT, V., OLDHAM, M.D.
TEXAS A&M UNIVERSITY-COMMERCE

INTRODUCTION: The Y-balance test (YBT) is a commonly used clinical tool to predict lower extremity injury risk in athletic populations. Specifically, anterior and posteromedial reach asymmetries of ≥4 cm have been found to elevate injury risk [1,2]. It is unclear which factors impact YBT dynamic balance. In this study we examined whether muscle mass difference between lower limbs, joint movement during unilateral squat, or static balance during stork balance test were associated with YBT dynamic balance performance.

METHODS: 14 collegiate Division 1 female volleyball players (20.4 ± 1.8 yrs, 174.9 ± 7.6 cm, 69.7 ± 9.3 kg) completed body composition scan via dual x-ray absorptiometry, dynamic balance testing via YBT, and movement analysis via 3-D markerless DARI Motion. YBT reach distances were performed in three directions: anterior, posteromedial, and posterolateral; and difference between left and right legs was calculated. For the unilateral squat, participants were asked to stand on one leg with arms outstretched in front, then squat as low as possible. Sway during a 30-sec open-eyes stork test on either leg was calculated. All assessments were conducted during one visit shortly after the team's competition season. Data were analyzed using Pearson correlation and stepwise linear regression.

RESULTS: Average reach differences were 6.4 ± 7.1 cm for anterior, 4.4 ± 2.9 cm for posteromedial, and 3.8 ± 3.4 cm for posterolateral. Lean mass was similar in the legs (left: 7740 ± 1301 g or 62.6 ± 3.0%, right: 8070 ± 1407 g or 63.2 ± 3.2%). No significant correlations were found between YBT reach differences and leg lean mass differences ($p > 0.05$). Posterolateral reach difference was correlated with dynamic knee valgus (left knee $r = 0.56$ and $p = 0.046$, right knee $r = 0.56$ and $p = 0.048$) and ankle flexion ($r = 0.55$, $p = 0.051$) during the unilateral squat. No other correlations with joint angles were found. Right and left ankle medial/lateral sway during stork balance test significantly predicted anterior reach difference ($r2 = 0.75$, $p = 0.001$).

CONCLUSION: Lower limb muscle mass was not associated with dynamic balance. Ankle and knee stability seem to play a role in maintaining dynamic balance. Strength and conditioning programs should focus on ankle and knee functional dynamics.

SMART EYEGLASSES TO CHARACTERIZE PHYSICAL PERFORMANCE OF OLDER ADULTS: A CLUSTERING-BASED APPROACH ON FUNCTIONAL AND BIOMECHANICAL PARAMETERS

COLSON, S.S., HELLEC, J., JAAFAR, A., GUÉRIN, O., CHORIN, F.

UNIVERSITÉ CÔTE DAZUR

INTRODUCTION: The decline in physical capacities with aging is often associated with falls and/or frailty. Falls and/or frailty are detrimental for older adults, impairing their quality of life and leading to a progressive loss of autonomy. Assessing falls and/or frailty with multifactorial measures is highly recommended due to the complexity and non-linearity that characterizes older adults' clinical status [Lee et al., PM&R, 2013]. For this purpose, recent approaches using unsupervised analyses helped to categorize the risk of falling from different clinical tests [Wong et al., IEEE, 2021]. In addition, the development of wearable technologies integrated in everyday objects allows the monitoring of daily life movements. The purpose of this study was to characterize a population of older adults through the measurement of functional and biomechanical parameters collected with an accelerometer embedded in smart eyeglasses.

METHODS: Eighty-four older adults equipped with connected smart eyeglasses performed different functional tests (i.e., 30-s Sit-to-Stand, 6-min walk and Timed-Up and Go [TUG] in comfort and fast condition). Seven functional and biomechanical parameters (i.e., number of Sit-to-Stand, maximal vertical acceleration values during Sit-to-Stand movements, total walking distance, step duration and length, duration of TUG in both conditions) were collected from the smart eyeglasses' acceleration data. First, supervised analyses (ANOVAs) compared the parameters measured between groups according to their "fall" and "frailty" status. Second, an unsupervised analysis (i.e., clustering algorithm based on K-means) was realized to characterize the participants from the functional and biomechanical parameters.

RESULTS: Only one of the seven parameters (i.e., step length) tended to differ according to "fall" status ($p=0.06$). While no parameters differed between frail and pre-frail participants, five of them were different ($p<0.05$) between frail and robust participants (i.e., number and maximal vertical acceleration of Sit-to-Stand, distance covered, step length, TUG time in fast condition). The unsupervised analysis characterized the population into three distinct physical performance groups (i.e., low, intermediate, and high). The seven parameters measured were useful to differentiate the low and high-performance groups. Four of the measured parameters (i.e., distance covered, step length, TUG time in both conditions) discriminated the three performance groups ($p<0.05$). In addition, the low-performance group had a higher proportion of frail participants ($p<0.01$).

CONCLUSION: The seven functional and biomechanical parameters were different between the physical performance groups determined with the unsupervised analysis. An accelerometer embedded in smart eyeglasses, an object of everyday life for most of older adults, could be useful to assess daily life movements and to identify a possible decline and/or improvement of physical capacities.

THE TRUNK'S CONTRIBUTION TO POSTURAL CONTROL FOR CHILDREN WITH CEREBRAL PALSY.

DUCHENE, Y.1, PIERRET, J.2, BEYAERT, C.1,2, CAUDRON, S.3

1 UNIVERSITÉ DE LORRAINE, CARE GRAND EST - DEVAH, NANCY, FRANCE ; 2 INSTITUT RÉGIONAL DE RÉADAPTATION, UGECAM NORD-EST, NANCY, FRANCE ; 3 UNIVERSITÉ DE GRENOBLE ALPES, CNRS, LPNC, GRENOBLE, FRANCE

INTRODUCTION: In typically developing (TD) children, postural sway control matures from infancy through adolescence[1]. The individual contribution of each joint to postural oscillations in orthostatic posture has not been questioned in pediatric population. In particular, while the inverted double pendulum model is widely accepted, it is now suggested that the involvement of the upper body, and especially the trunk, should also be considered[2]. Trunk control, which is a determining factor in the acquisition of posturokinetic abilities[3], is also known to be deficient in children with cerebral palsy (CP)[4], which could impact their oscillation control strategies. Therefore, the aim of this study was to determine the relative contribution of the trunk to the lower limb joints in the control of postural oscillations in TD and CP children.

METHODS: Seventeen TD children and 13 PC children aged 7 performed one quiet stance task. They had to stand as still as possible during 20 seconds, on two force plates (AMTI, Watertown, MA, USA). Whole-body kinematics were measured using 3D motion capture with 9 cameras (Vicon, Oxford Metrics, Oxford; UK) with the Conventional-Gait-Model markerset. Kinetics and kinematics were sampled at 1000Hz and 100Hz respectively. The ankle, knee, hip and trunk range of motion (Amp), angular velocity (Vel) and standard deviation (SD) in the sagittal plane were computed. We also calculated the Amp, Vel and SD from the anterior-posterior center of forces (CoF) data. We performed multiple linear regression analyses

of joint kinematic variables as predictors of the CoF matching variables, for our two populations. The threshold for statistical significance was set to $p<0.05$.

RESULTS: The Amp-model was significant ($R^2=0.67$), with the ankle having the greater B-coefficient absolute value (B=2.05), followed by the trunk (B=0.58), the knee (B=-0.37) and the hip (B=-0.12) for the TD children group. The SD-model and the Vel-Model were not significant.

With the CP children, the Amp-model and SD-model were significant ($R^2=0.78$ and $R^2=0.71$ respectively), with absolute values of B-coefficients higher for the ankle (B=-3.53 and B=-3.03) than for the knee (B=1.86 and B=1.43), the trunk (B=1.09 and B=0.88) and the hip (B=-0.47 and B=-0.23). The Vel-Model was not significant ($R^2=0.38$, $p=0.38$).

CONCLUSION: In both groups, the trunk was more important than the hip in controlling balance, underlining that the double inverted pendulum model blurs the real impact of the trunk[2]. Trunk control disorders have been shown to be a significant predictor of lower limb behavior during walking in CP children, more than neuromuscular dysfunction[5]. Because of this, it is possible that the larger contribution of the ankles and knees in PC children are compensatory strategies for poor trunk control, which is known to influence postural sway during sitting and standing[4].

RELIABILITY AND VALIDITY OF AN INERTIAL SENSOR-BASED KNEE ANGLE MEASURING DEVICE FOR GAIT SONIFICATION

LINNHOFF, D., PLOIGT, R., MATTES, K.

UNIVERSITÄT HAMBURG

INTRODUCTION: For real-time feedback devices in gait therapy, accurate measurement of the corresponding gait parameter is important. Additionally, the technique should be cost-effective and simple in application to make it accessible to patients. Inertial sensor-based systems are comparably low in cost, while still having good measurement agreement for relevant gait parameters (Petraglia et al., 2019; Picerno et al., 2017). The aim of this study was to test the measurement capability of a self-developed IMU-based gait sonification system (sofigait, BeSB, Berlin, Germany) that measures and sonifys the sagittal knee angle curve in real-time.

METHODS: The study was carried out with a sample of N=28 participants (22.8 ± 2.9 years) on a treadmill (cosmos hp). It consisted of determining the criterion validity of the knee angle measurement by comparison of the measurement with an optical system (Vicon, Oxford, UK). Prior to this, testing for temporal stability and for reproducibility of the knee angle measurement was conducted with two persons (34 ± 2 years, 172 cm). Each person did 5 trial walks for 5 continuous minutes.

RESULTS: For the first part, deviations were calculated for four events of the curve (2 maxima, 2 minima). Within each 5-minute walk, deviations ranged from 0.36° to 8.21° for all events with a mean of 2.23° ± 1.5°. Between the different walks (reproducibility), measurements deviated in a range of 0.9° to 12.09° (mean 5.41°). For the measurement comparison, the root mean squared error (RMSE) was 7.6° ± 2.6° (left) and 6.9° ± 3.1° (right). Statistical parametric mapping (SPM) revealed significant differences between the two measurement systems for the range 45 - 90% of the gait cycle ($p < .001$) (left) and 45 - 80% ($p = .007$) (right).

CONCLUSION: No systematic drift over time was detected and the variation between the repeated measurements was greatest for the peak angle values. In terms of criterion validity, differences between the optical motion-capturing system and the prototype inertial-sensor-based system were found to be in the expected range. The RMSEs are comparable to Favre et al. (2009). The SPM further revealed non-agreement between both systems in the area of maximum knee flexion.

It is concluded that the knee angle curve is reliably reproduced by the inertial sensor system for the purpose of generating sonification feedback.

A QUALITATIVE CASE STUDY ON EXPERTISE OF SPRINT GUIDE RUNNER : CONSIDERATION BASED ON CASE OF FOUR ATHLETES WITH SEVERE VISUAL IMPAIRMENT FOR OVER 20 YEARS.

KONDO, K.1, MORIOKA, Y.1, OGATA, M.2

1 NIHON UNIVERSITY, 2 UNIVERSITY OF TSUKUBA

Introduction

The guide discussed in this study is a specific method for the competitions with visually impaired athletes in Paralympics, in which the guides directly assist athletes to run by holding a guide rope with the athlete, so as to ensure their smooth participation of the competitions. Athletes who require a guide runner are with severe visual impairments. It is indispensable for them to have direct support such as guide runners to run in competitions. However, securing guide runners is still recognized as a challenging issue, especially for short-distance (sprint) events. It is considered that clarifying the factors necessary to be sprint guide runners and presenting role models would be effective to secure sprint guide runners. The purpose of this study was to qualitatively examine the factors related to the development of expertise in a sprint guide runner.

Methods

The subject was one adult male who had experiences as a sprint guide runner for various severe visual impaired athletes for about 20 years. He was asked to cooperate and give consent based on the common purpose viewpoint in qualitative research. In this study, the analysis was conducted using a method based on semi-standardized interviews and the structure laying techniques (Flick, 2011 ; Japanese edition) to reconstruct the subjects subjective theory.

Results

As a result, the subject had no prior knowledge of sprint guide runner and had never had any contact with visually impaired people. The subject started the guide activities by working and learning from a visually impaired person who became his first partner. The subject is now taking actions to maintain appropriate distance in daily life and trying to establish a "normal" relationship considering "gender," "age," and "whether the disability is congenital" to build a good relationship. It has been revealed that the process of creating synchronized movements using the guide rope as "sensor" is important in sprint guiding methods. The study also indicated that guiding a sprint runner requires quick movements and also split-second timing to judge while running which are still difficult to control. In addition, when his partner was a junior athlete who was considerably slower and had a height difference, it was necessary for the subject to lower the position of the guide rope and adjust to "slower pace" of the partner.

Discussion

Compared to long-distance running, sprint guide runners must start using starting blocks. In some cases, they may also need to serve as a "caller" in the long jump event. Becoming proficient sprint guide runner may take time, but it will increase the potential for training up sprint guide runners for athletes with sever visual impairments through the learning programmes taken into consideration the cases and factors shown by this study.
