Introduction

The Milky Way (our Galaxy) is a huge system that consists of 100–400 billion stars, interstellar gas, interstellar dust, cosmic rays, electromagnetic radiation, interstellar magnetic field, gravitational field, dark matter particles. In spiral galaxy like the Milky Way, most of the dust and gas is found within relatively thin disk with a thickness of a few hundred pc and within this disk nearly all of the star formation takes place.

Among the least investigated directions in the Milky Way are dark clouds in the Camelopardalis constellation. The distances to these clouds and interstellar extinction are known with a low accuracy and only in some occasional directions (Zdanavičius et al. 2001).

A few years ago Straižys & Laugalyš (2007a, 2008) described a ring-like concentration of dust clouds located at the border of the Perseus, Camelopardalis, and Auriga constellations, which is perfectly seen in the Dobashi et al. (2005) atlas of dark clouds (Fig 0.1).

This ring includes the following Tokyo clouds: 942 (P7, P8), 994, 1003, 1036, 1041, 1027, 1014, 1006, 989 and contains 10 Cam OB1 association members, some young variable stars and H α emission stars. The ring has a diameter of $\sim 8^\circ$ and is centred on the open cluster NGC 1528. Trying to test physical reality of this dust ring, we decided to investigate distances to its clouds and their extinction properties in three selected dust ring areas (1.5 square degree each). The method of investigation is based on photometry of stars in the Vilnius seven-colour system, determination of their spectral and luminosity classes, reddening, extinction and distances.

A curved $\sim 5^\circ$ -long chain of dark clouds, located westwards from the quadruple star 1 Cam (DL Cam, HD 28446), was described in the Barnard (1927) catalogue and atlas of dark clouds (clouds B8, B9, B11, B12). Barnard writes that this chain of dark clouds breaks up into more or less separate spots, “somewhat resembling those at the east end of the great lane from Rho Ophiuchi”. Again, dust clumps of this chain appear in the catalogues of dark clouds by Lynds (1962), Taylor et al. (1987), Dutra & Bica (2002), Dobashi et al. (2005), and Dobashi (2011). Unfortunately, it is not easy to cross-identify separate clouds in different catalogues since their boundaries usually remain undefined. The present investigation covers the clump P1 of the cloud TGU H994 (Dobashi et al. 2005), which includes the Barnard cloud B11 and the Lynds clouds LDN 1399, LDN 1400, and LDN 1402.

Until now these clouds were investigated in the molecular bands: CO (Dickman 1975; Snell 1981; Myers & Benson 1983; Taylor et al. 1987; Dame et al. 1987, 2001; Park et al. 2004; Wu et al. 2012), H₂CO (Dieter 1973; Minn & Greenberg 1973; Sandqvist et al. 1988; Clark 1991), NH₃ (Myers & Benson 1983; Benson & Myers 1989; Clark 1991), CS, and N₂H (Lee & Myers 1999). The local standard of rest (LSR) velocity of these clouds is 2–4 km/s. Myers & Benson (1983) identified a group of visually opaque gas and dust condensations in the cloud LDN 1400 and the

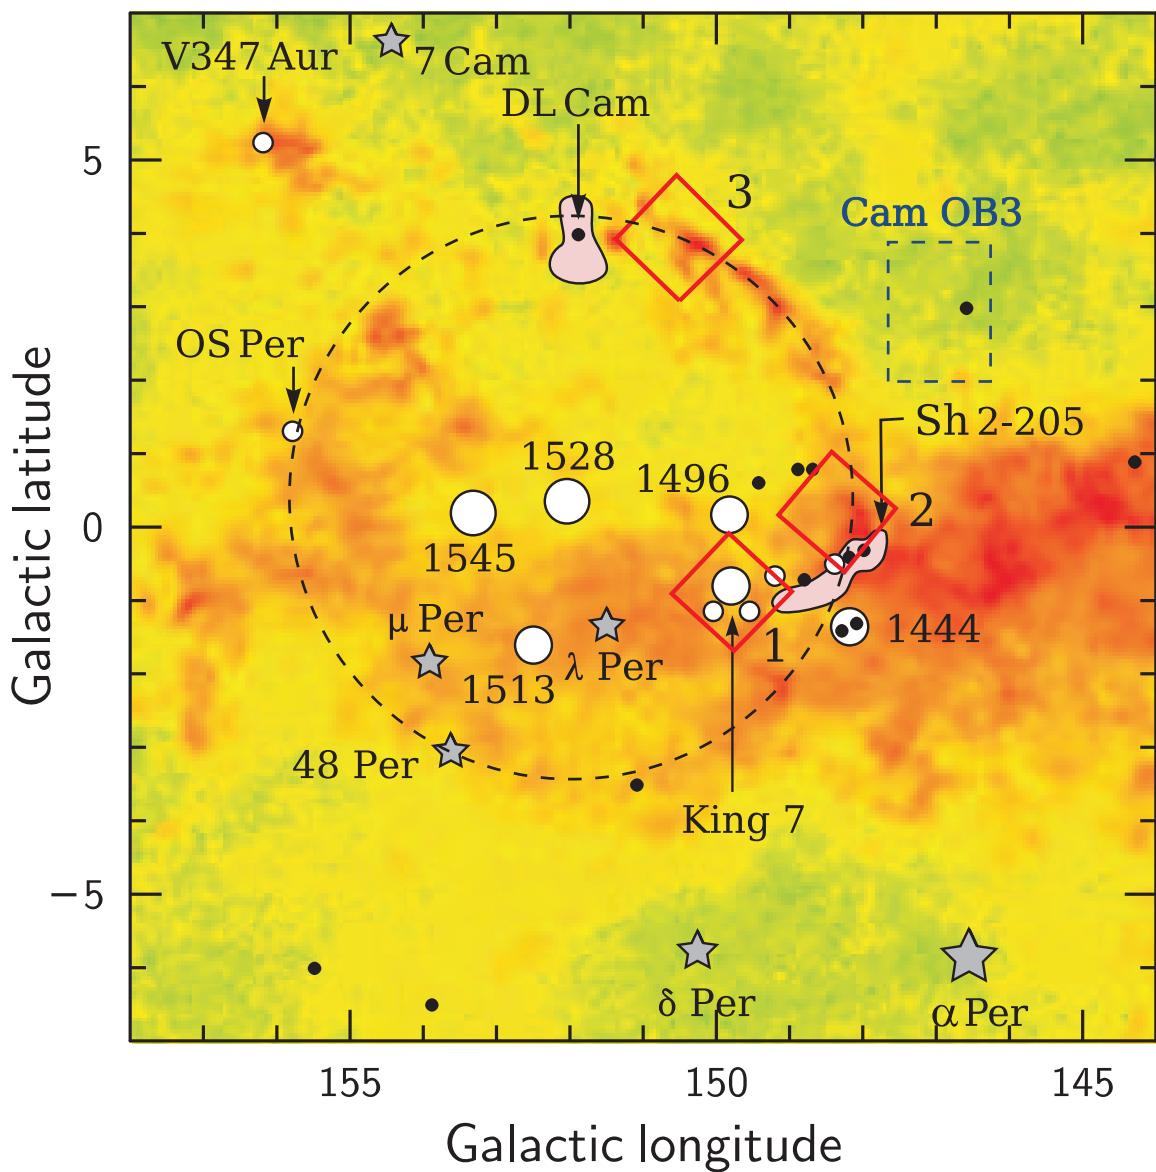

Figure 0.1.: Dust clouds in Camelopardalis from Dobashi et al. (2005). Three areas selected for investigation in this thesis are marked by squares. White large circles designate positions of open clusters, whose NGC numbers are indicated.

surrounding clouds, named cores, which are the supposed progenitors of young stars. Some of these objects are included in the catalogue of optically selected cores by Lee & Myers (1999). They were also observed with the Planck and Herschel observatories in the submillimeter and the far-infrared spectral regions (Juvela et al. 2012). About 30 far-infrared sources in the area of LDN 1400 and other nearby clouds were identified in the IRAS point-source catalogue by Clark (1991). Harjunpää et al. (1999) investigated polarization of stars in some directions of the LDN 1400 complex.

Distances to the chain clouds are known with a very low accuracy. The first estimate of their distance was probably published by Snell (1981). As the author explains, the estimate was done from the interstellar extinction A_V vs. distance d plot constructed for the stars with known B, V photometry and MK spectral types in a $20^\circ \times 20^\circ$ region centred on the cloud. Although a value of $d = 170$ pc has been attributed to a small cloud in the group (LDN 1407, the size $8' \times 8'$), actually this distance can be related to a much larger cloud complex. However, this distance should be of low accuracy since the stars with B, V photometry and MK spectral types in this region are rather scarce. This distance value (with nothing better available) has been used for decades in many investigations of the dust and molecular clouds in the whole chain. For the group of the chain clouds around LDN 1394, a distance value of 0.66 kpc was obtained by Juvela et al. (2012) applying a statistical method based on the Besançon (Robin et al. 2012) stellar population synthesis model and the 2MASS photometry data¹.

In several directions of the Camelopardalis dark clouds, the interstellar extinction was investigated by Zdanavičius et al. (1996, 2001); Zdanavičius & Zdanavičius (2002a,b, 2005); Zdanavičius et al. (2005) using seven-colour photometry in the Vilnius system and photometric classification of stars in spectral and luminosity classes. A common property of all areas is the extinction rise at 120–150 pc, reaching A_V about 1.5–2.5 mag at 1 kpc. Thus, the Camelopardalis clouds are located almost at the same distance as the Taurus-Auriga star-forming region; see also the review article in the “Handbook of Star Forming Regions” (Vol. 1) by Straižys & Laugalys (2008).

Distances to dust clouds can be also estimated from interstellar line intensities observed in the spectra of foreground stars and the stars immersed in the cloud, usually of spectral classes B and A. The most detailed investigations of interstellar Na I D lines and Ca II H+K lines in the solar vicinity were published by Welsh et al. (1994), Sfeir et al. (1999), Vergely et al. (2001, 2010), Lallement et al. (2003, 2014), Welsh et al. (2010) using the Hipparcos distances. In the general direction of Taurus and Auriga, the concentration of neutral gas is seen in the 80–150 pc distance range that can be associated with the boundary wall of the rarefied local cavity region around the Sun.

The TGU 994 P1 cloud is covered by one of the fields of the APOGEE² spectral survey (Bovy et al. 2014) of red clump giants (RCGs). From 155 RCGs in the field, 30 are located within our area. These stars are important tracers of the extinction at large distances, but they are lacking at the distances of cloud LDN 1400.

According to Dame et al. (1987, 2001), column densities and radial velocities of CO in some direc-

¹ In Table 1 of Juvela et al. (2012), the identification of the cloud LDN 1400 is not correct. It is located in the same area, called G150.47+3.93, as the LDN 1399 cloud.

² Apache Point Observatory Galactic Evolution Experiment

tions of the 2nd galactic quadrant exhibit two distinct layers at 800 pc and 300 pc from the Sun. The more distant layer, with the LSR velocity -12 km/s, is related to the chain of OB associations at the outer edge of the Local Arm belonging to the Gould Belt. The closer layer with LSR velocity close to zero is related to the expanding gas ring discovered by Lindblad et al. (1973) from observations of neutral hydrogen; see also Lindblad (1974). In the direction of Cam-Per-Tau the Lindblad Ring can be also related to the Per OB3 (or α Per) association ($d = 177$ pc) and the Cas-Tau moving group of B-type stars (d from 125 to 300 pc); the distances are from de Zeeuw et al. (1999).

The H II region Sh2-205 (Sharpless 1959) is the brightest northern clump of a large H II region at the Perseus and Camelopardalis border with a diameter of about $3.5^\circ \times 4^\circ$. The star HD 24431 of spectral class O9 ($V = 6.7\text{--}6.8$ mag), located close to its center, is considered as the main ionizing source of the nebula. The strongest emission spots in $H\alpha$ are observed around HD 24431 – the nebula [GS55] 34 (Gaze & Shain 1955) and in the northern clump (Sh2-205). It is doubtful that HD 24431 is the only ionizing star of this huge group of nebulae. Since no more O-type stars were known in the vicinity, the following early B-type stars have been considered: HD 23675 (B0 III), ALS 7793 (B1 V) and HD 24094 (B1 III), see Avedisova & Kondratenko (1984); Foster & MacWilliams (2006); Romero & Cappa (2008). The last star is at the center of the H II region Sh2-205, its spectral type is B1 III (Bouigue 1959), B2 τ (Rydström 1978), B1 IV (Zdanavičius et al. 2001), B1 V (De Cat et al. 2007).³ Different spectral classes are given in the HD catalogue, B8, and by Johnson (1956), B6. In these cases the star might be misclassified because of interstellar Ca II lines, or maybe its spectrum is variable. The star is known to have variable brightness; in the General Catalogue of Variable Stars its name is CY Cam, the amplitude is about 0.1 mag and the period is 1.05 d. It can be either a β Cephei pulsating star or a contact eclipsing binary of type EW (Duerbeck 1997; De Cat et al. 2007).

Distances to the H II region Sh2-205 and its southern extension, [GS55] 34, are known with a low accuracy. All the authors agree that HD 24431 is of spectral class O9, but the luminosity class of the star is rather uncertain: V (Conti & Alschuler 1971), IV-V (Morgan et al. 1953), III (Sota et al. 2011). This places the star (and the H II region) somewhere between 650 and 950 pc from the Sun. The star is a close binary (WDS J03556+5238 AB, $\Delta m = 3$ mag, sep = $0.7''$), and this can be the reason of luminosity errors. Kinematic distances to the nebulae, determined from radial velocities of $H\alpha$, HI or CO lines in the related clouds, combining them with the rotation curve of the Galaxy, are even more contradictory (Blitz et al. 1982; Fich & Blitz 1984; Fich et al. 1990; Foster & MacWilliams 2006; Foster & Brunt 2015).

In the vicinity of the H II region, as well as to north-east of its northern part, a number of dark clouds are observed. In the Dobashi et al. (2005) atlas and catalogue of dark clouds they are named as the P7 and P8 clumps of the cloud TGU H942. These clumps are parts of the dust ring of a diameter of 8° located at the edge of the Camelopardalis and Perseus constellations, identified by Straizys & Laugalys (2007a, 2008). The clump P8 is located between the Sh2-205 and [GS55] 34

³ The last two spectral types are determined from multicolour photometry in the Vilnius and Geneva photometric systems, respectively.

nebulae, while the clump P7 is located about 0.4° north-east from the northern edge of Sh2-205. Within these clumps and in their vicinities Dobashi (2011) has identified 14 smaller dust clouds on the basis of reddening and extinction of stars present in the 2MASS catalogue. Probably, most of these dust clouds (if not all) are located in the gas and dust complex to which the Sh2-205 nebula belongs. Thus, the investigation of distances to the dark clouds may help to find a more reliable distance to the nebula.

Photoelectric photometry of stars in the wide vicinity of Sh2-205 in the Vilnius seven-colour system has been started by Zdanavičius et al. (2001) and Zdanavičius & Zdanavičius (2002a) having the aim to determine distance to the Camelopardalis complex of dark clouds.

King 7 (King 1949) is a Hyades-age open cluster at $\alpha(2000) = 03^{\text{h}}59^{\text{m}}$, $\delta(2000) = +51^\circ48'$; $\ell = 149.77^\circ$, $b = -1.02^\circ$ near the Perseus and Camelopardalis border, between the H II regions Sh2-205 and Sh2-206 = NGC 1491 (Sharpless 1959). It is an object of the Perseus spiral arm at a distance of 1.9–2.2 kpc (Durgapal et al. 1996, 1997; Bukowiecki & Maciejewski 2008; Kharchenko et al. 2013). Its ionizing star is BD+50 886 ($V = 11.22$, spectral class O5 or O6).

In the 1.5×1.5 degree area centered on King 7 (Fig. 1.5), five more possible open clusters have been detected: BDS 61 (Bica et al. 2003), Juchert 19 (Kronberger et al. 2006), FSR 0660 or Majaess 41 (Froebrich et al. 2007ab), C440 and C441 (Camargo et al. 2015). The first of these clusters is located inside the H II region Sh2-206. All are heavily reddened clusters discovered in images of the 2MASS and WISE infrared surveys.

In the area of $1.5^\circ \times 1.5^\circ$ around King 7, several dark clouds are identified. In the Dobashi et al. (2005) atlas and catalogue of dark clouds they are named as the P2 ($8' \times 10'$) and P3 ($20' \times 22'$) clumps of the cloud TGU H989. The Dobashi (2011) catalogue shows a small dense cloud Dobashi 4059 ($5' \times 5'$) which almost coincides with P2. These clouds are parts of the dust ring of a diameter of 8° located at the border of the Camelopardalis and Perseus constellations, identified by Straizys & Laugalyš (2007a, 2008). In the Planck Cold Core catalogue (Planck Collaboration VII, 2011), which includes cold and dense condensations of the interstellar medium, we find one object in the vicinity of King 7 – a dense core PLCHECC G149.52-01.23, which coincides with the TGU H989 P2.

Except of Sh2-206, there is another H II region in the area: Anderson et al. (2015) have identified a distant H II region G149.746-00.199 located at about 12.5 kpc from the Sun. It is well seen in all IRAS and WISE images. Two reflection nebulae are present in the area: GN 03.53.0 (in the direction of the dark cloud TGU H989 P3 center) and GN 03.56.2 (in the direction of the Camargo 440 cluster (Magakian 2003).

In the broad vicinity of King 7, Zdanavičius et al. (2001) and Zdanavičius & Zdanavičius (2002a) have obtained photoelectric photometry of about 450 stars down to $V \approx 12.5$ mag in the Vilnius seven-colour system. The results of photometry were used to determine distances to the Camelopardalis complex of dark clouds (Zdanavičius & Zdanavičius 2002b).

Aim of the study

The main aim of this work is a comprehensive photometric investigation of the Milky Way region located at the Perseus and Camelopardalis border (Galactic longitude 147° – 157° , latitude from -5° to $+5^{\circ}$) in order to determine distances to the dust clouds and star formation activity in them.

Tasks of the study

1. CCD photometry of stars in a 1.5 square degree field in the vicinity of the dark cloud TGU H994.
2. CCD photometry of stars in a 1.5 square degree field in the vicinity of the H II region Sh2-205 (cloud TGU H942 area).
3. CCD photometry of stars in a 1.5 square degree field around open cluster King 7 (cloud TGU H989 area).
4. Two-dimensional photometric classification, determination of interstellar extinction and distance for the observed stars.
5. Determination of distances to dust clouds in the investigated areas.
6. Search for Young Stellar Objects (YSOs) in the investigated areas.

Scientific novelty

1. For about 4200 stars located in the region of a dust ring of a diameter of $\sim 8^{\circ}$, centered on the open cluster NGC 1528 multicolor photometry and two-dimensional spectral classification have been done for the first time.
2. The distribution of interstellar dust versus distance in different parts of investigated areas is provided.
3. Interstellar extinction and distances for 3313 stars and dark clouds are determined.

4. 96 new YSOs are identified in the investigated areas.
5. A new infrared cluster SCB 1 was discovered.

Practical importance

The distances to dust clouds that comprise the dust ring described in Straižys & Laugalys (2007a, 2008) were poorly known. The results of this work allowed to get reliable distances to investigated dust clouds. The results of photometry and two-dimensional stellar classification of stars are available at the CDS. Our results will be important addition to astrometric data which will be obtained by the Gaia space observatory of ESA. The use of photometric data together with the Gaia parallaxes will increase accuracy of distances to dust clouds and the location of Galactic spiral arms in the anticenter direction.

Results and statements presented for defence

1. The dark cloud TGU H994 is located at a distance of 140^{+36}_{-31} pc.
2. The dark cloud TGU H942 located in the vicinity of H II region Sh2-205 is composed of two layers – one located at 130^{+35}_{-27} pc, second at 500–600 pc.
3. The dust cloud TGU H989 located in the vicinity of open cluster King 7 is composed of at least two layers - one is located at a distance of 250^{+65}_{-52} and the second – at 1.3–1.5 kpc.
4. 118 (96 newly identified) YSOs show that active star formation is present H II region Sh2-205 and cluster King 7 areas.
5. A new infrared cluster SCB 1 was discovered in the vicinity of H II region Sh2-205.

Personal contribution

The author has chosen the optimum boundaries of the investigated areas, took part in most CCD observations at the Moletai Observatory (Lithuania) and Mount Graham International Observatory (USA). The author also took part in the reduction of CCD data, photometric classification of stars, the interstellar extinction analysis, the literature analysis and the preparation of all published articles. Personal contribution of the author to the results and publications presented in this thesis is no less than 50 percent.

Thesis outline

The dissertation consists of Introduction, five chapters, Conclusions, References, and Appendix.

Chapter 1 presents the description of observational material obtained with the Maksutov and VATT telescopes.

Chapter 2 describes the methods used for two-dimensional classification of stars.

Chapter 3 describes the method used for the determination of Interstellar extinction and distances to dust clouds.

Chapter 4 deals with star formation activity in the investigated areas.

Chapter 5 provides the data analysis and the results in the investigated fields and compares the results with the results obtained by other authors.

Chapter 1

Observational data

Observational data of this work cover three areas in the vicinity of the dust ring, described in Straizys & Laugalys (2007a, 2008) – dark cloud TGU H994 area, H II region Sh2-205 area (vicinity of dark cloud TGU H942 clumps P7 and P8) and star cluster King 7 area (vicinity of dark cloud TGU H989 clumps P2 and P3). Wide field CCD photometry was obtained with the Maksutov 35/51 telescope of the Molėtai Observatory of Vilnius University for three areas (TGU H994, Sh2-205 and King 7). The exposures were acquired in the *Vilnius* system *UPXYZVS* filters with a diameter of 50 mm. The filters *X*, *Y*, *Z* and *S* are interference filters (color glasses are used to remove light outside the transmittance maxima), and the ultraviolet *U* and *P* filters and the green *V* filter are cemented only from color glasses. Additionally, the red leak of the *U* filter is blocked by means of interference coating.

Maksutov telescope is equipped with a VersArray 1300B liquid nitrogen cooled camera. This liquid nitrogen cooled camera has a backside-illuminated 1340×1300 pixel chip (pixel size $20 \times 20 \mu\text{m}$) with Unichrom UV-enhancement coating (see Zdanavičius & Zdanavičius 2003 for details). In the telescope focus, the image scale is $3.38''$ per pixel, which gives a sky coverage of $1.26^\circ \times 1.22^\circ$. To exclude the influence of some defective pixels, part of the exposures were taken with a slight (about 30 pixels) shifts in *x* and *y* directions.

Deeper photometry in the same system but in smaller areas was obtained with the 1.8 m VATT telescope of the Vatican Observatory in Mount Graham International Observatory (Arizona) USA in the areas of the dark cloud TGU H994 and the H II region Sh2-205. The telescope is equipped with a 4K backside illuminated CCD camera and liquid nitrogen cooling. The camera contains a 62×62 mm chip which gives a $13'' \times 13''$ field of view, with a scale of $0.38''$ per pixel (binned 2×2). Flat-field and bias corrections were applied using the IRAF package¹. To extract the instrumental magnitudes, the aperture photometry mode was used. A detailed description of flatfielding and photometry routines can be found in Zdanavičius et al. (2008).

Due to low resolution of the Maksutov telescope, a number of stars in the catalogs appear as unresolved or partly resolved visual binaries. Therefore we checked our Maksutov stars by examining their images in the red DSS2 atlas provided by the SkyView Virtual Observatory².

¹ IRAF package (<http://iraf.noao.edu>) is distributed by the National Optical Astronomy Observatory, USA.

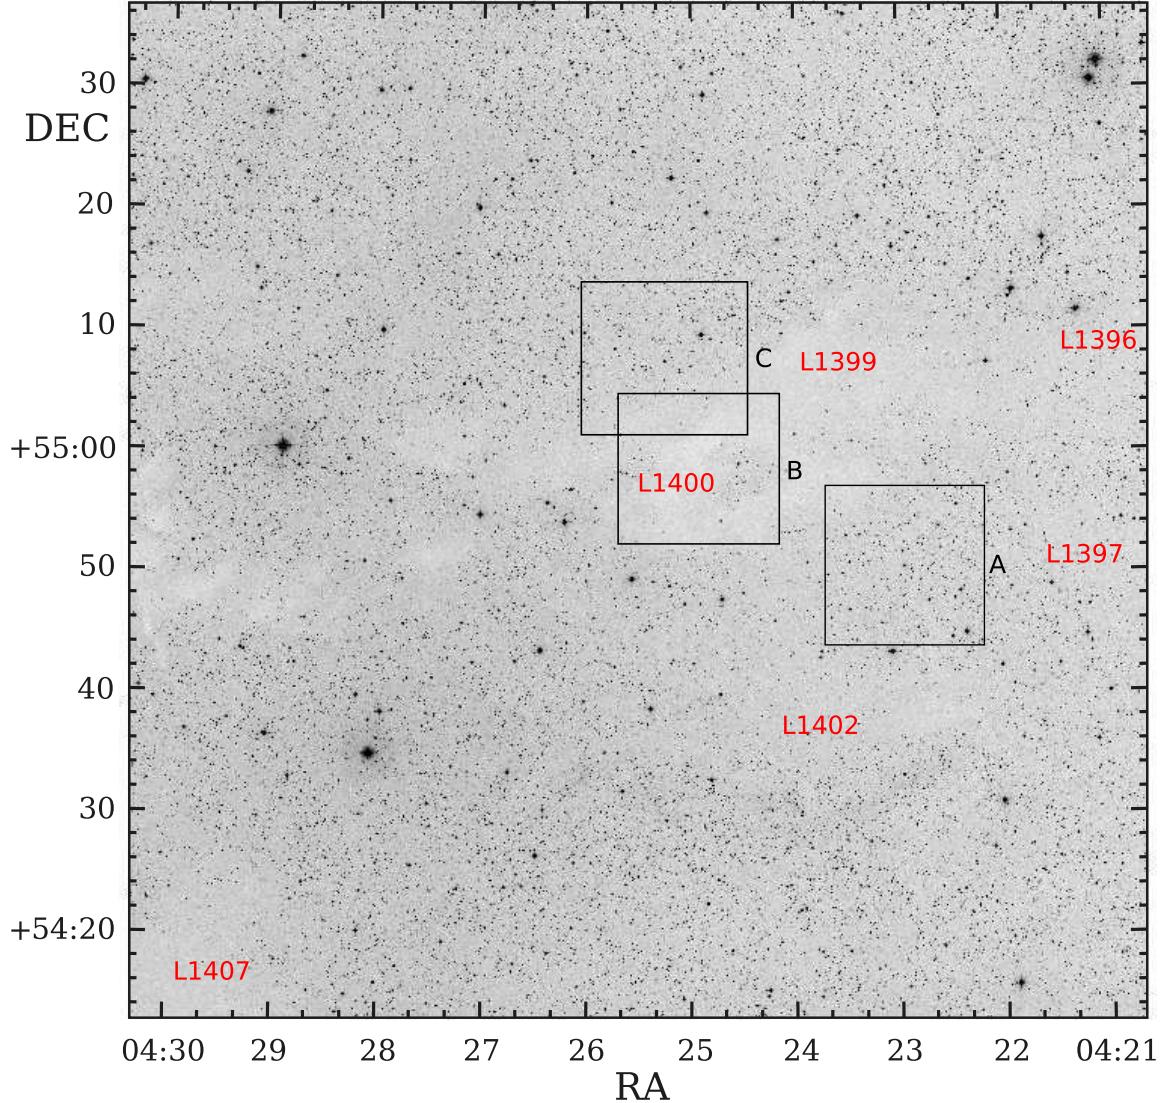

Figure 1.1.: Map with the observed dark cloud TGU H994 P1 area in the red filter (DSS1 Red from the SkyView Virtual Observatory). The three smaller squares were observed with the VATT telescope to fainter magnitudes.

1.1. Dark cloud TGU H994 P1 area

The investigated area (Fig. 1.1), covers 1.5 square degrees with the center at $\alpha(2000) = 04^{\text{h}}25.5^{\text{m}}$, $\delta(2000) = +54^{\circ}55'$; $\ell = 150.53^{\circ}$, $b = +3.96^{\circ}$.

The area includes the dark cloud TGU H994 P1 (Dobashi et al. 2005), also known as LDN 1399, LDN 1400 and LDN 1402 (Lynds 1962). These clouds are a part of the chain of dark clouds from LDN 1387 to LDN 1439 located in the southern Camelopardalis, close to the Perseus border.

1.1.1. Observations with the Maksutov telescope

Seven-color CCD photometry in the area shown in Fig. 1.1 was obtained in October of 2010.

Table 1.1.: Log of Maksutov observations of the dark cloud TGU H994 P1 area. The first two columns give the filter name and its mean wavelength. The numbers of multiple frames with the same exposure length are given in brackets.

Filter	λ_0 nm	min/sec	Exposure length and the number of frames
<i>U</i>	345	min	30 (2), 8 (2), 2 (2) 0.5 (4)
<i>P</i>	374	min	25 (2), 6 (2), 1.5, 1 (5)

16.00–17.00	72	0.020		0.054	0.105	0.037	0.039	0.042
17.00–18.00	5	0.026			0.102	0.054	0.049	0.061

In total, 67 frames of the area (Table 1.1) with different exposure lengths were obtained. Since the investigated area has no photoelectric standards in the Vilnius system, the standard stars from the Sh2-205 area were applied. Short tie-in exposures of both areas in all filters were obtained at nights with stable transparency. The transformation equations to the standard system were the same as in King 7 and Sh2-205 areas.

1.1.2. The catalog

Magnitudes and colors were determined for 727 stars down to $V = 17$ mag. The internal accuracy of the catalog for ten magnitude intervals is given in Table 1.2.

Spectral and luminosity classes are given for the majority of stars down to $V = 16$ mag (Fig. 1.2). The classification methods are described in Chapter II. In calculating of interstellar reddening-free Q -parameters, the normal interstellar reddening law was applied.

The results of photometry and classification are given in Table A.1. The catalog is also accessible at the Strasbourg Data Center. The columns give the following data: star number, equatorial

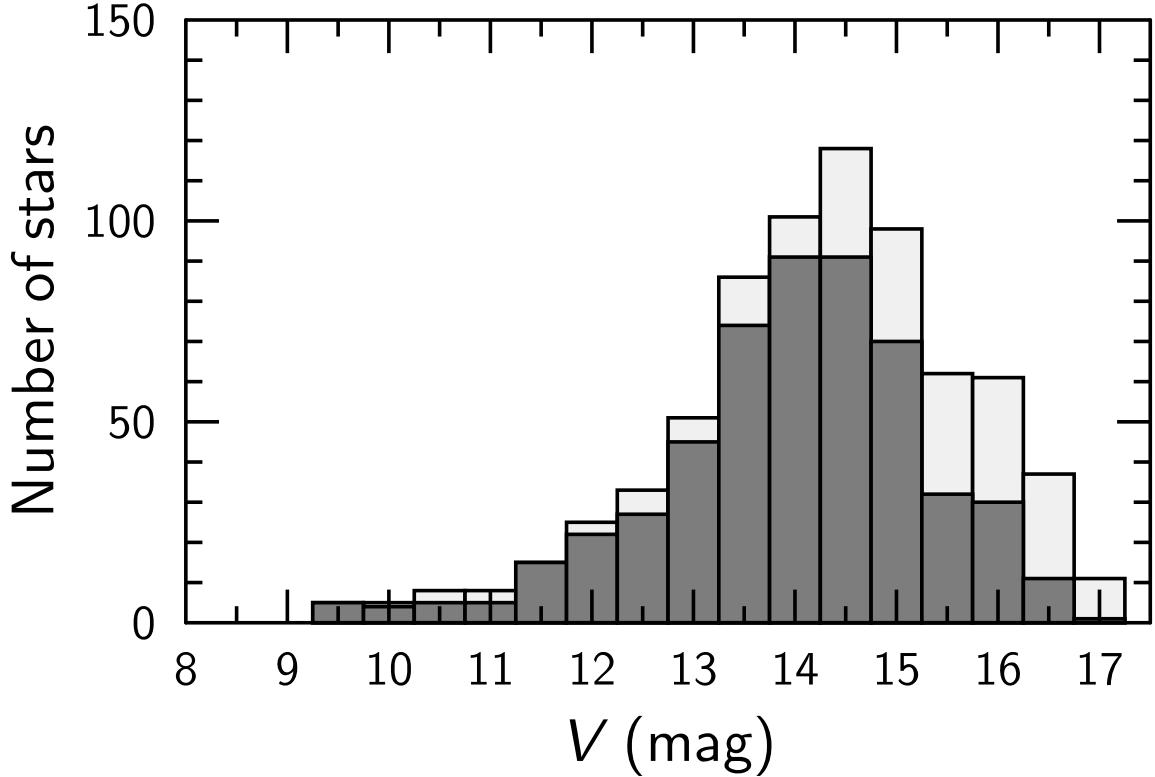

Figure 1.2.: Distribution of the Maksutov measured stars in apparent magnitudes in the dark cloud TGU H994 P1 area. The dark parts of the columns correspond to stars with two-dimensional classification.

coordinates J2000.0 from PPMXL (Roeser et al. 2010), magnitude V , color indices $U-V$, $P-V$, $X-V$, $Y-V$, $Z-V$ and $V-S$, photometric spectral type in the MK system, interstellar extinction A_V and the distance d in pc. The color indices with $\sigma = 0.05\text{--}0.10$ mag are marked by colons. In the column of spectral types, optical binaries with separation $<7''$ and the stars with asymmetrical images, i.e., binaries with separation $<2''$, are marked by double asterisks. Spectral classes are given in lower-case letters to indicate that they are determined from photometric data. Some additional information on identification, variability and spectral types, taken from the SIMBAD database and other sources, is given in the notes. The ID numbers of stars having notes at the end of the catalog are marked by asterisks.

1.1.3. Observations with the 1.8 m VATT telescope

Additionally, for the classification of fainter stars down to $V \approx 20$ mag, we applied Vilnius photometry in three $12' \times 12'$ areas located at the edges and within the LDN 1400 cloud. The areas are framed in Fig. 1.1 and their central coordinates are given in Table 1.3.

CCD observations in the Vilnius system were obtained in November and December 2014 and January 2015. In each area we processed about 70 frames obtained with the exposures from 30 minutes to 5 seconds. Instrumental color indices were transformed to the standard system with color equations obtained from observations of the cluster M67 (Laugalys et al. 2004). The stars measured

Table 1.3.: The three $12' \times 12'$ areas observed with the 1.8 m VATT telescope (see Fig. 1.1)

Area	α (2000)	δ (2000)	Number of stars
LDN 1400 A	04:22:58	+54:51:24	438
LDN 1400 B	04:24:32	+54:58:41	56
LDN 1400 C	04:25:15	+55:07:08	370

with the Maksutov telescope served as zero-point standards of magnitudes and color indices. All frames were processed with the IRAF program package in the aperture photometry mode.

1.1.4. The catalog

The catalog of photometric data for 855 stars down to $V \approx 20$ mag was compiled and is presented in Table A.2. The catalog is also accessible at the Strasbourg Data Center. The columns provide the same information as in Table A.1. The suspected metal-deficient stars are designated as md:, and the metal-rich stars (Am) as mr:. The coordinates are from the PPMXL catalogue (Roeser et al. 2010) rounded to two decimals of time second and to one decimal of arcsecond.

The r.m.s. errors of the magnitudes V and color indices $X-V$, $Y-V$, $Z-V$ and $V-S$ down to $V = 16$ mag are usually lower than 0.02 mag, and the errors of $U-V$ and $P-V$ are approximately twice as large. At $V > 19$ mag, the accuracy of photometry in the ultraviolet, especially for heavily reddened stars, is too low for reliable classification of stars earlier than K. For most of these stars the $U-V$ and $P-V$ color indices are not given. Color indices with $\sigma = 0.05\text{--}0.10$ mag are labelled with colons. The stars found to be binaries or having asymmetric images were not classified in luminosity classes, and in the column of spectral types these stars are designated with double asterisks.

1.2. H II region Sh2-205 area

The center of the second investigated area (Fig. 1.3), is at α (2000) = $03^{\text{h}}57.0^{\text{m}}$, δ (2000) = $+53^{\circ}40'$; $\ell = 148.34^{\circ}$, $b = +0.21^{\circ}$. It covers partly the northern end of the Sh2-205 nebula. This nebula is located at a distance of about 1.0 kpc and belongs to the Local arm. The dust map from Schlegel et al. (1998) shows a very uneven pattern of dust distribution in the area, the densest cloud coincides with the nebula in its western (right-hand) side. According to the atlas of Dobashi et al. (2005), there is one of the clumps of a large dust cloud TGU 942.

This area is a part of the $3^{\circ} \times 4^{\circ}$ size region investigated photoelectrically in the Vilnius system by Zdanavičius et al. (2001). Photoelectric photometry for more stars in the area was published by Zdanavičius & Zdanavičius (2002a,b). The stars from both these papers were used as standards in the present CCD work.

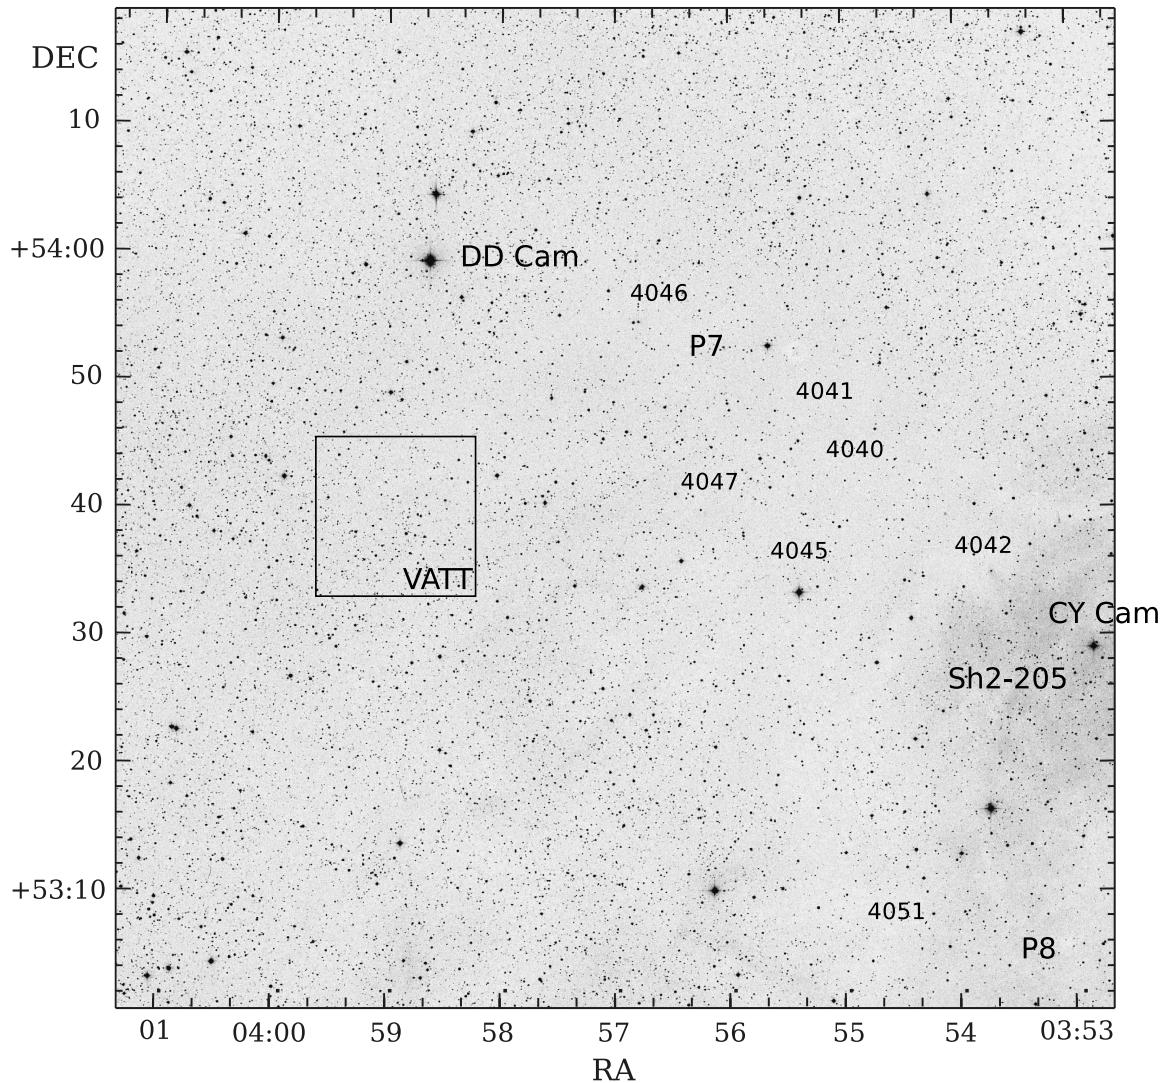

Figure 1.3.: Map with the observed H II region Sh2-205 area in the red filter (DSS1 Red from the SkyView Virtual Observatory). The small square shows the area observed with the VATT telescope to fainter magnitudes. Approximate positions of the northern part of the H II region Sh2-205, the centre of the dark cloud TGU H942 P7 and a part of the cloud TGU H942 P8 are designated. The four digit numbers designate positions of a few clouds identified by Dobashi (2011). The brightest star in the area is an eclipsing variable DD Cam (HD 24733). CY Cam is a possible ionizing star of Sh2-205.

Table 1.4.: Log of Maksutov H II region Sh2-205 observations. The first two columns give the filter name and its mean wavelength. The numbers of multiple frames with the same exposure length are given in brackets.

Filter	λ_0 nm	min/sec	Exposure length and the number of frames
<i>U</i>	345	min	30 (4), 10, 8 (2), 3, 2 (2), 1 (2)
<i>P</i>	374	min	25 (2), 6 (2), 2, 1 (2)
<i>X</i>	405	sec	1200 (2), 300 (2), 60 (2), 15 (2), 10
<i>Y</i>	466	sec	420 (2), 120 (2), 40 (2), 15, 10, 5
<i>Z</i>	516	sec	240 (2), 60 (2), 20 (2), 5 (2)
<i>V</i>	544	sec	900 (2), 240 (2), 60 (2), 15 (2), 10, 7
<i>S</i>	656	sec	240 (4), 60 (4), 20 (4), 5 (4)

1.2.1. Observations with the Maksutov telescope

Seven-color CCD photometry in the area shown in Fig. 1.3 was obtained in October of 2010.

In total, 70 frames of the area with different exposure lengths were obtained (Table 1.4.). The reduction method of the frames was the same as for TGU H994 region.

Zero-points of the transformation equations of instrumental magnitudes and color indices to the standard Vilnius system, were based on 13 stars in the field observed photoelectrically by Zdanavičius et al. (2001) and Zdanavičius & Zdanavičius (2002a,b). As the first stage, the linear transformation equations of magnitudes and color indices to the standard system, determined from observations of the M 67 cluster, were applied.

1.2.2. The catalog

Magnitudes and colors were determined for 922 stars down to $V = 17$ mag. The internal accuracy of the catalog is illustrated in Table 1.5, where the mean errors in V and color indices in nine magnitude intervals are given. The table shows that for the stars down to $V = 15$ the errors of $P-V$, $X-V$, $Y-V$, $Z-V$ and $V-S$ do not exceed 0.03, but the accuracy of $U-V$ becomes twice lower. The U and P magnitudes for the faintest stars with V between magnitudes 16.5 and 17 are not given.

Spectral and luminosity classes were estimated for about 85% of stars (Fig. 1.4). The two classification methods, COMPAR and QC0KLAS, are described in Stražys et al. (2013) and Milašius et al. (2013) and in Chapter 2 of this dissertation. In calculating of interstellar reddening-free Q -parameters the normal interstellar reddening law was applied.

The results of photometry and classification are given in Table A.3. The catalog is also accessible at the Strasbourg Data Center. The columns provide the same information as in Table A.1.

At the end of Table we give some additional information on identification, binarity, variability, spectral types, etc., taken from the SIMBAD database and other sources. The running numbers of stars having notes at the end of the catalog are marked by asterisks.

Table 1.5.: Internal accuracy of the H II region Sh2-205 Maksutov photometric catalog.

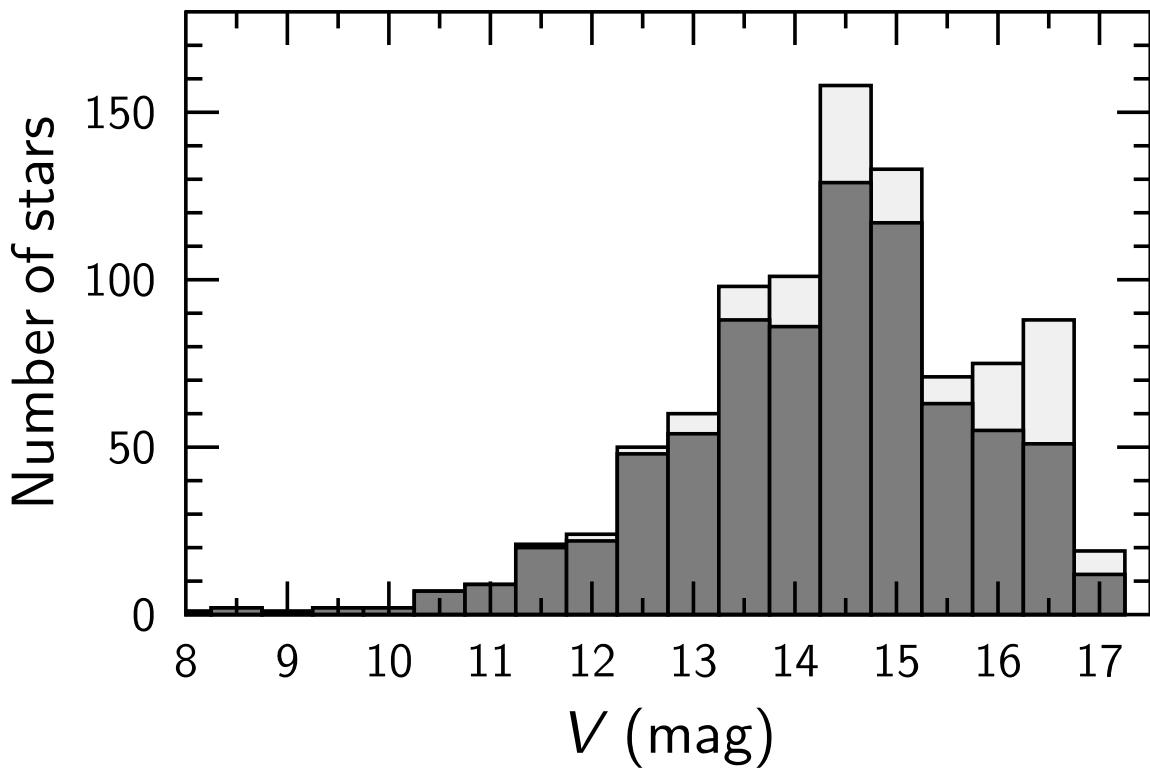

Figure 1.4.: Distribution of the Maksutov H II region Sh2-205 catalog stars in apparent magnitudes. The dark parts of the columns correspond to stars with two-dimensional classification.

1.2.3. Observations with the 1.8 m VATT telescope

For the classification of fainter stars down to $V \approx 19.5$ mag we applied Vilnius photometry in a $12' \times 12'$ area located in a region of intermediate transparency (Fig. 1.3) with the centre coordinates $\alpha(2000) = 03^{\text{h}}58.9^{\text{m}}$, $\delta(2000) = +53^{\circ}39'$; $\ell = 148.56^{\circ}$, $b = +0.38^{\circ}$. CCD observations in the Vilnius system in this area were obtained in December of 2013. 25 frames with exposures from 30 minutes to 6 seconds were processed with the IRAF program package in the aperture photometry mode. Instrumental color indices were transformed to the standard system with color equations obtained from observations of the cluster M67 (Laugalyš et al. 2004). The stars measured with Maksutov telescope served as zero-point standards of magnitudes and color indices.

1.2.4. The catalog

The catalog of photometric data for 302 stars down to $V \approx 19.5$ mag, and the results of photometric two-dimensional classification for about 80 % of them are given in Table A.4. The catalog is also accessible at the Strasbourg Data Center. The catalog contains the same information as Table A.2. The errors of magnitude V and color indices and also other notes are the same as in Table A.2. The coordinates are from the PPMXL catalogue (Roeser et al. 2010) rounded to two decimals of time second and to one decimal of arcsecond.

1.3. Star cluster King 7 area

The center of the third investigated area (Fig. 1.5), is at $\alpha(2000) = 03^{\text{h}}59.0^{\text{m}}$, $\delta(2000) = +51^{\circ}48'$; $\ell = 149.77^{\circ}$, $b = -1.02^{\circ}$. The area includes the P2 and P8 clumps of the dark cloud TGU H989 (Dobashi et al. 2005). The dust map from Schlegel et al. (1998) shows a complicated pattern of dust distribution in the area. The area is a part of the $3^{\circ} \times 4^{\circ}$ size region investigated photoelectrically in the Vilnius seven-color system by Zdanavičius et al. (2001). Photoelectric photometry for more stars in the area was published in Zdanavičius & Zdanavičius (2002a,b). These stars served as standards in the present CCD work.

1.3.1. Observations with the Maksutov telescope

Seven-color CCD photometry in the area shown in Fig. 1.5 was obtained in 2009 September.

In total, 61 frames of different exposure lengths were obtained (Table 1.6.).

The transformation of instrumental magnitudes and color indices to the standard *Vilnius* system, was based on 36 stars in the field observed photoelectrically by Zdanavičius et al. (2001) and Zdanavičius & Zdanavičius (2002a,b).

The (x,y) -coordinates of stars were transformed to right ascensions and declinations using the USNO-B1.0 catalog (Monet et al. 2003).

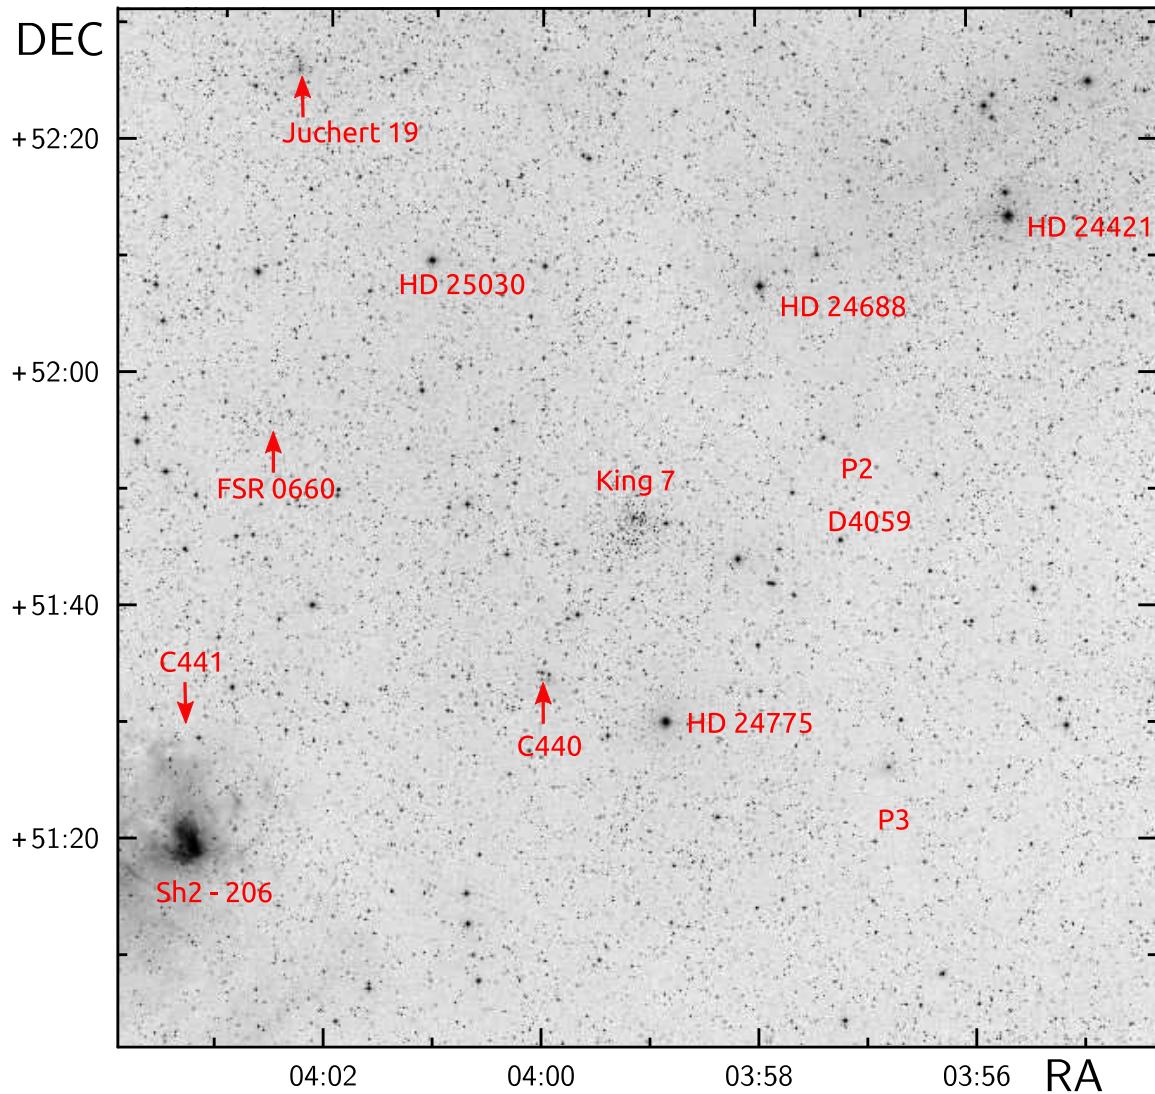

Figure 1.5.: Map of the observed King 7 area with Maksutov telescope (DSS1 Red from the SkyView Virtual observatory) P2 and P3 are the clumps of the dark cloud TGU H989; C440, C441, FSR 0660, Juchert 19 are infrared star clusters.

Table 1.6.: Log of Maksutov observations of the King 7 area. The first two columns give the filter name and its mean wavelength. The numbers of multiple frames with the same exposure length are given in brackets.

Filter	λ_0 nm	min/sec	Exposure length and the number of frames
<i>U</i>	345	min	30(2), 8(2), 2(2)
<i>P</i>	374	min	25(2), 5(2), 1(2)
<i>X</i>	405	sec	960(2), 300(2), 90, 70, 20(2), 15

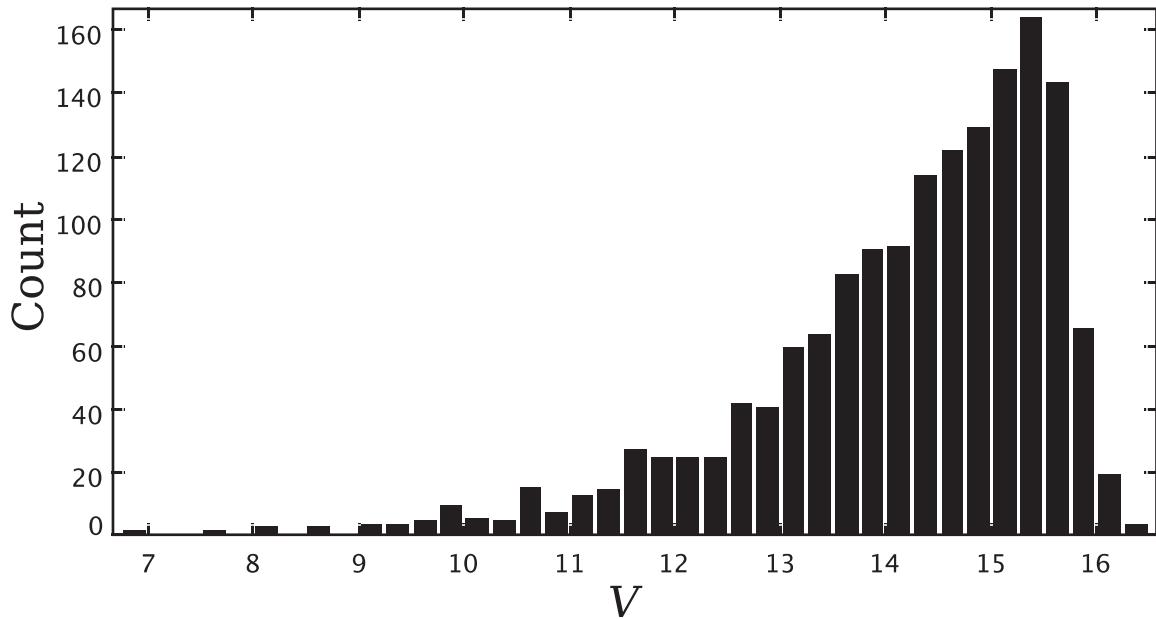

Figure 1.6.: Distribution of the Maksutov King 7 area catalog stars in apparent magnitudes.

1.3.2. The catalog

Magnitudes and colors were determined for 1549 stars down to $V = 17$ mag. The distribution of the catalog stars in apparent magnitudes is shown in Fig. 1.6. The internal accuracy of the catalog is illustrated in Table 1.7, where the mean errors in V and color indices in five magnitude intervals are given. The table shows that the accuracy better than 0.02 mag (or 0.05 and 0.03 mag in the case of $U-V$ and $P-V$, respectively) is valid for the stars brighter than $V = 15.5$. At $V \approx 16$, the accuracy of photometry is too low for a reliable classification of stars. At magnitude 17 for most stars the errors are ± 0.02 for V and ± 0.02 – 0.08 mag in other filters. The *U* and *P* magnitudes for the faintest stars are absent.

The results of photometry of 1549 stars down to $V \approx 16.0$ mag are provided at the Strasbourg Data Center. The columns list the same information as in Tables A.1. and A.3.

Table 1.7.: Internal accuracy of the photometric catalog.

V interval	n	σ_V	σ_{U-V}	σ_{P-V}	σ_{X-V}	σ_{Y-V}	σ_{Z-V}	σ_{V-S}
6.00–11.00	56	0.004	0.007	0.006	0.004	0.004	0.003	0.003
11.00–13.00	204	0.006	0.010	0.010	0.006	0.006	0.005	0.009
13.00–15.00	746	0.009	0.022	0.019	0.011	0.010	0.011	0.015
15.00–15.50	307	0.009	0.048	0.025	0.016	0.015	0.019	0.020
15.50–17.00	227	0.010	0.071	0.029	0.024	0.018	0.026	0.029

For most stars in the catalog spectral and luminosity classes are given. The classification methods are described in Zdanavičius et al. (2010).

Chapter 2

Two-dimensional classification of stars

Classification of stars in the Vilnius system is done by various reddening-free Q parameters and QQ diagrams calibrated in terms of spectral classes and absolute magnitudes and described in Straizys (1992). Q -parameters are defined by the equation

$$Q_{1234} = (m_1 - m_2) - (E_{12}/E_{34})(m_3 - m_4), \quad (2.1)$$

where $m_1 - m_2$ and $m_3 - m_4$ are color indices, and E_{12}/E_{34} are ratios of the corresponding color excesses. The extinction difference in two spectral regions defines a color excess, e.g. E_{B-V} in the BV system. The ratio of the total extinction in the V passband to the color excess E_{B-V} is $R = A_V/E_{B-V} = 3.15$ in the general Galactic dust layer.

2.1. Classification of stars in the TGU H994 P1, Sh2-205, and King 7 areas

For the two-dimensional spectral classification of stars (spectral and luminosity classes) two classification codes COMPAR and QC0KLAS later modernized and renamed to KLASQ were used.

1. The COMPAR code applies comparison of Q -parameters of stars in the area and individual standard stars. The code was composed by A. Kazlauskas and described by Straizys et al. (2013). When all six color indices are available, the method uses matching of 14 different interstellar reddening-free Q -parameters of a program star to those of about 8300 standard stars of various spectral and luminosity classes, metallicities, and peculiarity types from the General Photometric Catalog of Stars Observed in the Vilnius System (Straizys & Kazlauskas 1993) supplemented with new photoelectric observations. The E_{12}/E_{34} ratio slightly depends on spectral type, and this dependence is taken into account by approximations: the mean ratios of color excesses are used for preliminary classification, then the corrected ratios give new classification, etc. The ratios of color excesses corresponding to the normal interstellar reddening law are taken. The matching of Q -parameters leads to a selection of some standard stars with a set of Q s most similar to those of the program star. The match quality is characterized by σQ which depends on the differences of corresponding Q parameters of the program star and the standard star (ΔQ_i) and on a number of the compared Q parameters (n) (in our case, n = 14). For the stars observed with an accuracy of ± 0.01 mag, the σQ value is about ± 0.01 – 0.02 mag. In this case the match is considered to be good, and the MK

spectral type (spectral class + luminosity class) of the standard star may be assigned to the program star. Usually, we accepted for the program star the average spectral and luminosity classes of the five best-matching stars weighted by σQ^{-1} . If the matching accuracy is larger than 0.03 mag, the star remains not classified: such stars can be unresolved binaries or have peculiar spectral energy distributions. Two-dimensional classification of K and M stars can be obtained even without $U-V$ and $P-V$ color indices, containing the ultraviolet magnitudes U and P , and using only seven Q parameters. Sometimes it is difficult to separate K and M stars, especially K5–K7 and M0–M2 dwarfs. In this case the 2MASS JHKs or WISE photometry helps.

2. The QC0KLAS or KLASQ code, instead of standard stars with known MK spectral types, applies the intrinsic color indices for 300 types of two-dimensional MK types taken from the Stražys (1992) monograph. The code was composed by K. Zdanavičius and is described in Milašius et al. (2013). The classification code includes the following three stages:

- (1) 14 interstellar reddening-free Q parameters are calculated from the intrinsic color indices for 300 MK types. In calculation of the Q parameters, the ratios of color excesses corresponding to the normal interstellar reddening law are taken. The same Q parameters are calculated for the program stars. Next, for each program star these 14 Q parameters are matched up with the set of 300 standards to find the MK type which shows the least standard deviation;
- (2) The next classification stage is based on six intrinsic color indices which include the passbands X , Y , Z and V ($X-Y$, $X-Z$, $X-V$, $Y-Z$, $Y-V$ and $Z-V$). Differences of the observed color indices of a program star and the corresponding intrinsic color indices of the 300 MK standards are calculated giving the spurious "color excesses" which for convenience are all transformed to the values of interstellar dust mass x (in the scale when $A_V = x = 1$). The values of $x < -0.15$ are rejected. The analysis of x values for each program star (corresponding to different color indices) allows finding the standard for which the dispersion of the six x values is at minimum. This value of x should be close to the real interstellar dust mass which affects this star, and the corresponding spectral type can be accepted for the program star;
- (3) The accepted spectral type of a program star and its dust mass allows to deredden all color indices. We can compare the dereddened indices with the intrinsic color indices of a set of standard 300 MK types, find a minimum dispersion of six color indices and estimate again the spectral type of this program star.

Finally, the mean values of these three MK types are calculated. Their dispersion allows to estimate the classification reliability. Interstellar reddening and extinction for each of the classified stars is determined together with its spectral type.

In recent years K. Zdanavičius has updated the classification code. The number of stars used as standards for two-dimensional spectral classification have been increased and next to the σQ and σC parameters used, new parameter σA , describing interstellar extinction dispersion resulting from three color indices $X-Y$, $Y-V$, and $V-S$, has been added.

To verify the results of photometric classification of TGU H994 P1 region, Ulisse Munari obtained the spectra of 18 stars of the area down to $V = 12$ mag with the 1.22 m telescope at the Asiago

Table 2.1.: Stars classified from the Asiago spectra by the Gray & Corbally (2014) code MKCLASS and by visual inspection (U.M.). For the comparison, photometric spectral types obtained with two different codes (KLASQ and COMPAR) are listed.

Note. No. 76 (HDE 232940) is a new Be-type star (Chojnowski et al. 2015).

Observatory, Italy, equipped with a B&C spectrograph and a 600 lines/mm grating providing a dispersion of $1.17\text{\AA}/\text{pix}$ and a resolving power = 2.1 pix. The recorded spectra cover $3487 - 5885\text{\AA}$. Spectral classification of these stars, listed in Table 3, was accomplished with the computer program MKCLASS designed to classify stellar spectra on the MK system provided by Gray & Corbally (2014). Table 2.1 shows that in most cases differences between the spectroscopic and photometric spectral types do not exceed one to two spectral subclasses and one luminosity class. This gives us additional confidence in two-dimensional spectral types determined from Vilnius photometry.

As an independent check of the classification of the Asiago spectra by means of the Gray & Corbally (2014) code, U. Munari independently classified eight of them through a careful visual comparison of their calibrated spectra against the Yamashita et al. (1977) atlas of the representative stellar spectra in the MK system. For these stars (Nos. 8, 76, 279, 420, 565, 580, 668, and 683), differences between the spectral classification from photometry and from the Gray & Corbally (2014) code were the largest. The results, listed in Table 2.1, are in strong support of the MKCLASS code.

Chapter 3

Distance determination to dust clouds

For the classified stars we determined color excess E_{Y-V} , interstellar extinction A_V and distance d by the following equations:

$$E_{Y-V} = (Y - V)_{\text{obs}} - (Y - V)_0, \quad (3.1)$$

$$A_V = 4.16 E_{Y-V}, \quad (3.2)$$

$$5 \log d = V - M_V + 5 - A_V, \quad (3.3)$$

where V and $Y-V$ are the observed magnitudes and color indices. The intrinsic color indices $(Y-V)_0$ and absolute magnitudes M_V for a given spectral type are from Straizys (1992). The errors of color excess, extinction, and distances are described in Straizys et al. (2015). Typical errors of the extinction and distance are $\sigma(A_V)/A_V = \pm 0.06$, and $\sigma(d)/d = \pm 0.10$.

3.1. Distance to the dust cloud TGU H994 P1

For 584 stars from Table A.1 and for 447 stars from Table A.2 with reliable spectral and luminosity classes, color excess E_{Y-V} , interstellar extinction A_V , and distance d (in pc) were calculated with the (3.1), (3.2) and (3.3) equations.

In Eq. (3.2) the coefficient corresponds to the normal interstellar extinction law. The normality of the law was verified in the following way: (1) 123 B and A stars in the area were selected; (2) for these stars, $E_{B-V} = 1.32 E_{Y-V}$ values were calculated; (3) the E_{V-J} , E_{V-H} , and E_{V-K_s} values were calculated taking the intrinsic colors from Straizys (1992); (4) the R_V values were calculated from the ratios $E_{V-\lambda}/E_{B-V}$ with the equations from Fitzpatrick (1999); Fitzpatrick & Massa (2009) and Larson (2014). The resulting R_V values are between 2.92 and 3.12, i.e. close to the normal value 3.1.

The plot A_V vs. d for stars in the whole 1.5 deg^2 area up to 500 pc is shown in Fig. 3.1. The stars measured from the Maksutov telescope exposures are shown as black dots, and those measured from the VATT exposures are shown as yellow circles. The stars with spectroscopic MK types (Table 2.1) are plotted as blue crosses. The red vertical line designates the accepted cloud distance. The A_V vs. d plot for 584 stars in the same area up to 5.5 kpc is shown in Fig. 3.2. The two broken red curves show the limiting magnitude effect for stars of spectral types A0 V at $V = 15$ and 16 mag. Most stars are located below the last curve. Above it, at large distances, we find only a few stars of

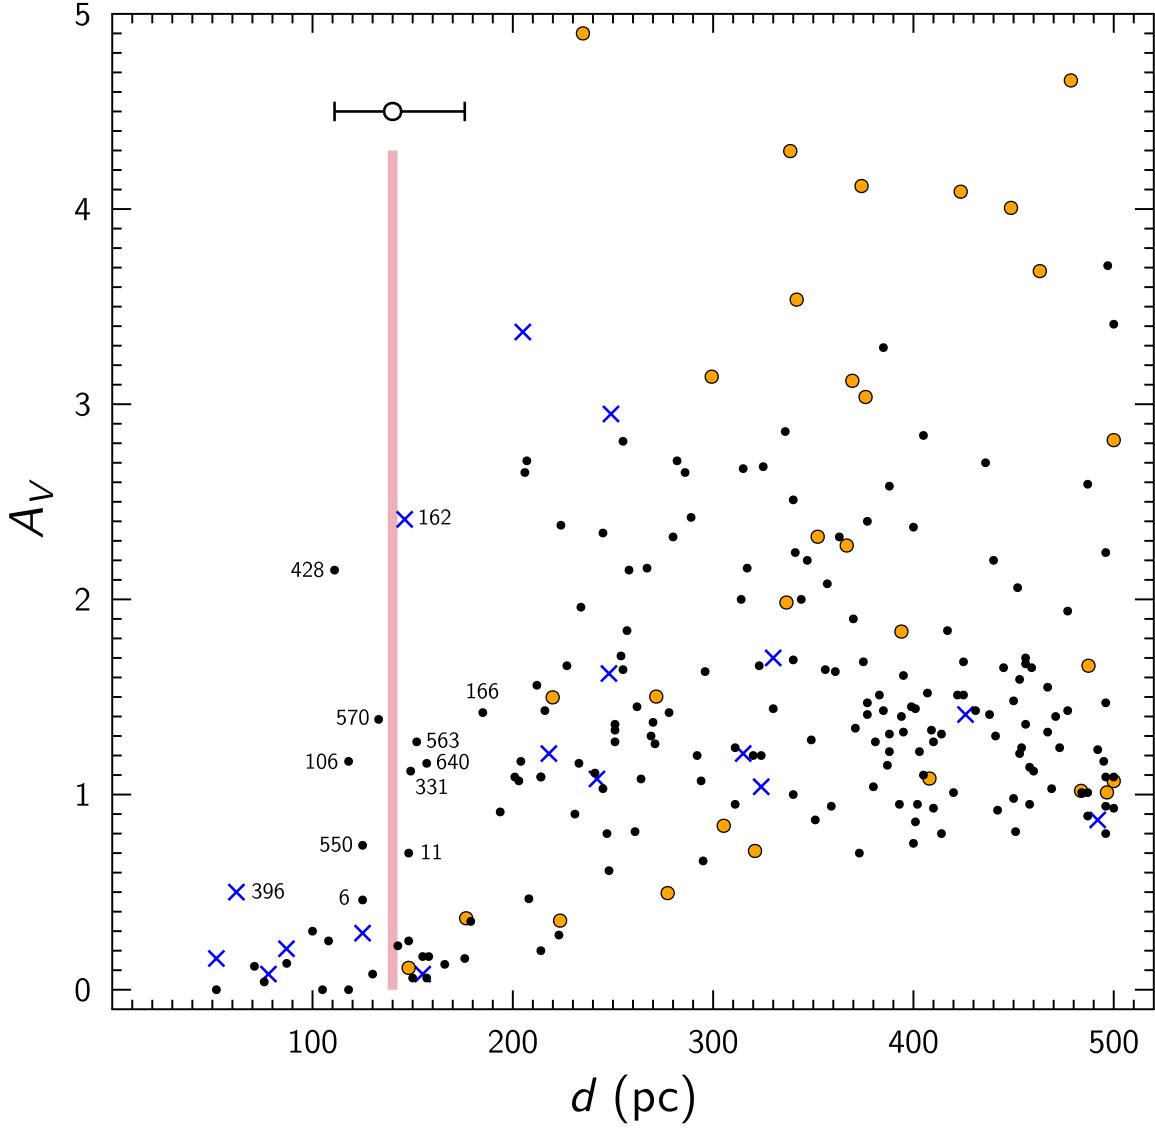

Figure 3.1.: Extinction versus distance for the investigated TGU H994 P1 area up to $d = 500$ pc. The stars, measured in the Maksutov telescope exposures, are plotted as black dots, and the stars, measured in the VATT exposures, are plotted as yellow circles. Blue crosses are the stars for which MK spectral classes were determined from their Asiago spectra (Table 2.1). The nearest reddened stars are labelled with their numbers in the Table A.1 catalogue. The red vertical line designates the accepted position of the dust cloud TGU H994 P1 at 140 pc (see the text). The 3σ error bar for this distance is shown.

spectral class B and M giants, which have absolute magnitudes brighter than A0 V. Fig. 3.3 shows the A_V vs. d plot for 416 stars up to 5.5 kpc in the three areas observed with the VATT telescope down to fainter apparent magnitudes.

The determination of distances to dust clouds located close to the Sun is difficult because the number of stars in the foreground and immediately behind the cloud is usually low, and most of them are K and M dwarfs. The beginning of the cloud should be signified by a sudden rise of the extinction at a certain distance. However, the apparent distance of the nearest reddened stars cannot be accepted

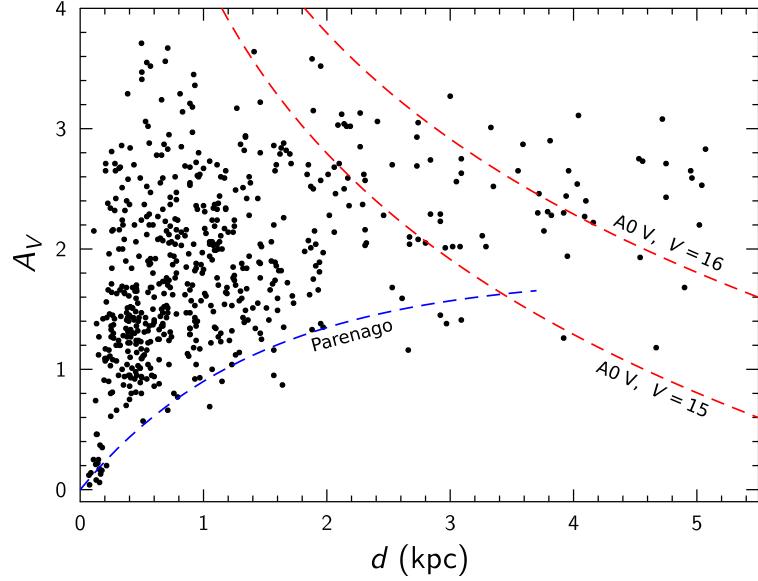

Figure 3.2.: Extinction versus distance for the investigated TGU H994 P1 area up to 5.5 kpc for 584 stars with two-dimensional classification, measured in the Maksutov telescope exposures. The two red broken curves show the limiting magnitude effect for A0 V at $V = 15$ and 16 mag. The exponential extinction formula of Parenago (1945) for the Galactic latitude $b = 4^\circ$, $A_V = 1.25 \text{ mag/kpc}$ and the scale height 100 pc is shown (blue broken curve).

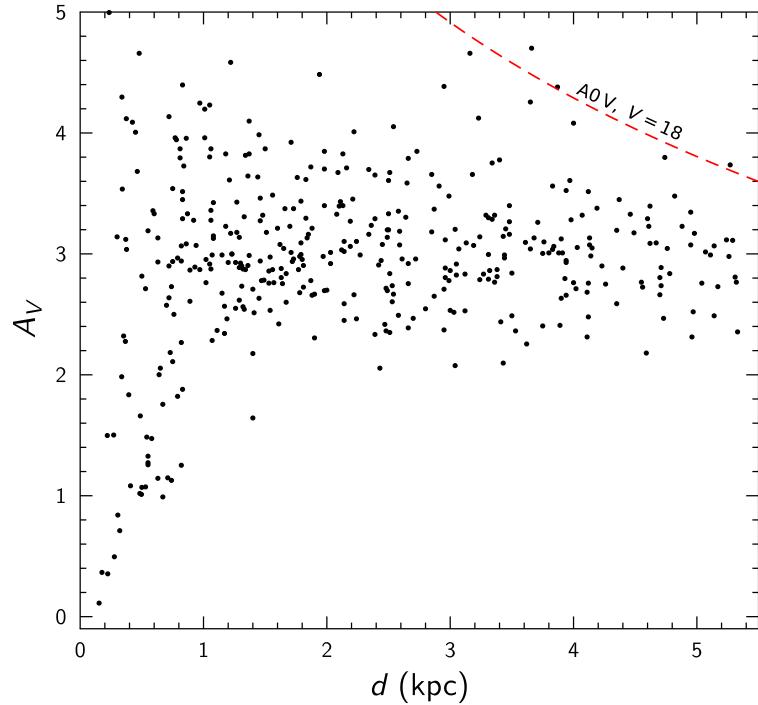

Figure 3.3.: Extinction versus distance in the three TGU H994 P1 $12' \times 12'$ areas for 416 stars with two-dimensional classification, measured in the VATT telescope exposures. The red broken curve designates the limiting magnitude effect for A0 V stars at $V = 18$ mag.

as the cloud distance, since their distances are affected by the errors of the observed magnitudes and colors, photometric classification errors, cosmic dispersion of the intrinsic colors, variations in the shape of the interstellar extinction law; some stars can be unresolved binaries.

In our case (Fig. 3.1), the distribution of stars with distance shows a significant increase of the extinction starting from ~ 110 pc. At about 200 pc the extinction values close to ~ 5 mag are being reached. Trying to understand where the cloud is located, we must analyse the possible distance errors for each reddened star. The largest source of distance errors are luminosity classes determined by photometric classification. In different ranges of spectral classes, these errors are somewhat different, but their typical value is close to $3\sigma = \pm 0.5$ mag. For K- and M-type dwarfs the photometric luminosity class is usually correct, but in the HR diagram they exhibit considerable intrinsic dispersion of their M_V values at a fixed intrinsic color or spectral class; see Perryman et al. (1995, 1997). An absolute magnitude error of ± 0.5 mag leads to the minimum and maximum apparent distances $0.79 d$ and $1.26 d$. As a result of these distance errors, stars move from the distance of the cloud to both sides, but they are easy to identify in the direction of negative distance errors (i.e. reddened stars moved to foreground) since in the direction of positive distance errors they become mixed with reddened background stars (except at A_V close to zero, see below).

At this point, we evaluate the distance to the cloud from the apparent positions of the reddened foreground stars. Since there is no information about their binarity, the stars are considered to be moved from the cloud distance mainly by the errors of their absolute magnitudes. Unfortunately, the close reddened stars in our sample are very scarce.

The reddened star with $A_V > 1$ mag that is nearest to us is No. 428 ($V = 13.47$, k1 V, $A_V = 2.14$ mag, $d = 111$ pc). This star is located only about $2'$ north of the cloud LDN 1400 edge. If this star has been moved to this apparent distance by the 3σ error, its real distance should be $111 \times 1.26 = 140$ pc (all distances are rounded to 1 pc). If star No. 428 is a binary or has been shifted shortwards by a larger distance error, the calculated cloud distance should be larger. If the star has been moved by a smaller distance error, its real distance, i.e. beginning of the cloud, should be smaller.

Another place in the A_V vs. d diagram is related to the unreddened or little reddened stars apparently located at larger distances than the cloud. If these stars have been moved to their apparent distances due to positive errors, then the real distance of the cloud should be smaller by a factor of 0.79. In Fig. 3.1, the stars with small extinction ($A_V < 0.2$ mag) extend to the apparent distance 180 pc, and this allows us to estimate the real cloud distance at $180 \times 0.79 = 142$ pc. This value is in agreement with the distance given by the foreground star No. 428.

If these considerations are real, the cloud distance is at 140 pc with 3σ errors -31 pc and $+36$ pc shown by the error bar in Fig. 3.1. Within this box, ten reddened stars with A_V between 0.5 and 2.3 mag are present. On the other hand, we are not sure that the entire investigated area is covered by a single cloud located at a fixed distance. The cloud complex can have considerable depth along the sightview, and in this case our results should correspond to different dust condensations.

The star No. 396 ($V = 10.15$, G9 V, $A_V = 0.50$, $d = 62$ pc), classified both from the Asiago spectra and from Vilnius photometry, also exhibits unusually large reddening for its distance. We suspect

this may be caused by an unseen red dwarf companion.

Figs. 3.2 and 3.3, which show the extinction vs. distance relations up to 5.5 kpc for the Maksutov and VATT telescopes, respectively, allow us to estimate the extinction run at large distances. The Maksutov results demonstrate a strong limiting magnitude effect at $V = 16$ mag. Therefore, the stars with large extinction values (up to ~ 3.7 mag) are only seen at distances closer than 2 kpc. In the VATT results, the limiting magnitude is close to $V = 19$ mag, and that is where we see the stars with A_V up to 5 mag and at larger distances. Most of the heavily reddened stars are located close to the dark cloud LDN 1400 (VATT areas B and C). In Fig. 3.3, the absence of stars with A_V lower than 2 mag can be explained by the fact that the VATT areas are located in directions with larger obscuration.

3.2. Distance to the dust clouds in the vicinity of the H II region Sh2-205

For 628 stars from Table A.3 and for 238 stars from Table A.4 with reliable spectral and luminosity classes, color excesses E_{X-V} , E_{Y-V} , and E_{V-S} were calculated as differences between the observed and intrinsic color indices taken from Straižys (1992). Then the excesses E_{X-V} and E_{V-S} were transformed to E_{Y-V} with the equations

$$E_{Y-V} = 0.58E_{X-V} \quad (3.4)$$

and

$$E_{Y-V} = 1.19E_{V-S}, \quad (3.5)$$

and the three values of E_{Y-V} were averaged. The interstellar extinctions A_V and distances d (in pc) were calculated with the equations (3.2) and (3.3). The coefficient in Eq.(3.2) corresponds to the normal interstellar extinction law. Normality of the law is based on the analysis of color excesses of B and A stars in the area TGU H994 P1. We have also found that the slope of the reddening line in the $J-H$ vs. $H-K_s$ diagram in both areas coincides. This means that the extinction law in the near-infrared is similar in both directions.

The plot A_V vs. d for 57 stars in the whole 1.5 deg^2 area with distances up to 250 pc is shown in Fig. 3.4. All these stars are measured from the Maksutov telescope exposures. A few stars in the same distance range measured from the VATT exposures are common in both catalogues. Two more possible K1–K1.5 dwarfs, Nos. 731 and 878, with $A_V = 3.6$ and 3.8 mag respectively, fall into the same distance range, but their classification and distances are of lower accuracy, thus we do not plot these stars in Fig. 3.4.

For the estimation of distance to the nearest dust cloud we applied the same method as in TGU H994 region: the obscured (reddened) stars with the smallest distances were considered to be located at a distance of the front side of the dust cloud, but scattered to lower apparent distances because of negative errors. The main source of the distance error is the absolute magnitude of the star which

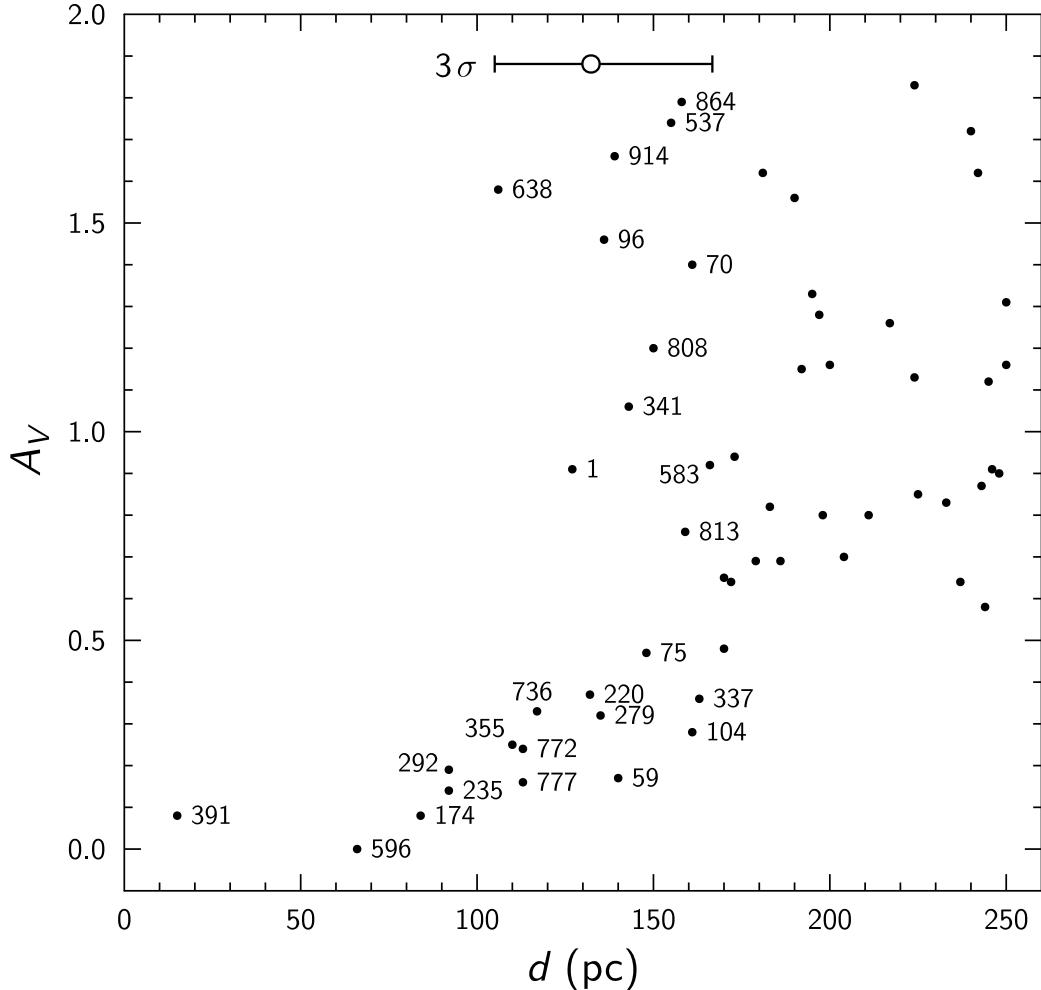

Figure 3.4.: Extinction versus distance for the investigated Sh2-205 area up to $d = 250$ pc. The stars up to 170 pc are marked with their numbers from Table A.3.

is estimated from its spectral and luminosity classes. We accept that the 3σ error of the absolute magnitude is 0.5 mag, and this corresponds to the scatter of distances by a factor of 1.26.

In Fig. 3.4 the nearest star with large extinction is No. 638 (g8.5 IV-V) at 105 pc. If this star has appeared at this apparent distance due to 3σ error of d , then its real distance should be 132 pc. This means that the distance to the nearest clouds in the area is close to 130 pc, i.e. by ~ 10 pc closer than the nearby cloud chain TGU H994 P1 also investigated in this work. However, we are not sure that all reddened stars within the error bar shown in Fig. 3.4 are at the same distance. The Camelopardalis clouds can have a considerable thickness along the sightline, which in the nearby Taurus complex is of the order of 25–30 pc (Loinard et al. 2011; Welsh et al. 2010; Lallement et al. 2014).

Surface distribution of the nearby reddened stars shows no relation to the surface density of the dust thermal emission across the Galaxy shown by the dust map from Schlegel et al. (1998) based on the IRAS and COBE/DIRBE 100 μ m observations. This means that the nearest dust layer at ~ 130

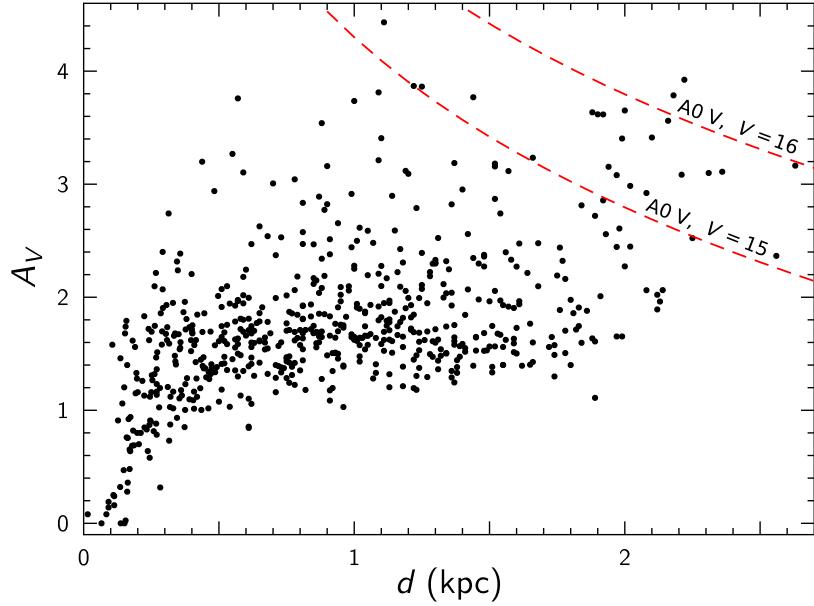

Figure 3.5.: Extinction versus distance for the investigated Sh2-205 area up to 2.6 kpc for 628 stars with two-dimensional classification, measured in the Maksutov telescope exposures. The two red broken curves show the limiting magnitude effect for A0 V at $V = 15$ and 16 mag.

pc covers more or less all the investigated area, and the dense clouds in the mentioned dust map are seen in the distant background.

The A_V vs. d plot up to ~ 2.5 kpc for the 1.5 deg^2 area is shown in Fig. 3.5 for 628 stars measured and classified from the Maksutov telescope exposures. The extinction run with distance, starting from the jump at 130 pc, continues to rise quite steeply up to 200–300 pc. At this distance it splits into two branches – the lower branch which remains at about the same extinction level (1.5–2.0 mag), and the upper branch which continues to rise up to ~ 3.5 mag at 500–600 pc. The maximum extinction is difficult to estimate since at large values of A_V the selection effect due to limiting magnitude starts to be effective, especially for A–F–G5 stars, see the limiting magnitude curves for A0 V stars. Behind the Perseus arm at 2.5 kpc the stars are mostly fainter than $V = 16$ mag, and they were rejected because of low accuracy of photometry and classification.

Fig. 3.6 shows a similar plot up to ~ 6 kpc for 238 stars measured and classified in the smaller VATT area of intermediate transparency. The red broken curve in the right upper corner show the limiting magnitude effect for the A0 V stars at $V = 18$ mag. The same curves are valid also for G5–K2 giants which have absolute magnitudes similar to A0 V stars. Because of the fainter limiting magnitude, some stars are measured and classified up to 5–6 kpc distances. Also, much higher extinctions up to 5 mag and more become accessible. At 500–600 pc the extinction jump up to $A_V = 3.5$ –4.0 mag seems to be present. Some rise of the extinction is also possible in the Perseus Arm at $d > 1.5$ kpc. Three stars with A_V close to 5 mag are observed within the Perseus arm but the stars with larger obscuration are absent because of the limiting magnitude effect.

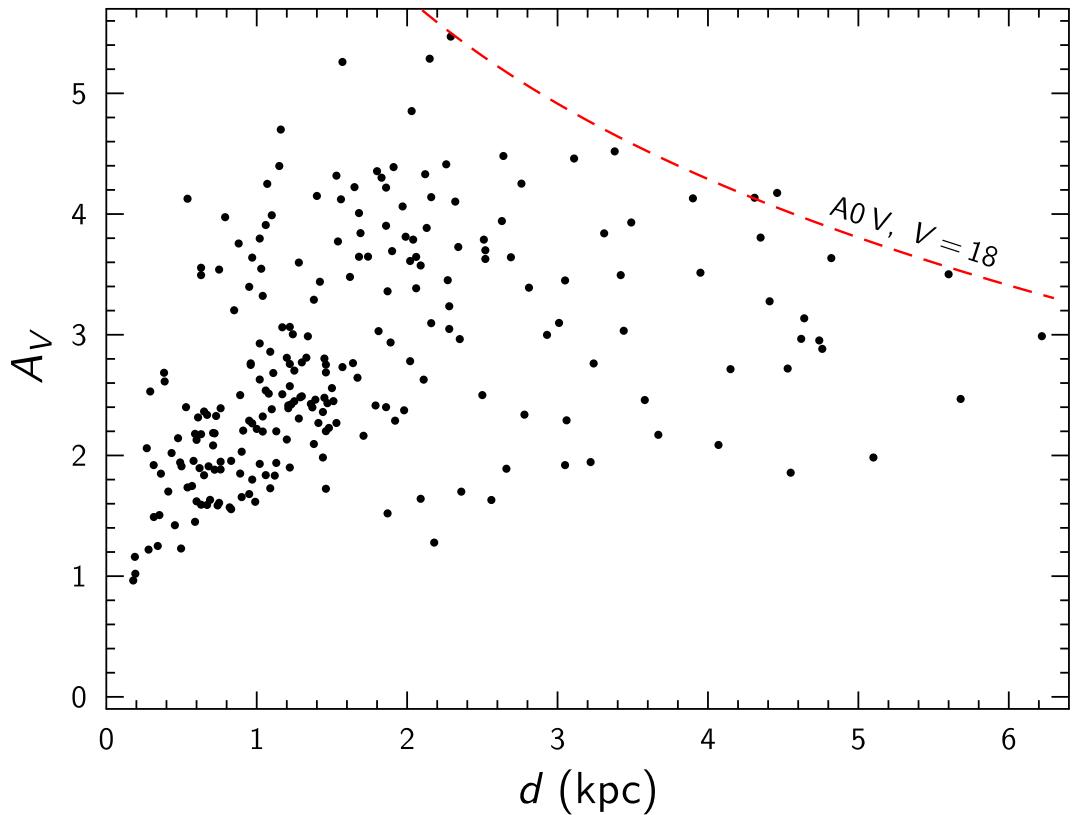

Figure 3.6.: Extinction versus distance for the investigated Sh2-205 area up to 6 kpc for 238 stars with two-dimensional classification, measured in the VATT telescope exposures. The red broken curve shows the limiting magnitude effect for A0 V at $V = 18$ mag.

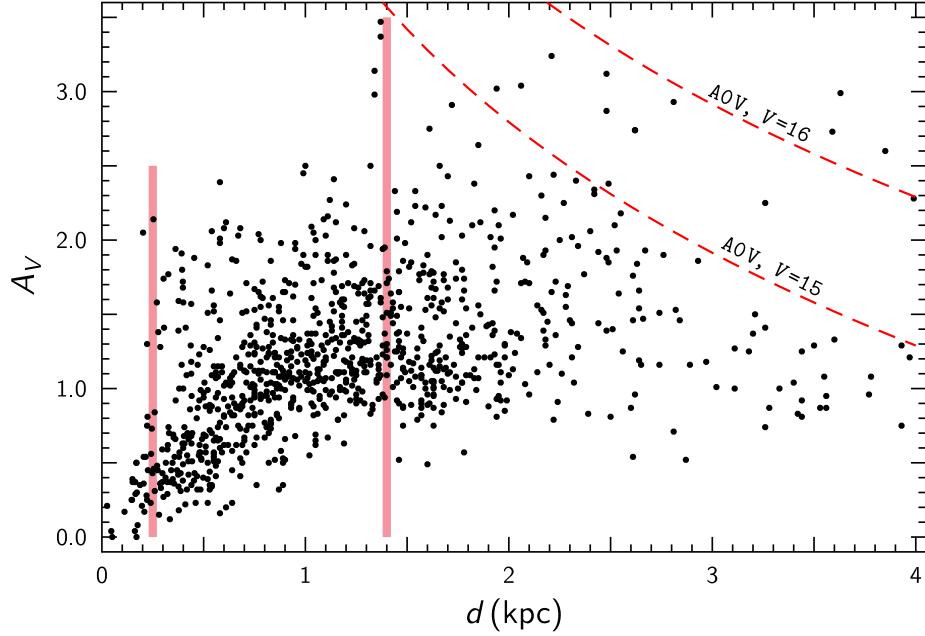

Figure 3.7.: Extinction versus distance for the investigated King 7 area up to $d = 4$ kpc for 982 stars with reliable two-dimensional classification. The two broken red curves show the limiting magnitude effect for A0 V stars at $V = 15$ and 16 mag. The two vertical solid red lines designate the positions of dust concentrations at 250 pc in the Local arm and at 1.4 kpc close to the Perseus arm.

3.3. Distance to the dust clouds in the vicinity of the star cluster King 7

For the analysis of the interstellar extinction in the area we selected only the stars with reliable two-dimensional classification. The stars, which gave either large deviations from the luminosity sequences of normal stars in the reddening-free Q, Q diagrams or large σQ values in the COMPAR classification method (> 0.03 mag), were rejected. These stars can be either peculiar (metal-deficient or emission-line stars) or unresolved binaries. Some of the rejected stars were too faint in the ultraviolet passbands (especially in U) to be measured with sufficient accuracy.

For 982 stars with reliable spectral and luminosity classes, color excesses E_{Y-V} were calculated as the differences between the observed and intrinsic color indices taken from Straižys (1992). The interstellar extinctions A_V and distances d (in pc) were calculated with the equations (3.2) and (3.3). The coefficient in Eq. (3.2) corresponds to the normal interstellar extinction law. Normality of the law is based on the analysis of color excesses of B and A stars in the general direction of the Camelopardalis clouds (Zdanavičius et al. 2002b) and in the TGU H994 P1 area (Straižys et al. 2016a).

The plot A_V vs. d for 982 stars in the whole 1.5 deg^2 area with distances up to 4 kpc is shown in Fig. 3.7. Most of the stars show approximately exponential rise of the extinction up to about ~ 1.5 mag at 1.5 kpc. At larger distances the number of stars considerably decreases due to limiting magnitude effect. This effect can be estimated by the two broken curves shown in Fig. 3.7, corresponding to

A0 V stars with $V = 15$ and 16 mag. Above these curves only a few stars of early-types are seen. The same curves are also valid for K-type giants which have similar absolute magnitudes as A0 V stars. For A-F-G-K stars of the main-sequence belt, as well as for G5-K subgiants these curves are located lower and closer to the Sun.

A steep rise of the extinction is seen at about 250 pc which can be related with a concentration of dust clouds in the Local arm. This means that in the direction of King 7 the nearest to the Sun dust clouds are farther than in the surrounding areas, which we investigated in Straizys et al. (2016a), (the dark cloud TGU H994 P1 area) and in Straizys et al. (2016b) (the H II region Sh2-205 area). In that two areas we have found that the Camelopardalis dust clouds begin at 130–140 pc.

The next jump of heavily reddened stars in Fig. 3.7 is evident at 1.3–1.4 kpc, where our sightline enters the Perseus spiral arm in the direction of the Galactic longitude $\ell \sim 150^\circ$. However, due to the limiting magnitude effect, stars with the extinctions higher than $A_V = 3.5$ mag were not observed.

Chapter 4

Identification of Young Stellar Objects (YSOs)

YSOs in the investigated areas were identified using the Koenig & Leisawitz (2014) classification scheme which applies combining of the WISE ($W1$, $W2$, $W3$ and $W4$) and 2MASS (J , H , and K_s) near- and mid-infrared colors. The AllWISE catalog (Cutri et al. 2014) was used. First, the cuts in signal-to-noise versus space was applied to suppress the fake component. The signal-to-noise ($Wsnr$) and reduced chi-squared ($Wrchi2$) parameters given in the AllWISE photometric catalog for each Wise filter give a strong discriminating power between real and fake point sources. Then the objects that meet the requirements for star forming galaxies and Active Galactic Nuclei (AGNs) were removed. Then we searched for YSO candidates using criteria of Koenig & Leisawitz (2014).

4.1. YSOs in the TGU H 994 P1 area

The clouds in the investigated area do not show active star formation. Radio observations in molecular lines reveal a number of cool gas cores of the subparsec sizes, which might be prestellar clumps. However, stellar YSOs in the area are quite scarce. In the investigated area only 2 YSOs were found and all belong to Class II (Table 4.1).

In Fig. 4.1, only a few stars are located in the region of possible T Tauri stars. Among them, the most reliable candidate is 2MASS J04251408+5456524 at $J-H = 1.53$ and $H-K_s = 0.97$. Two more possible YSOs, 2MASS J04241953+5453594 and J04262976+5450399, are revealed by the K_s-W1 vs. $W1-W2$ diagram. These three stars all are seen in the direction of LDN 1400. A few stars located in Fig. 4.1 above the intrinsic T Tauri line (Meyer et al. 1997)) with $J-H = 0.8-1.1$ and $H-K_s = 0.4-0.6$ are candidates to be YSOs of class III (Weak-line T Tauri star (WTTS)). These stars cannot be normal M dwarfs reddened by interstellar dust since in this case their distances are unrealistically small (50–80 pc). Part of them can be binaries whose reddening is caused by a cooler secondary component.

Table 4.1.: YSOs identified in the TGU H994 P1 area

No.	ALLWISE No.	$W1-W2$ mag	$W2-W3$ mag	J mag	$H-K_s$ mag	K_s-W1 mag	Type
1	J042514.08+545652.3	0.656	0.707	12.568	0.976	0.577	YSO2
2	J042629.77+545039.9	0.565	1.891	13.736	0.395	0.415	YSO2

4.2. YSOs in the Sh2-205 area

In the investigated area we found 88 YSOs listed in Table 4.2, among them 25 stars belong to Class I and 63 to class II. Their surface distribution, shown in Fig. 4.2, exhibits strong clustering into the dust clouds seen in the dust map by Schlegel et al. (1998). Only a few objects are scattered around the dark clouds. The largest number of YSOs is concentrated in the dust clump P7 and the infrared cluster FSR 655 with the coordinates $\alpha(2000) = 03^{\text{h}}56^{\text{m}}14^{\text{s}}$, $\delta(2000) = +53^{\circ}51'54''$ (Froebrich et al. 2007). Three of these YSOs were identified earlier by Straižys & Laugalys (2007b), about 16 by Romero & Cappa (2009) using the 2MASS, MSX and IRAS surveys.

A compact group of five YSOs is located at $\alpha(2000) = 03^{\text{h}}54^{\text{m}}56^{\text{s}}$, $\delta(2000) = +53^{\circ}45'$. Probably, these stars are members of a small heavily reddened cluster with an angular diameter of 2.0–2.5 arcmin. Hereafter we will call this possible cluster as SCB 1. Within it about 30 stars down to $K_s \approx 15$ mag can be counted (Fig. 4.3). The extinction of stars in this cluster should originate in the local dust layer at 130–300 pc and the dust cloud TGU H942 P7. The cluster is located almost at the center of the Dobashi 4040 cloud (Dobashi 2011). From a statistical analysis of $J-H$ and $H-K_s$ colors in this cloud, Dobashi (2011) finds its average extinction $A_V = 6.85$ mag. For the extinction across the Galaxy, the dust map calibrated by Schlafly & Finkbeiner (2011)¹ in this direction gives a value of $A_V = 7.28$ mag.

4.3. YSOs in the King 7 area

In the investigated area we found 28 YSOs listed in Table 4.3, among them two stars belong to Class I and 26 to class II. One of these YSOs was identified by Straižys & Laugalys (2007b), one by Straižys & Kazlauskas (2010) and one by Romero & Cappa (2009) using the 2MASS, MSX and IRAS surveys. YSOs surface distribution exhibits no strong clustering into the dust clouds seen in the dust map by Schlegel et al. (1998), but two concentrations of YSOs could be identified in the investigated area. The first contains 8 YSOs and is situated in the vicinity surrounded by reflection nebulae GN 03.56.2, GM1-34, H II region BFS 33, IRAS03561+5124 source and IR cluster Camargo 440. The second clustering contains 4 YSOs and is surrounded by dark clouds TGU H989 P2 and Dobashi 4059. The dense core PLCHECC G149.52-01.23 and IRAS03528+5142 source are also situated in that area.

We crossmached our identified YSOs with our photometric catalogue (Zdanavičius et al. 2010) and found that YSO No. 1 (Table 4.3) is only 0.45 arcsec apart from the star No. 230, classified as b2.5 III star located at 4.91 kpc. Corbally & Straižys (2009) classified this star (Gahm 11 in their list), also known as EM* GGA 271, as F0e and this clasification is given in the Simbad database. We also crosmached our YSO list with the objects that are available in the Simbad database and found that positions of YSOs No 1, 5, 16, and 21 (Table 4.3) with accuracy better than 1'', are the same as EM* GGA 271 (emision line star), V 929 Per (long period variable), V939 Per (long period variable), and V942 Per (RR Lyr), respectively.

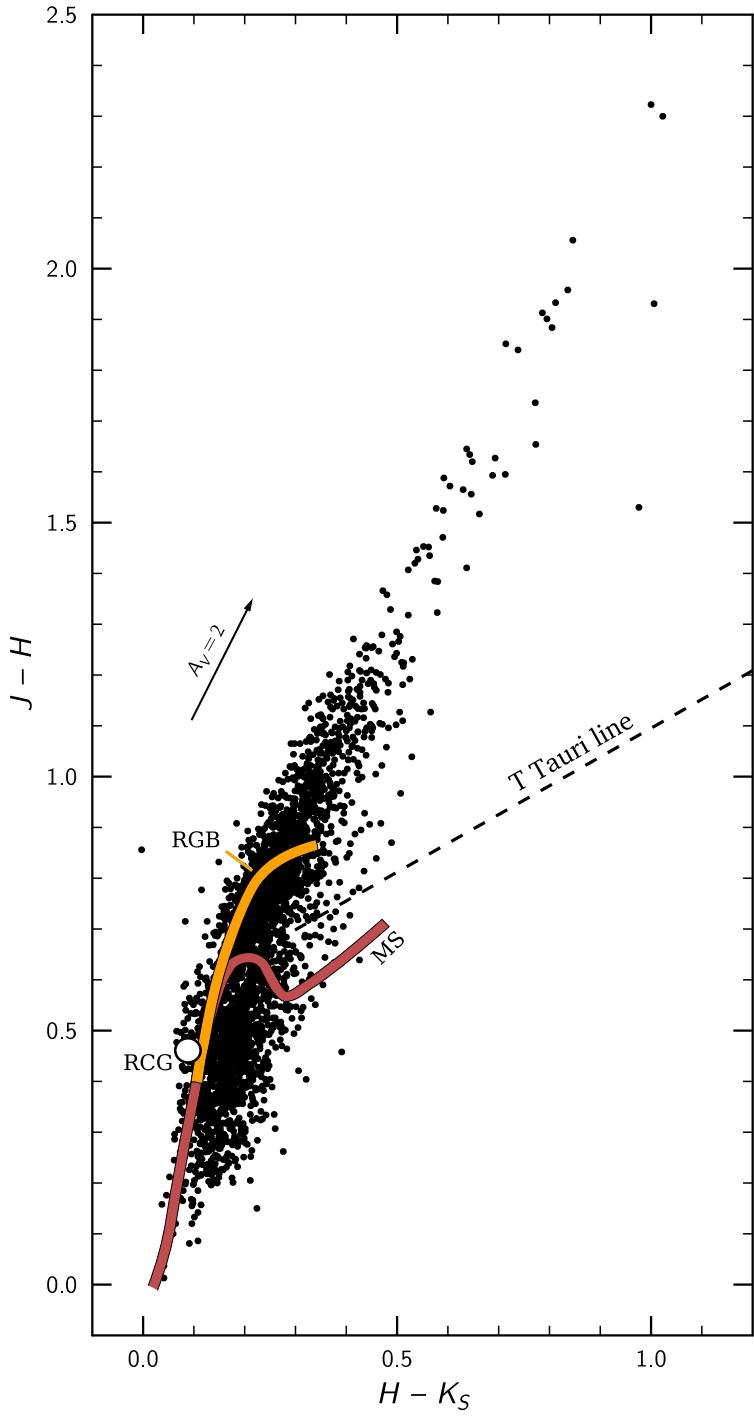

Figure 4.1.: The $J - H$ vs. $H - K_s$ diagram for 3230 stars in investigated TGU H994 P1 area. Only stars with the magnitude errors ≤ 0.03 mag are plotted. The main sequence (MS, brown line), the red giant branch (RGB, orange line), the intrinsic locus of red clump giants (RCG, red circle), the intrinsic line of T Tauri stars (broken line) and the reddening line for $A_V = 2$ mag are shown.

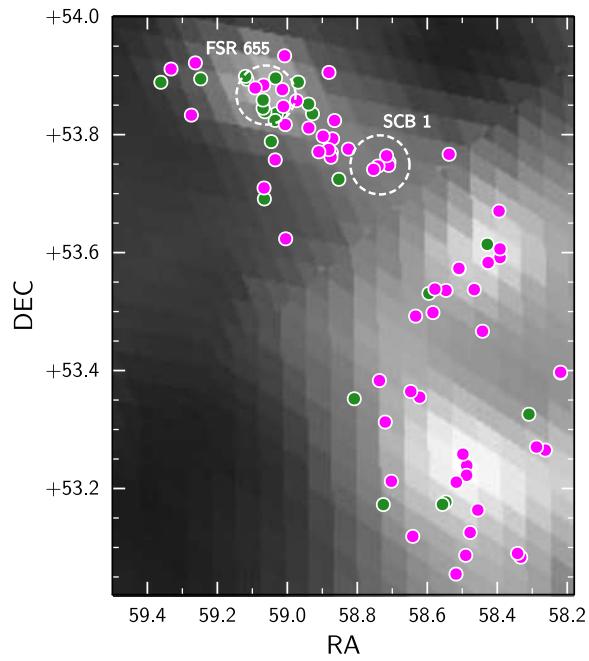

Figure 4.2.: Surface distribution of YSOs of types I (green circles) and II (red circles) in the Sh2-205 area. Dust map from Schlegel et al. (1998) is shown in the background. The cluster FSR 655 and the new possible infrared cluster SCB 1 are marked with broken circles.

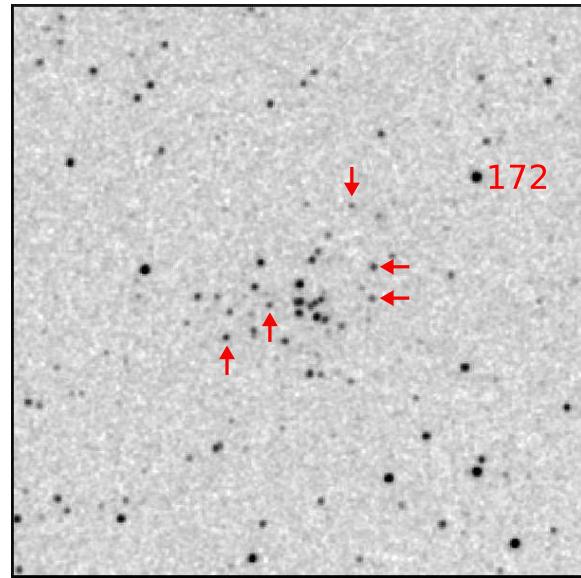

Figure 4.3.: New possible infrared cluster SCB 1 at $\alpha(2000) = 03^{\text{h}}54^{\text{m}}56^{\text{s}}$, $\delta(2000) = +53^{\circ}45'$ identified in the investigated area. The image of $0.1 \times 0.1 \text{ deg}^2$ size in the 2MASS filter K_s is taken from the SkyView Virtual Observatory. The five YSOs are marked with arrows. The star 172 is present in the Table A.3 ($V = 12.53$, A5 V).

Chapter 5

Results and discussion

5.1. Dark cloud TGU H994 P1 area

The distance to the cloud TGU H994 P1 estimated in Sect. 3.3 is based on the assumption that the reddened star No. 428 (k1 V) has appeared at 111 pc owing to a negative 3σ distance error. Then the true distance of this star should be at 140 pc, where the cloud causing its reddening is located. This result is also supported by a few stars with low extinction and distances up to 180 pc. If these stars are located in front of the cloud, i.e. at 140 pc, they could be shifted to their apparent positions because of positive 3σ distance errors. A distance of 140 pc is in agreement with the distance to the complex of the Taurus dark clouds located on the opposite side of the Milky Way disk. On the other hand, the Camelopardalis complex of dark clouds can be very deep along the sightline, as is the case with the Taurus complex, which has a depth of up to 50 pc or more, determined from radio interferometry of young stellar objects (Loinard et al. 2011) and from interstellar line strengths (Welsh et al. 2010; Lallement et al. 2014) combined with the Hipparcos parallaxes.

The investigated area is located at $b = \sim 4^\circ$, and this means that with increasing distance our sightline recedes from the Galactic plane: the height above the plane is 70 pc at 1 kpc, 140 pc at 2 kpc, 280 pc at 4 kpc, etc. The expected extinction rise due to the diffuse dust layer near the plane (the Parenago law, Fig. 3.2) at $d > 1$ kpc should be rather low. Therefore, the extinction level at large distances must be defined mainly by the cloud with an additional small component caused by the diffuse dust layer. This is confirmed by the extinction versus distance plot in Fig. 3.3, where the results of deep classification of stars up to ~ 19 mag are shown. The minimum extinction in the most transparent directions remains at about 1.5–2 mag, and the maximum extinction in the directions where our sightline crosses peripheries of the dense clouds is between 4 and 5 mag. At the distances of the Perseus Arm and the Outer Arm, our sightline is about 100–140 pc and 350 pc above the plain. Thus, the influence of dust content in these two arms is not detectable.

Fig. 5.1 shows that RCGs exhibit more or less the same minimum extinction level close to $A_V = 1.5$ –2 found for the other stars classified in the Vilnius system (Figs. 3.2 and 3.3). However, the maximum extinction is larger by about 1.5–2.5 mag, reaching about 6.5 mag in the dark filaments and around them.

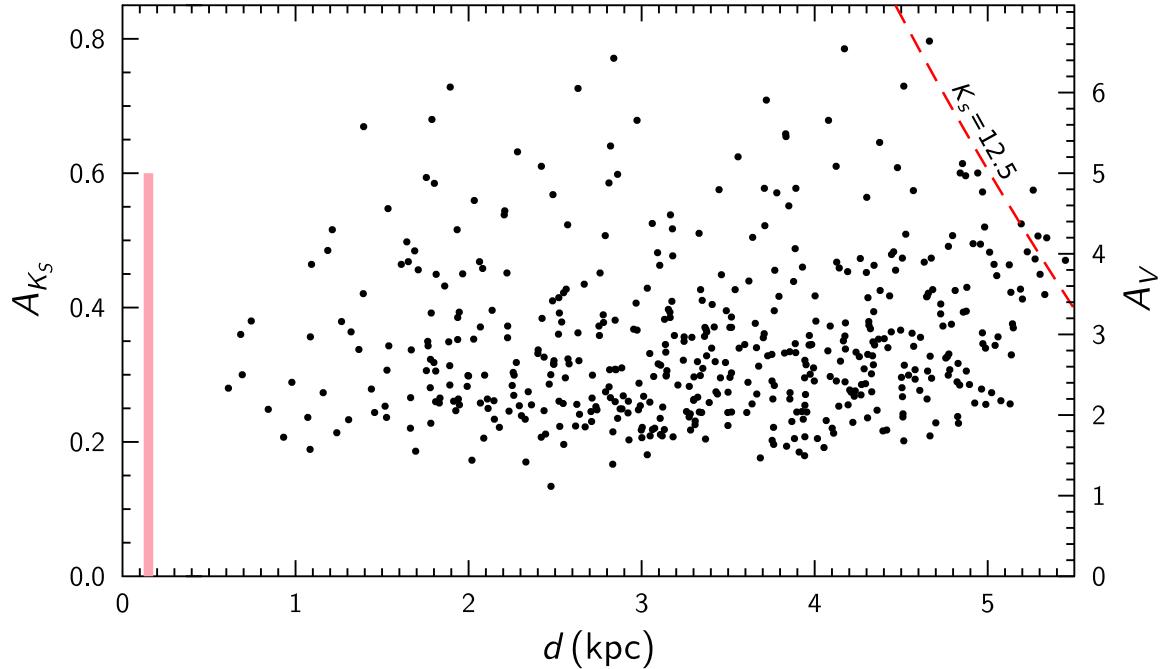

Figure 5.1.: The extinction A_{K_s} vs. distance in the TGU H 994 area for the RCGs identified combining the 2MASS and WISE magnitudes. The vertical line designates the accepted position of the cloud TGU H994 P1 at 140 pc. The red broken curve designates RCGs at the limiting magnitude $K_s = 12.5$ mag.

5.2. H II region Sh2-205 area

The investigated area is rather non-uniform with respect to distribution of interstellar extinction in the Local Arm. The largest extinction is found in the directions of the clumps P7 and P8, including the chain of the Dobashi (2011) clouds with numbers 4040–4051. However, differences in the extinction become evident only at distances exceeding ~ 400 pc. At smaller distances the whole area is covered by the nearest clouds more or less uniformly. The nearest cloud layer begins at a distance of 130 ± 10 pc, where the extinction A_V steeply rises from 0.3 to 1.8 mag (Fig. 3.4). Between 200 and 400 pc the extinction continues to rise up to 2.7 mag. Another jump of extinction up to ~ 4 mag is possible at a distance of 500–600 pc, it is better visible in Fig. 3.6. The space between the Local and Perseus arms (1–1.5 kpc) should be free of dust. This, however, seems to be confirmed only by RCGs in Fig. 5.2 since the extinction in Figs. 3.5 and 3.6 in this distance range is affected by the limiting magnitude effect and the scatter of stars because of classification and distance errors. For some RCGs, located within and behind the Perseus Arm, the extinction A_V becomes as large as ~ 8 mag (Fig. 5.2). However, these stars lie outside the densest parts of the clouds. Within the clouds the extinction can be estimated by the dust maps by Schlegel et al. (1998) based on the 100 μm dust emission, calibrated by Schlafly & Finkbeiner (2011), see the NED database. These maps give the values of $A_V \sim 9.3$ mag in the center of P7 (or Dobashi 4043), 15.0 mag between Sh2-205 and the clump P8, and 13.4 mag in the dust cloud Dobashi 4042 above Sh2-205 (see Fig. 1.3).

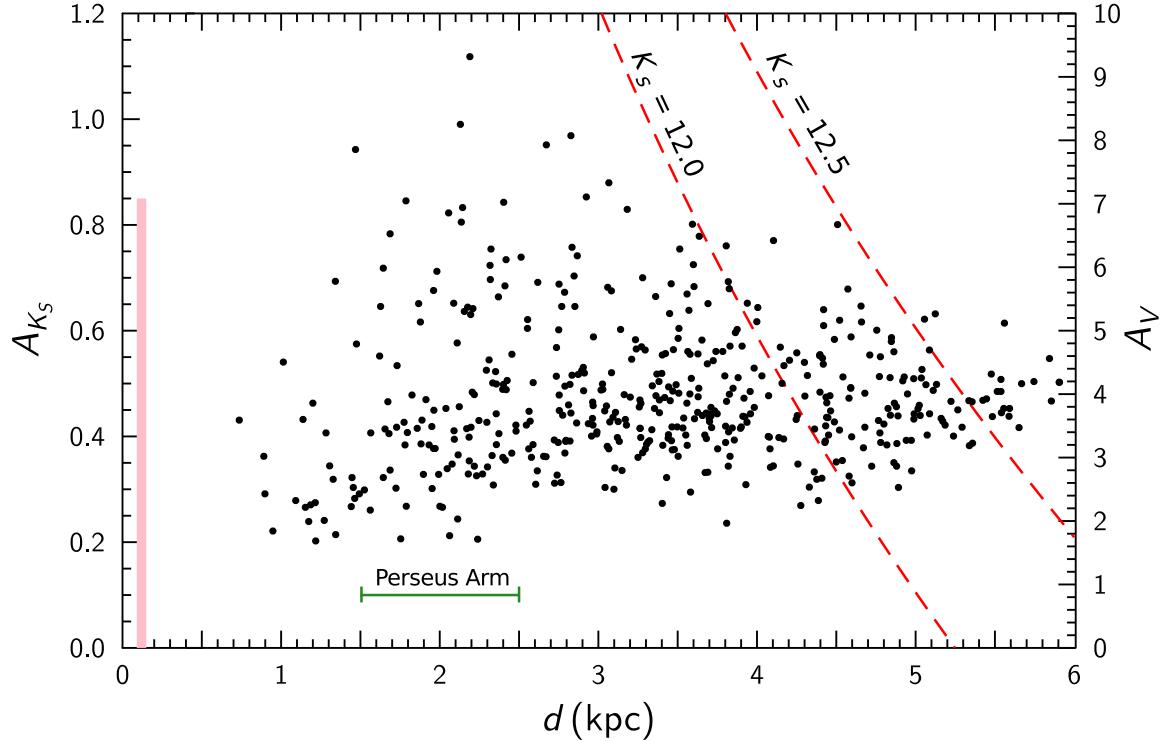

Figure 5.2.: The extinction A_{K_s} vs. distance in the Sh2-205 area for 662 RCGs identified combining the 2MASS and WISE magnitudes. The vertical line designates the accepted position of the nearest layer of dust at 130 pc. The two broken curves designate RCGs at the limiting magnitudes $K_s = 12$ and 12.5. The shown distance of the Perseus Arm is the average value from Reid et al. (2014) and Vallée (2014).

The lowest values of A_V at distances > 1 kpc, determined from Figs. 3.5, 3.6 and 5.2, are close to 1.5–2.0 mag. Probably in these directions distant stars are observed through semi-transparent windows between clouds.

The extinction distribution in the area can be compared with distribution of molecular clouds applying radio observations of CO lines from Dame et al. (2001). In this case, instead of the distance, we may use radial velocities of molecular clouds which are functions of the distance due to Galactic rotation. The positions of CO clouds within our area, shown in Straižys & Laugalys (2007a) and Straižys & Laugalys (2008), approximately coincide with the largest dust concentrations. The analysis of the Dame et al. (2001) data shows that the local standard of rest (LSR) radial velocities of CO clouds P7 and P8 mostly concentrate in the three intervals with maxima at -2.5 km/s, ~ -6 km/s and ~ -34 km/s. The first two intervals correspond to the Local Arm, and the third one to the Perseus Arm. To estimate galactocentric distances R to CO clouds we applied the equation of kinematic distances:

$$R = R_0 \sin (\ell) \frac{V_R}{V + V_0 \sin (\ell)}, \quad (5.1)$$

where V is its measured radial velocity, V_R is the accepted galactocentric orbital velocity of the cloud (taken from the Galactic rotation curve), R_0 is the galactocentric radius of the solar orbit, V_0 is the solar orbital velocity, ℓ is the Galactic longitude (in our case 148.3°). In the calculations we

took the values of R_0 and V_0 from Bovy et al. (2012) and Reid et al. (2014), in both cases the flat Galactic rotation curve was accepted.

Heliocentric distances to the clouds d were calculated from R with the equation

$$d = \frac{(R - R_0)}{\cos(180 - \ell)}. \quad (5.2)$$

In the case of the Bovy et al. (2012) parameters, $R_0 = 8.10$ kpc and $V_0 = 218$ km/s, we obtain $d = 208$ pc at $V_r = -2.5$ km/s and $d = 520$ pc at $V_r = -6$ km/s. In the case of the Reid et al. (2014) parameters, $R_0 = 8.34$ kpc and $V_0 = 240$ km/s, the corresponding distances d are 196 pc and 485 pc. Thus, the first layer of CO clouds with the kinematic distance ~ 200 pc can be related to the local dust layer between 130 and 300 pc seen in Figs. 3.5 and 3.6. The second CO layer with the kinematic distance ~ 500 pc can correspond to the jump of extinction at 500–600 pc described in Chapter 3.2. Since the infrared cluster FSR 655 and the new cluster SCB 1, identified in this paper, seem to be related with the chain of dust clouds P7, Dobashi 4042 and P8, as well as with the concentration of YSOs in these clouds, their distances should be similar, probably within 500–600 pc.

We do not give any kinematic distance corresponding to the velocity -34 km/s, since in the Perseus arm CO clouds and star-forming regions exhibit considerable departures from the circular rotation due to streaming and expanding motions (Sitnik 2003; Vallée 2008; Choi et al. 2014; Foster & Brunt 2015).

The distance to the Sh2-205 nebula is of a special interest. Its ionized areas seem to be tangled with the dust clump P8, so there is an impression that both the nebula and the dust cloud are at the same distance. Trying to verify this, we collected from the literature all known determinations of radial velocities of the nebula and the adjacent HI and CO clouds to calculate their kinematic distances. Unfortunately, the results described in the next paragraph are contradictory.

Probably the first value of radial velocity of Sh2-205, -25.8 km/s, corresponding to its H α line, was published by Blitz et al. (1982). However, in the same paper a note is given which says that there is another H α line at -7 km/s, which is considered as belonging to the foreground. Also for the H α line, Fich et al. (1990) find a value of -16.8 km/s. Fich & Blitz (1984) for the associated CO cloud find a value of -25.8 km/s. Foster & MacWilliams (2006) for the associated HI cloud find -6.0 km/s. Foster & Brunt (2015) find -6.48 km/s for CO and -14.24 km/s for HI. The last value of velocity for CO is very close to the middle value obtained from the Dame et al. (2001) CO data above in this section. The values close to -20 km/s are more appropriate to the Perseus Arm. As the explanation of such differences in the measured radial velocities, we may suggest peculiar motions at different positions of the clouds. In some cases, the velocities could be measured for the clouds of the Perseus Arm seen through translucent clouds in the vicinity of Sh2-205. A special investigation of the velocity field in the vicinity of this nebula would be helpful.

The possible ionizing stars of the Sh2-205 nebula and its southern extension are: HD 24431, (O9 from III to V), HD 24094 (CY Cam, B1 III to V), HD 23675 (B0 III), and ALS 7793 (B1 V). All of them are located within 1° from Sh2-205. The H α map from Finkbeiner (2003), available at

the SkyView Virtual Observatory, shows that the first two of these stars are surrounded by dense H II regions. The northern region around CY Cam is the Sh2-205 nebula; it is located at the right-hand edge of the area investigated in the present paper. The southern region around HD 24431 is located about 0.5° south from the lower edge of our area. The IRAS images and the composite WISE map¹ show that in 20–60 μm maps CY Cam is surrounded by a double lens-like $4' \times 7'$ spot of emission which probably originates in warm dust grains. At 100 μm this emission is absent. At an angular distance of $12' - 15'$ this lens is surrounded by an envelope of rectangular shape with emission originating in cold dust grains (IRAS 100 μm map) and the molecules of polycyclic aromatic hydrocarbons (PAHs, WISE 12 μm map). In the vicinity of ALS 7793, both the dust and PAH emissions are also present. The star HD 23675 does not exhibit its own H II region, as well as emission from dust and PAH molecules.

Photometric distance to CY Cam is uncertain because of its doubtful luminosity class and a possibility that the star is close binary. If the star is of spectral class B1 V with $M_V = -3.4$ mag, we get its extinction $A_V = 2.25$ mag and the distance $d = 780$ pc. If the star is a binary with two identical components, then its distance should be increased by a factor of 1.41, i.e. it becomes about 1.1 kpc. This would mean that the star, as well as the S2-205 nebula, are much farther from the Sun than the chain of dust clouds scattered in its apparent vicinity.

5.3. Star cluster King 7 area

Fig. 5.3 shows the A_{K_s} vs. d plot in the investigated area for 527 RCGs up to 6 kpc. The right-hand y-axis shows the extinctions transformed to the A_V scale with the equation

$$A_V = 8.3 A_{K_s}, \quad (5.3)$$

The two curves in the right part of Fig. 5.3 show the limiting magnitude effect for RCGs of magnitudes $K_s = 12.5$ and 12.0. The accuracy of the extinction and distance can be estimated with the equations $\sigma(A_{K_s}) = \pm 0.115 A_{K_s}$ and $\sigma(d) = \pm 0.042 d$ (Straižys et al. 2015).

The number of RCGs with $d < 1$ kpc is rather small because of a few reasons: (1) the decrease of space volume, (2) the exclusion of stars with $H-K_s < 0.10$ (see the previous paragraph) and (3) the saturation of images in the $W2$ passband. However, the steep extinction rise at 800–900 pc seems to be real, since it repeats a similar extinction jump in Fig. 3.7, but to much higher extinction values. Most of identified RCGs are located in the Perseus Arm (1.5–2.5 kpc from the Sun) and behind it. In the Perseus Arm there is slight increase of the extinction. The maximum value of $A_V = 6.7$ mag is reached at 3 kpc. Beyond the far edge of the Perseus Arm the extinction ceases to grow, remaining at the average value of ~ 4 mag.

Figure 5.4 shows the surface distribution of dust across the Galaxy in the $1.5^\circ \times 1.5^\circ$ area centered on King 7 according to Schlegel et al. (1998). Their atlas has been plotted using the 100 μm dust

¹ WISE Multimedia Gallery Images,
wise.ssl.berkeley.edu/gallery_images.html

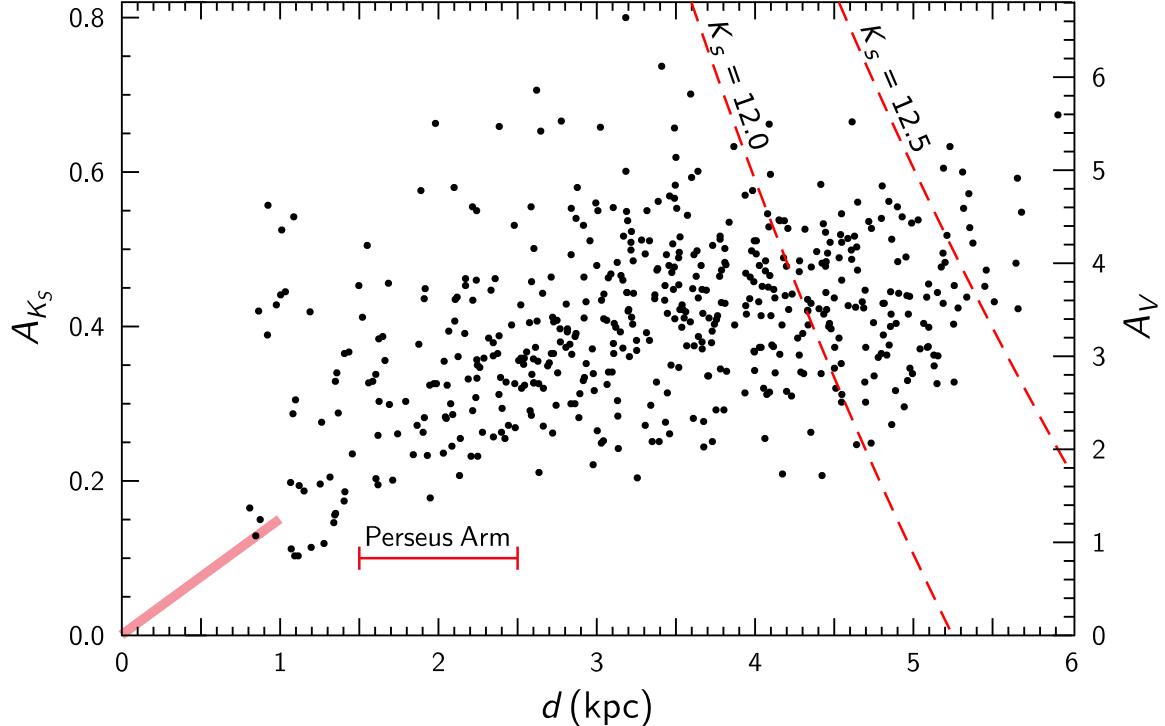

Figure 5.3.: Dependence of the extinction on distance in the King 7 area for 527 RCGs up to $d = 6$ kpc. The straight line from the origin of coordinates up to $(A_{K_s}, d) = (0.15, 1.0)$ shows the average extinction run from Fig. 3.7. The two broken curves show the limiting magnitude effect for RCGs at $K_s = 12$ and 12.5 mag. The horizontal bar shows the expected position of the Perseus arm.

emission observed by the IRAS and COBE space missions with a resolution of about $2.4'$ per pixel. Dust distribution with much higher resolution, $\sim 6''$, can be estimated applying the W3 passband of the WISE mission which covers the wavelength range $8\text{--}16 \mu\text{m}$ (Wright et al. 2010). This range includes some strong emission bands at $8.6, 11.3$ and $12.7 \mu\text{m}$ and the underlying blended emission plateaus belonging to molecules of polycyclic aromatic hydrocarbons (PAHs). These molecules usually are well mixed with dust, and the intensity of their emission can be accepted as an indicator of interstellar extinction (Giard et al. 1994; Whittet 2003). Fig. 5.5 shows the W3 map for the same King 7 area. It is evident that large-scale distributions of PAHs in the W3 passband and dust emission at $100 \mu\text{m}$ (Fig. 5.4) are very similar. However, due to higher resolution, the W3 map shows much more details.

Figs 5.4 and 5.5 show that the most transparent directions in the investigated area are in both upper corners and along the right border of the area. The highest concentration of dust is seen in the lower left corner of the area, in the direction of the emission nebula Sh2-206. However, surface distributions of the dust and PAH emission are of little use for the estimation of distances to the clouds which are expected to cover the Local and Perseus arms.

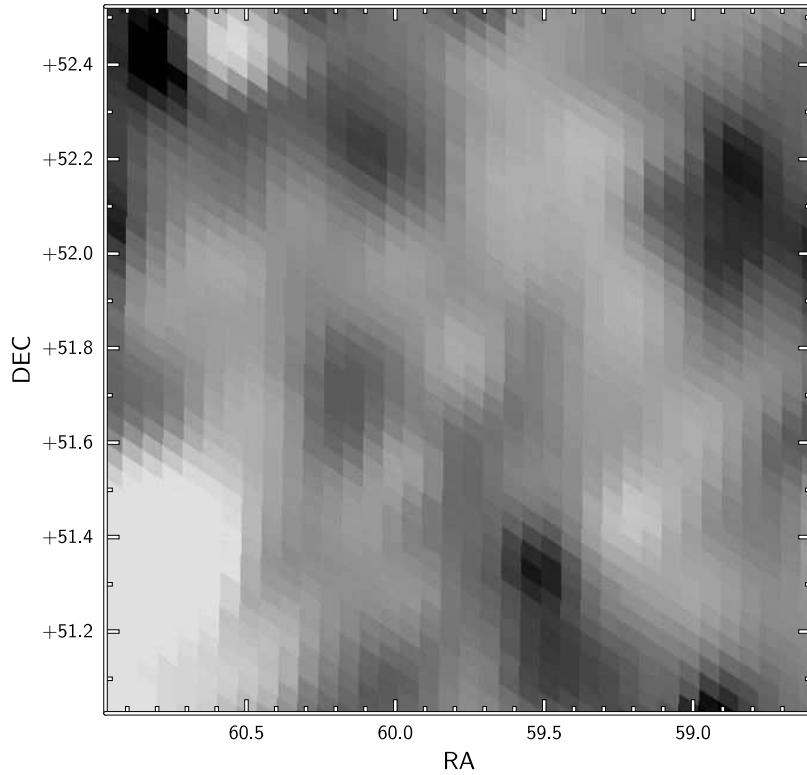

Figure 5.4.: Dust map based on the emission at 100 μm measured by the IRAS and COBE space missions (Schlegel et al. 1998). The area is of the $1.5^\circ \times 1.5^\circ$ size centered on the King 7 cluster.

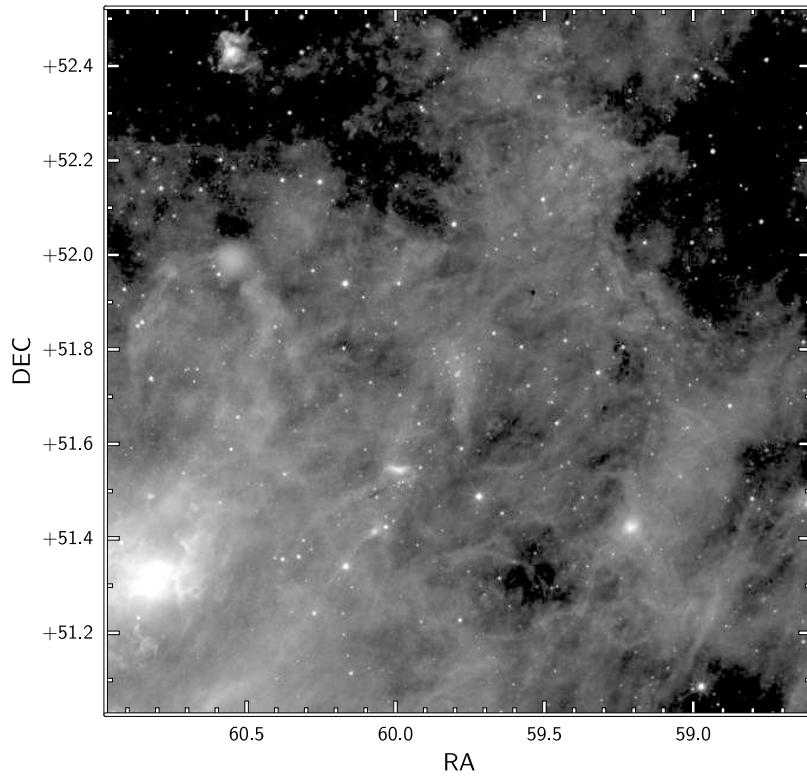

Figure 5.5.: The WISE map in the W3 (12 μm) passband of the same area as in Fig. 5.4

Conclusions

1. Interstellar extinction is investigated in a 1.5 square degree area in the vicinity of the dark cloud TGU H 994 P1 at $\alpha(2000) = 04^{\text{h}}25^{\text{m}}30^{\text{s}}$, $\delta(2000) = +54^{\circ}55'00''$. Based on photometric classification of 584 stars down to $V = 17$ mag and of 447 stars down to $V = 20$ mag, the distance to the dust cloud TGU H994 clump P1 is estimated to be 140^{+36}_{-31} pc.
2. Interstellar extinction is investigated in a 1.5 square degree area in the vicinity of the H II region Sh2-205 at $\alpha(2000) = 03^{\text{h}}57^{\text{m}}00^{\text{s}}$, $\delta(2000) = +53^{\circ}40'00''$ (in the direction of two clumps (P7 and P8) of the dust cloud TGU H942). Based on photometric classification of 628 stars down to $V=17$ mag and of 238 stars down to $V = 19.5$ mag, it was determined, that the dust concentrates at least in two layers at 130^{+35}_{-27} pc and 500–600 pc.
3. Interstellar extinction is investigated in a 1.5 square degree area in the direction of the open cluster King 7 at $\alpha(2000) = 03^{\text{h}}59^{\text{m}}00^{\text{s}}$, $\delta(2000) = +51^{\circ}48'00''$. Based on photometric classification of 982 stars down to $V = 16$ mag, it was determined that the dust in the investigated area concentrates at least in two layers at 250^{+65}_{-52} pc and 1.3–1.5 kpc.
4. Active star formation was determined in the H II region Sh2-205 and cluster King 7 areas.
5. A new infrared star cluster at $\alpha(2000) = 03^{\text{h}}54^{\text{m}}56^{\text{s}}$, $\delta(2000) = +53^{\circ}45'00''$ was found and named SCB 1.

Acknowledgements

Undertaking this PhD has been a truly life-changing experience for me and it would not have been possible to do without the support and guidance that I received from many people.

I would like to first say a very big thank you to my supervisor Justas Zdanavičius and scientific consultant Vytautas Straižys for all the support and encouragement they gave to me during the long years of my doctoral studies. Without their guidance and constant feedback this PhD would not have been achievable.

During all these years I felt a constructive support and share of knowledge from Kazimieras Zdanavičius who is an expert in stellar classification.

I would like to express my sincere thanks to everybody who assisted me in my doctorate studies and in the preparation of materials for the doctoral thesis.

The greatest thanks to my family and especially to my parents for their understanding, support and patience during long years of my studies.

Great thanks to Gražina Tautvaišienė, Algirdas Kazlauskas, Kazimieras Černis, Marius Maskoliūnas for their support and advices during my doctoral studies. I would like to thank Oleg Malkov and Vladas Vansevičius, the reviewers of my thesis, for their useful comments and advices. I would like to express my thanks to Richard P. Boyle and all the staff of the Vatican Observatory for provided ability to observe with VATT and nice hosting during my visits in USA.

I am very grateful to all the authorities and staff of the Institute of Theoretical Physics and Astronomy and to all staff members of the Molėtai Observatory for good working atmosphere and a comprehensive support.

I also thank to the colleagues of the Ministry of Education and Science of the Republic of Lithuania for my support.

In this study I have used the Simbad, 2MASS, Sky View and WISE databases, which are also acknowledged.

Appendix A

Photometry and classification of stars

A.1. Maksutov photometry and classification of stars in the TGU H994 P1 area

Table A.1 Results of photometry and classification of stars in the TGU H994 P1 area. The stars with two asterisks in the last column were not classified in two dimensions since their images are asymmetrical, i.e., these stars are double or multiple. The components of some of them are seen separately, but they are closer than 7".

A.2. VATT photometry and classification of stars in the TGU H994 P1 area

Table A.2.: The data catalog of stars in the three areas of TGU H994 P1 measured in the Vilnius seven-colour system from the VATT CCD exposures. The stars are numbered starting from 1001 to avoid confusion with the Maksutov catalog A.1. The running numbers, coordinates, V magnitudes, six color indices, photometric spectral types interstellar extinctions and distances are given. The stars with two asterisks in the last column have close neighbours or show asymmetrical images in the SkyView DSS atlas and/or VATT CCD exposures.

A.3. Maksutov photometry and classification of stars in the Sh2-205 area

Table A.3. Results of Maksutov photometry and classification of stars in the Sh2-205 area. The stars with two asterisks in the last column were not classified in two dimensions since their images are asymmetrical, i.e., these stars are double or multiple. The components of some of them are seen separately but they are closer than 7''.

A.4. VATT photometry and classification of stars in the Sh2-205 area

Table A.4.: The data catalog of stars in the $12' \times 12'$ area in the vicinity of the nebula Sh2-205 measured in the Vilnius seven-colour system from the VATT CCD exposures. The stars are numbered starting from 1001 to avoid confusion with the Maksutov catalog A.3. The running numbers, coordinates, V magnitudes, six color indices, photometric spectral types, interstellar extinctions and distances are given. The stars with two asterisks in the last column are unresolved binaries.
