INVESTIGATION OF STAR FORMING REGIONS IN CEPHEUS

Doctoral Dissertation
Physical Sciences, Physics (02 P)

Vilnius, 2014

Doctoral Dissertation was completed during 2008–2013 at Vilnius University, Institute of Theoretical Physics and Astronomy

Scientific supervisor:

Dr. Justas Zdanavičius (Vilnius University, Institute of Theoretical Physics and Astronomy, Physical sciences, Physics – 02 P)

Scientific advisor:

Habil dr. Kazimieras Zdanavičius (Vilnius University, Institute of Theoretical Physics and Astronomy, Physical sciences, Physics – 02 P)

Introduction

The space between stars contains the interstellar matter in the form of atomic and molecular gas and dust. Most of the interstellar dust form the clouds which are concentrated in the disk of the Galaxy, mostly in spiral arms. Despite their small contribution to the mass of material in interstellar clouds (only about 1 %), dust particles play an important role due to their capability to absorb and scatter the light of stars located behind the clouds. The combined effect of absorption and scattering is called interstellar extinction which is a measure of weakening of star light. Because the dependence of interstellar extinction on wavelength (the interstellar extinction law) the light of stars located behind the dust clouds becomes redder and fainter.

The dust and molecular clouds are the sites of star formation due to gravitational contraction of occasional condensations of the interstellar matter and partly due to shock waves from supernova explosion. The cloud, in which stars younger than 10 Myr are usually called as star-forming region. If hot massive stars are predominantly present in such a region, they are called an OB-associations.

One of the most active star-forming regions is located in the Cepheus constellation, at the Galactic longitudes between 100° and 120°İn this sky region, the band of the Milky Way splits into two branches, with one branch stretching approximately along the Galactic equator and the another branch forming the so-called Cepheus Flare. The latter branch separates from the main Milky Way band in the northern part of the Cygnus constellation and extends, at some angle to the Galactic equator, towards the North Celestial Pole in Ursa Minor. The Cepheus Flare contains a few star forming regions, which have recently been described by Kun et al. (2008) in the Handbook of Star Forming Regions, published by the Astronomical Society of the Pacific. Since these regions are very important to understanding the evolution of the Galaxy, especially its spiral structure, we selected some of these regions for the present photometric investigation. In our investigation we applied the Vilnius seven-color photometric system at the mean wavelengths of its passbands 345, 374, 405, 466, 516, 544 and 656 nm. The system was developed many years ago in

the Vilnius Observatory for the classification of all types of stars, especially in the presence of large and variable interstellar extinction. Using the radiation intensities measured in the passbands of the Vilnius system, it is possible to determine spectral classes (or temperatures), luminosity classes (or absolute magnitudes), and the values of interstellar reddening and extinction. The young stellar objects (YSO) can be also identified adding infrared magnitudes from the published catalogs of the photometric surveys in a number of infrared wavelengths (2MASS, WISE, Spitzer, Akari, etc.) enables a more complete photometric identification of YSOs. All this makes the Vilnius system very useful in the investigation of star forming regions, young open clusters and associations.

The following objects have been selected for the present investigation:

1. The area around the reflection nebula NGC 7023;
2. The area in the nearby dust cloud TGU 619;
3. The area around the reflection nebula and a very young open cluster NGC 7129, which contains also the old open cluster NGC 7142 reddened by the same dust cloud TGU 645 in which NGC 7129 is embedded.

NGC 7023 is a reflection nebula, illuminated by the young massive star HD 200775 and several less luminus stars. It was discovered in 1794 by William Herschel. HD 200775 is a Herbig Be star (also known as V380 Cep and HBC 726) which was studied by Slipher (1918), Altamore et al. (1980), Witt & Cottrel (1980), Witt et al. (1982), Rogers et al. (1995), Laureijs et al. (1996), Fuente et al. (2000), Werner et al. (2004), Pogodin et al. (2004), Alecian et al. (2008), Berne et al. (2008).

In the center of the reflection nebula, Weston (1953) found a small group of variable stars, show Hα line in emission. Approximately two dozens of variable stars in the region were studied by Rosino & Romano (1962). Goodman & Arce (2004) speculate that the young Herbig Ae star PV Cep, located more than 10 pc to the west of the cluster, might have been ejected from NGC 7023 at least 100,000 years ago. HD 200775 is located at the northern edge of an elongated molecular cloud, corresponding to the dark clouds L1167, 1168, 1170, 1171, 1172, 1173 and 1174, most frequently known as L1167/L1174 complex. The cloud complex has been mapped

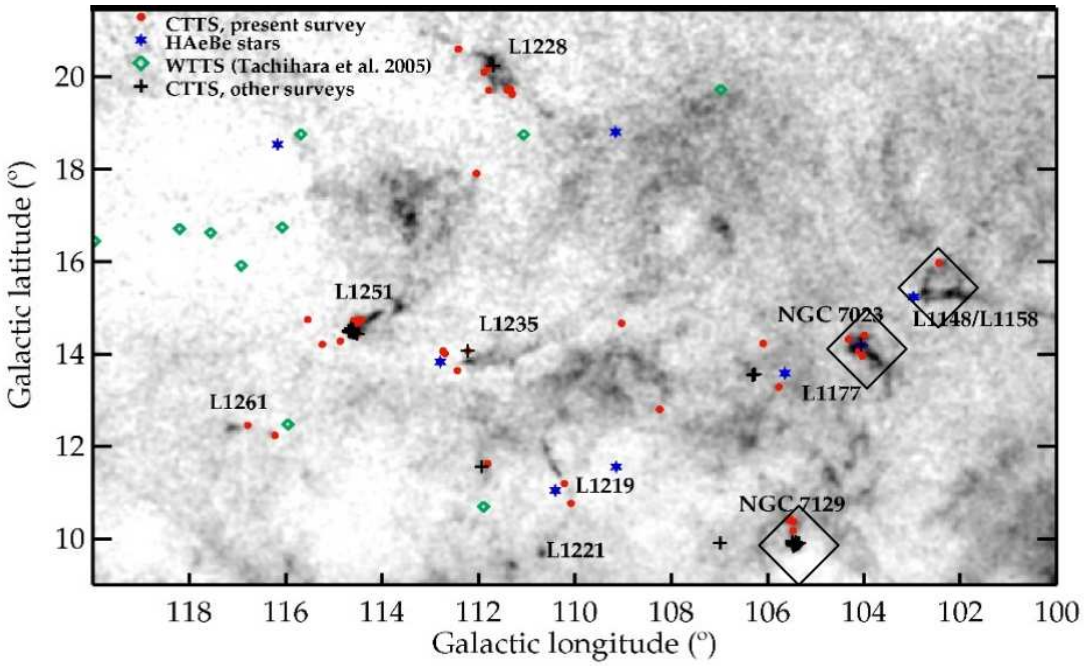

Figure 0.1.: Distribution of pre-main sequence stars in the Cepheus Flare region, taken from Kun et al. (2008), overplotted on the extinction map from the Dobashi et al. (2005). Red dots and black crosses indicate the classical T Tauri stars. Blue star symbols show Herbig Ae/Be stars and green diamonds denote T Tauri stars identified by Tachihara et al. (2005). Three black squares on the right side show the areas investigated in this work. The size of the squares is approximately the same as that of the fields observed with the Maksutov telescope.

in CO by Elmegreen & Elmegreen (1978). They determined the size of the cloud $0.5^\circ \times 1.0^\circ$, or 3.9 pc $\times$ 7.7 pc, and the mass of the molecular hydrogen about 600 $M\odot$.

Close to the star HD 200775, Watt et al. (1986) found a bipolar outflow. The area of the outflow has been mapped by Fuente et al. (1998) according to CO molecular line emission, but they found no evidence for current high-velocity gas. Another molecular outflow, centered on the IRAS source IRAS 21017+6742 was found by Myers et al. (1988). On the K filter image of L1172, Hodapp (1994) found four stars associated with localized nebulosity. Visser, Richter & Chandler (2002) detected three submillimeter sources at the position of IRAS 21017+6742 and L1172 SMM1–SMM3 claiming that there could be a protostar as a source of the outflow.

Dark cloud TGU 619 (Dobashi et al. 2005), corresponding to the Lynds (1962)

clouds LDN 1147, 1148, 1152, 1155, 1157 and 1158, is located about 1.5° west of the reflection nebula NGC 7023. This group of clouds is often referred to as the L1147/1158 complex. The L1157 outfow, associated with the IRAS 20386+6751 source, has been studied in many molecular lines, such as CO (Umemoto et al. 1992; Gueth, Guilloteau & Bachiller 1996; Bachiller & Perez Gutierez 1997; Hirano & Taniguchi 2001) and SiO (Mikami et al. 1992; Zhang et al. 1995; Gueth, Guilloteau & Bachiller 1998; Zhang, Ho & Wright 2000; Bachiller et al. 2001). Many other lines have been identified by Beltran at al. (2001), Benedettini et al. (2007), Arce et al. (2008), making the L1147/1158 complex consisting of a variety of chemical compounds.

Located in the northeastern edge of the dark cloud complex L1147/1158 is the highly variable pre–main sequence star PV Cep. It is a bright IRAS source, and has been detected in radio continuum by Anglada et al. (1992). It illuminates and ionizes reflection nebula known as GM–29 (Gyulbudagian & Magakian 1977) or RNO 125 (Cohen 1980).

The parameters of PV Cep are highly uncertain. Based on the measuremens of narrow-band continuum indices, Cohen et al. (1977) determined its spectral type close to A5.However Magakian & Movsessian (2001) estimated the spectral type G8–K0, based on the spectrum obtained in July 1987, when the star was about 2 magnitudes fainter. The spectral type F, determined by Staude (1986) and Neckel et al. (1987), is also based on the spectral data presented by Cohen et al. (1981).

NGC 7129 lies at the edge of the Cepheus Flare (Kun et al. 2000). This object is the more distant than NGC 7023, or the cloud complex L1147/1158 mentioned previously. NGC 7129 is a young cluster containing three B-type stars, namely, BD +65°1637, BD +65°1638 and LkHα234, as well as several low-mass pre-main sequence stars, (Herbig 1960; Strom, Vrba & Strom 1976; Cohen & Schwartz 1983; Magakian et al. 2004; Gutermuth et al. 2004, 2009; Muzerolle et al. 2004; Stelzer & Schulz 2009). Racine (1968) investigated the three above mentioned B-type stars and determined the distance moduli ≈12.2 magnitudes (2750 pc) for BD +65°1637 and 10.0 magnitudes (1000 pc) for BD +65°1638 and LkHα234, and labeled these values as uncertain. Based on Av vs. distance diagram, Shevchenko & Yakubov (1989) determined a distance to NGC 7129 of 1250 pc. Yonekura et al. (1997) found a group of clouds close to NGC 7129, and their result suggests that a consid-

erable part of the Cepheus Flare clouds is located at a distance of about 1 kpc. The situation is, however, far from being clear (see, e.g. Kun et al. 2008). Simonson & van Someren Greve (1976) found a large HI cloud coinciding both, in position and velocity, with the molecular clouds of Yonekura et al. (1997). They associated this cloud not with NGC 7129, but with the reflection nebulae of Cep R2 (Racine 1968) lying at a distance of 400 pc.

The old open cluster NGC 7142 is located at the Galactic latitude $+9.5^{\circ}$. The surrounding area exhibits a large number of molecular and dust clouds (see a recent review of this area by Kun et al. 2008). The cluster NGC 7142 is located only $0.4^{\circ}$from the reflection nebula mentioned above the young open cluster NGC 7129. The nebula is surrounded by the clump P2 of the dust cloud TGU 645 identified in the Dobashi et al. (2005) atlas of dark clouds. The distribution of the 100 μm emission (Schlegel et al. 1998) shows that NGC 7142 is partly covered by the periphery of the above mentioned dust cloud.

The first photometric investigations of NGC 7142 in the *UBV* system, published in the 1960, used the photographic method with standard stars measured photoelectrically. The *V* vs. *B–V* diagram of NGC 7142 first published by Hoag et al. (1961), which revealed the sequence of red giants and a crowding of stars near the turn-off point of the main sequence. In the presence of large scatter, the limiting magnitude (V=16.5) was not sufficient to cover the main sequence of stars below the turn-off point. Therefore, the reddening and distance of the cluster were estimated only approximately (Johnson et al. 1961). Van Den Bergh (1962) firstly noted that general features of the color-magnitude diagram of NGC 7142 showing a strong resemblance to those of the old open clusters M67 and NGC 188. He also draw attention to the presence of irregularities of the absorbing cloud close to the cluster. Sharov (1968) focused attention on the presence of the group of stars close to the main sequence, but located to the left from the turn-off point (blue stragglers). The other photometric investigation of NGC 7142, published by van den Bergh & Heeringa (1970), extends down to $V\approx$17 magnitude. Based on the similarity of NGC 7142 morphology to that of M 67, they determined a distance modulus of 12.5 mag (3160 pc) and the color excess $E(B–V)$= 0.41 mag adopting an evolutionary track of M 67.

The first CCD photometry of the cluster in the *BV* system, down to V=18 mag,

was published by Crinklaw & Talbert (1991). They confirmed a considerably variable extinction across the face of the cluster, suspected earlier by other authors, with differences in reddening found to be of the order of $\Delta E(B–V)$=0.1 mag. Their colour- magnitude diagram was dereddened with a mean value of $E(B–V)$=0.35 mag and gave the distance modulus 11.4 mag (1.9 kpc) by main-sequence fitting to the ZAMS. They also suspected a rich binary star population present in the cluster.

The most recent CCD photometry of NGC 7142 has been done by Janes & Hoq (2011) and Sandquist et al. (2011) in the *BVI* system down to V=20–21 mag. In the both investigations for determining the distance and age were determined using the red clump giants and the turn-off point of the main sequence, by comparing their positions with theoretical isochrones and with the sequence of the old cluster M 67. In both papers the resulting colour excesses are in full agreement, $E(B–V)$=0.32. The true distance moduli are also very close, 11.85 mag (2.3 kpc) and 11.9 mag (2.4 kpc). However, the age of the cluster determined by Janes & Hoq is 6.9 Gyr, while Sandquist et al. find ≈3 Gyr.

In this thesis the research material is described in six parts - the introduction, five sections, the references and appendix. Section 1 is devoted to a description and reductions of the observational material received by the Maksutov and VATT telescopes equipped with the filters of the Vilnius photometric system. The section is divided into three subsections describing the observations performed by the Maksutov telescope in three 1.5 square degree areas: NGC 7023 (Sec. 1.1), TGU 619 (Sec. 1.2) and NGC 7129 + NGC 7142 (Sec. 1.3). In the third area, observations were also obtained in two smaller fields with the Vatican Advanced Technology Telescope (VATT) in the direction of the open clusters NGC 7129 and NGC 7142 (Sec. 1.3). We also present the observing logs listing the exposure lengths used. The results of photometry are given in the catalogs presented in the Appendix.

Section 2 describes the methods of two-dimentional classification of stars based on the photometric data. The section is divided into two subsections, because the classification programs used for the reflection nebula NGC 7023 and the cloud complex TGU 619 (Sec. 2.1) and for the clusters NGC 7129 + NGC 7142 (Sec. 2.2), were different. A detailed description of the both classification programs is presented.

Section 3 deals with the methods for determinating distances to the star forming regions. The section is divided into three subsections describing the determination of distances to the reflection nebula NGC 7023 (Sec. 3.1), to the dark clouds of the TGU 619 complex (Sec. 3.2) and the clusters NGC 7129 + NGC 7142 (Sec. 3.3). The determination of distance to NGC 7023 and TGU 619 areas is based on the extinction vs. distance diagrams. Sec. 3.3, describing the clusters NGC 7129 and NGC 7142, is much longer, since for the determination of parameters we applied not only the extinction vs. distance diagrams, but also the dereddened color-magnitude diagrams with the isochrones, evolutionary tracks and the zero-age main sequence (Kazlauskas et al. 2006) plotted. In order to verify if the interstellar reddening law in the NGC 7129 area is normal, we used the results of infrared photometry from the 2MASS survey (Skrutskie et al. 2006).

Section 4 describes the data analysis and the results obtained in the investigated fields, as well as gives a comparison with the results of other authors . This section also demonstrates the advantage of the technique used in this investigation compared to the technique employed by other authors.

Section 5 summarizes the main results and conclusions.

Aims of the study

The aim of this work is to investigate photometrically three areas in the star forming regions in Cepheus, known as the reflection nebula NGC 7023, the dark cloud TGU 619 and the young open cluster (plus reflection nebula) NGC 7129, in order to determine distances, values of interstellar extinction and ages of the young open cluster NGC 7129 and the distant old open cluster NGC 7142 seen through a semi-transparent window.

Tasks of the study

1. Wide-field CCD photometry in the two 1.5 square degree areas located in the Cepheus Flare at RA=20:40:00, DEC=+67:50:00 and RA=21:44:00, DEC=+65:58:00 in the Vilnius seven-color system down about V=17.5 mag.

2. Deep CCD photometry down to 18.5 - 20.0 mag in the fields of the open clusters NGC 7129 and NGC 7142 located at RA=21:42:56, DEC=+66:06:12 and RA=21:45:10, DEC=+65:46:18.

3. From the photometry to determine spectral and luminosity classes in the MK system, interstellar extinction and distance to the stars by about 2 mag brighter than the limiting magnitude in three 1.5 square degree areas located in the Cepheus Flare.

4. To determine the distances to the dust clouds in the direction of the reflection nebula NGC 7023 and to the dust clouds TGU 619 and TGU 645.

5. To determine ages, distances and the values of interstellar extinction of the open clusters NGC 7129 and NGC 7142.

Scientific novelty

1. In the investigated areas, a multicolor photometry in the Vilnius system for more than 4400 stars was obtained for the first time. For more than 2500 stars, the results of two-dimensional spectral classification have been provided also for the first time.

2. The distances to the dust clouds TGU 619, TGU 629 (NGC 7023) and TGU 645 (NGC 7129) are determined.

3. The reliable determination of distances and ages of the open clusters NGC 7129 and NGC 7142 is given, which improved our previous knowledge of the basic parameters of these star clusters.

Practical importance

The distances to star-forming regions in the Cepheus Flare, an out-of-plane concentration of molecular clouds and interstellar dust, are still unknown to a sufficient accuracy. This work is a successful attempt to determine the distances and extinctions of the selected dust clouds. The results of two-dimensional classification of 2500 stars and their distribution in the areas will put our knowledge of star-forming proceses in this areas on a more reliable basis and allow to know more about the Galactic structure. The catalog of photometry and two-dimentional classification of the studied stars is available on–line and can be used by other researches for future investigations.

Results and statements presented for defence

1. The dust cloud TGU 629 located around the reflection nebula NGC 7023, is found to be at a distance of 282 pc ($^{+73}_{-56}$). At the distance of 715 pc ($^{+186}_{-143}$), another dust layer is detected.

2. The dark cloud TGU 619 is located at a distance of 286 pc ($^{+74}_{-57}$).

3. The distance to the dust cloud TGU 645, which is associated with the young open cluster NGC 7129, is 1150 pc ($^{+293}_{-226}$).

4. The age of NGC 7129, based on six cluster member stars and the stellar evolutionary tracks, is up to 4 Myr, and this shows that the star-forming processes are still continuing.

5. The distance to the cluster NGC 7142 was estimated using five red clump giants identified as the cluster members by their distances and radial velocities, is 2.3 kpc.

6. The dereddened color-magnitude diagram for possible members of NGC 7142, compared with the Padova isochrones, gives the cluster age 3.0 ± 0.5 Gyr.

Personal contribution

The author participated in most of the CCD observations with the Maksutov telescope of the Moletai Observatory and performed the data reductions with the IRAF program package. The author took part in photometric classification of the observed stars and in the analysis of the interstellar extinctions, distances and ages of the clusters. He also collected the data from the literature and data bases and participated in the preparation of the articles related to this study.

Thesis outline

The dissertation consists of six main parts: Introduction, five chapters, References, and Appendix.

Chapter 1 presents the observational material obtained with the Maksutov and VATT telescopes.

Chapter 2 describes the methods of two-dimentional classification of stars based on photometric data.

Chapter 3 describes the method for the determination of distances to the star forming regions.

Chapter 4 provides the data analysis and the results in the investigated fields and compares the results with the results of other authors.

Chapter 5 summarizes the main results and conclusions.

Chapter 1

Observational data

Observational data of this work cover the vicinity of the reflection nebula NGC 7023, dark cloud TGU 619, young open cluster NGC 7129 and old open cluster NGC 7142. The CCD observations in the seven filters of the Vilnius system were obtained with the Maksutov 35/51 telescope of the Molėtai Observatory of Vilnius university in Lithuania for all the listed areas. For the clusters NGC 7129 and NGC 7142, deeper photometry in the same system but in smaller areas were obtained with the 1.8 m VATT telescope of the Vatican Observatory on Mt. Graham.

1.1. Reflection nebula NGC 7023

One of the most prominent objects in the Cepheus Flare is the star-forming region near its eastern edge which contains the reflection nebula NGC 7023 illuminated by the Herbig Ae/Be star HD 200775. The nebula is surrounded by a group of dust clouds L 1167, L 1168 and L 1170–1174 (Lynds 1962) which in the newest atlas of dust clouds of Dobashi et al. (2005) are joined into a single cloud TGU 629.

In the *Vilnius* seven-color photometric system the area was first investigated by Straižys et al. (1992, hereafter Paper SCKM-92) who estimated the distances to two groups of dust clouds in the Cepheus Flare from the extinction A_V vs. distance plots based on two-dimensional classification of 79 stars measured photoelectrically. The distance to the clouds, surrounding the NGC 7023 nebula, was found to be 288 pc. However, only 18 stars brighter than $V = 12.5$ were classified in this area. Among these, only six stars were found to be reddened sufficiently to be suitable for estimating the front edge of the dust cloud. For determining the cloud distance more accurately, a statistically significant number of stars is necessary. Therefore we decided to extend the investigation down to $V \approx 16.5$ mag by applying observations

Table 1.1.: The CCD frames used for the NGC 7023 area. The numbers of frames in the same filter with the same exposure are given in brackets.

Filter	λ_0 nm	min/sec	Exposure length and the number of frames
U	345	min	30 (1), 25 (1), 20 (2), 8 (2), 2 (1)
P	374	min	20 (2), 5 (2), 1 (2)
X	405	sec	900 (2), 180 (2), 50 (1), 40 (1), 15 (2)
Y	466	sec	240 (2), 60 (2), 15 (2), 5 (1), 3 (1)
Z	516	sec	180 (2), 60 (2), 15 (2), 3 (2)
V	544	sec	600 (3), 180 (2), 60 (1), 30 (2), 20 (1), 10 (1)
S	656	sec	180 (2), 60 (2), 15 (3), 5 (1), 3 (1), 1 (2)

with CCD techniques.

CCD photometry in the *Vilnius* photometric system of 1240 stars was obtained by scientific supervisor Justas Zdanavičius in an area of about 1.5 square degrees, centered at $\alpha(2000) = 21^{\rm h}01^{\rm m}37^{\rm s}$, $\delta(2000) = +68^\circ09.8'$ ($\ell = 104.1^\circ$, $b = +14.2^\circ$). For most of these stars, spectral and luminosity classes were determined from the photometric data.

The area was observed with the Maksutov 35/51 cm telescope of the Molėtai Observatory, equipped with a VersArray 1300B CCD camera of Roper Scientific, Princeton Instruments. The imaging array of the CCD chip has 1340×1300 pixels of 20×20 μm size. The linear area of the chip is 26.8×26.0 mm, and this corresponds to a field of view of $1.26^\circ \times 1.22^\circ$. The chip was cooled by liquid nitrogen to –110°C. A set of round filters of the *Vilnius* system of 50 mm diameter was used. The ultraviolet *U* and *P* and the green *V* filters are made from colored glasses, and the violet *X*, the blue *Y*, the green *Z* and the red *S* are interference filters. The filter *U* has an additional interference layer cutting the red leak at 700 nm. More details about the instrumentation are given by Zdanavičius & Zdanavičius (2003). The *Vilnius* system is described in detail by Straižys (1992).

The area was observed during the moonless period in 2005 October. The list of the frames used is given in Table 1.1. Part of the exposures were taken with a slight (about 50 pixels) shift in *x* and *y* directions to exclude the influence of some defective pixels.

Sky flats were obtained in each filter from twilight exposures. For the determina-

tion of large-scale field corrections, standard stars in the area were used. With this aim, special exposures with three shifts of about 1/3 of the field and with the rotated field were made. Flat-fielding was done by applying a code described in Laugalys et al. (2004). CCD counts were corrected for a small nonlinearity (Zdanavičius & Zdanavičius 2003).

The magnitudes of stars were obtained with the standard IRAF program package combining aperture and PSF photometry. The PSF function parameters of the images were found to be slightly dependent on the distance from the field center, consequently, small corrections depending on the star position were included. These corrections were determined by comparing magnitudes of brighter stars derived by both methods.

The magnitudes V and color indices m–V were obtained in the following sequence. At the beginning, the instrumental magnitudes m (instr) were determined for individual frames, then they were averaged for each filter. The instrumental color indices m–V (instr) were calculated as the differences between the corresponding instrumental magnitudes. The final values of magnitudes V and color indices were obtained after applying color equations and fixing the zero points. The transformation coefficients of magnitudes and color indices to the standard *Vilnius* system from Zdanavičius & Zdanavičius (2003) were used; they have been determined using photoelectric standards in the M 67 cluster from Laugalys et al. (2004) and other methods. Zero points to the color equations in the area were based on 13 stars measured photoelectrically (Straižys et al. 1992).

1.1.1. The catalog

The results of photometry in the seven-color *Vilnius* photometric system for 1240 stars down to V = 16.7 mag are published by Zdanavičius et al. (2008), which lists the identification number, the J2000 coordinates, V magnitudes, six *Vilnius* color indices and photometric spectral types. The stars are identified in the DSS2-red based charts given in Figures C.2–C.7. The division of the identification chart into sections is shown in Figure C.1. To make the identification easier, all sections overlap by approximately 45^{s} in RA and $2'$ in DEC.

The errors in magnitudes and color indices originate in both the measurement and

the subsequent reductions. The measurement errors are defined by photon statistics and sky background. The reduction errors originate in flat-fielding and transformation to the standard system. The final standard deviations for the stars brighter than 16 mag are about ± 0.015 mag for V and about 0.02 mag for Y–V, Z–V and V–S. The accuracy of U–V, P–V and X–V is somewhat lower, especially for the stars of spectral classes K–M and reddened stars. In the catalog, color indices with σ between 0.05 and 0.10 mag are marked by a colon and those with σ between 0.10 and 0.20 by a double colon. For the faintest and reddest stars the ultraviolet color indices are not given.

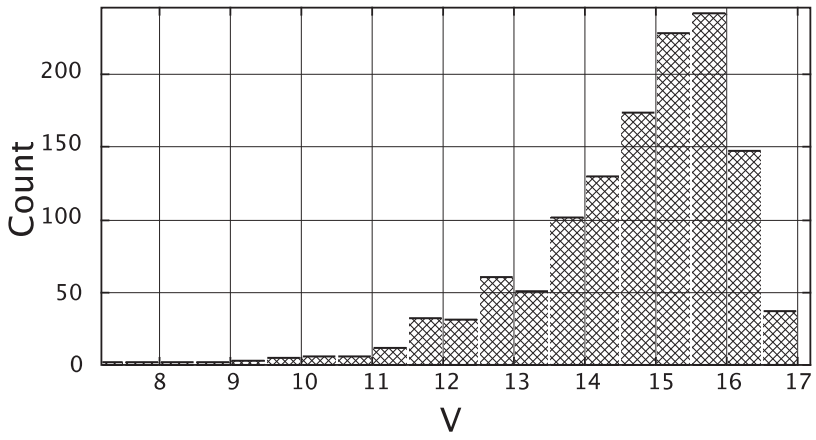

Figure 1.1.: Distribution of the catalog stars Zdanavičius et al. (2008) in 0.5 mag bins of V in NGC 7023 area

Due to the short focus of the telescope (120 cm) and large images (5–8″), the resolution of close stars (which can be both optical and physical) is complicated. By comparing the magnitudes measured with different apertures, we identified binary stars with the separations between the components larger than about 6″. Their magnitudes were measured by the PSF method and should be reliable. Also identified multiple stars with the separations between 3″ and 10″ by inspecting the DSS2 red images in the SkyView Virtual Observatory.

Table 1.2.: The CCD frames used for the TGU 619 area. The numbers of frames in the same filter with the same exposure are given in brackets.

Filter	λ_0 nm	min/sec	Exposure length and the number of frames
U	345	min	20 (3), 8 (2), 2 (2)
P	374	min	20 (3), 5 (2), 1,5 (1), 1 (1)
X	405	sec	900 (3), 180 (2), 40 (2), 15 (2)
Y	466	sec	240 (2), 60 (2), 15 (2), 5 (2)
Z	516	sec	180 (2), 60 (2), 15 (2), 3 (2)
V	544	sec	600 (2), 180 (2), 60 (1), 20 (2)
S	656	sec	180 (2), 60 (2), 20 (2), 5 (1), 4 (2)

1.2. Dark cloud TGU 619

The exposures of the area with the *Vilnius* filters were obtained with the Maksutov telescope of the Molėtai Observatory in Lithuania. The frames listed in Table 1.2 were done in October of 2005 during the same observing run as those for the NGC 7023 area. The reduction methods are the same as described in detail for the reflection nebula NGC 7023.

1.2.1. The catalog

The magnitudes and color indices for 1304 stars brighter than V = 16.6 mag are presented in Table A.1. The stars are identified in Figures C.9–C.14, the split of the area into six sections is shown in Figure C.8.

Table A.2 contains the following information: the identification numbers ZZS [2009], the J2000.0 equatorial coordinates, magnitudes V, color indices U–V, P–V, X–V, Y–V, Z–V and V–S, spectral types in the MK system, interstellar extinction and distance values. Magnitudes and color indices with σ between 0.05 and 0.10 mag are marked by a colon and those with σ between 0.10 and 0.20 by a double colon.

Spectral types of stars were determined by three different methods as described in Zdanavičius et al. (2009). For spectral classes we use the lower-case letters to indicate that our spectral classes are estimated from the photometric data. For some stars the suspected peculiarity types are given: ‘md’ means metal-deficient, ‘d’ means visual binary identified in the SkyView DSS2 red images.

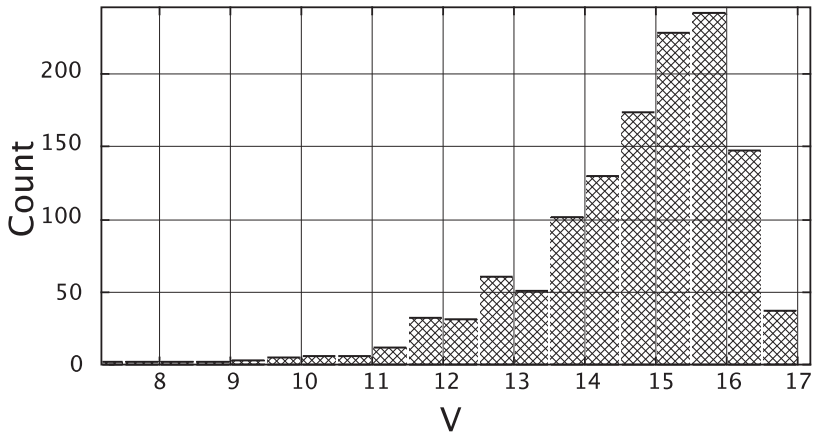

Figure 1.2.: Distribution of the catalog stars in 0.5 mag bins of V in TGU 619 area

1.3. Clusters NGC 7129 and NGC 7142

1.3.1. Observations with the Maksutov telescope

The observations were obtained in September of 2009 with the Maksutov telescope of the Molėtai Observatory in Lithuania, equipped with a Roper Scientific, Princeton Instruments CCD camera.

Magnitudes of stars were obtained by the standard IRAF program package in the aperture mode. Since the investigated area has no standard stars in the *Vilnius* system, for creating a set of local standards we applied the tie-in method with the stars in the direction of the dark cloud TGU 619 located about 7° west and investigated in Zdanavičius et al. (2009b). Short tie-in exposures at similar air masses were obtained during two nights in October of 2009. The duration of exposures was between 5 min in the *U* filter to 10 s in the *S* filter.

The CCD exposures of the field used for photometry are listed in Table 1.3. Different exposure lengths are used to avoid saturation of images of the brightest stars.

1.3.2. The catalog

The results of photometry of 2140 stars down to $V = 17$ mag are given in Table A.2 which lists the identification number, the RA(J2000) and DEC(2000) coordinates taken from the PPMXL catalog, *V* magnitudes and six color indices in the *Vilnius* system and photometric spectral types. For a part of stars color indices *U*–*V* and *P*–*V* are absent since these stars were too faint in the ultraviolet magnitudes *U* and

Table 1.3.: The CCD frames used for clusters NGC 7129 and NGC 7142 observations with the Maksutov-type telescope. The numbers of frames in the same filter with the same exposure are given in brackets.

Filter	λ_0 nm	Exposure length in seconds and the number of frames
U	345	1800 (2), 480 (1), 360 (1), 120 (1)
P	374	1500 (2), 300 (2), 60 (2)
X	405	900 (2), 300 (2), 90 (2), 20 (2)
Y	466	360 (2), 300 (1), 90 (3), 20 (1), 15 (2), 5 (3)
Z	516	240 (2), 60 (2), 15 (2), 5 (2)
V	544	720 (2), 180 (2), 30 (2), 5 (2)
S	656	240 (2), 60 (2), 15 (2), 5 (2)

P. For a few stars colors *V*–*S* are also absent. Color indices *X*–*V*, *Y*–*V* and *Z*–*V* are present for all the stars. A colon following a magnitude or color index means that its error is larger than 0.05 mag but smaller than 0.10 mag. Color indices with larger errors are excluded.

Due to a short focus of the telescope, the CCD pixel size is about $3.4''$, and many stars with the separation $< 7''$ are too close to be measured separately with a sufficient accuracy. Such stars were excluded from the catalog, if their magnitude difference was less than ~ 3 mag. A number of stars, having asymmetrical images in the SkyView DSS2 red images, should be double or multiple (optical or physical) stars with separations $< 3''$. Such stars were included in the catalog, but in the last column, instead of spectral types, they are marked by two asterisks.

The stars which in the 2MASS, Spitzer and WISE surveys have been recognized as YSOs, have the notes at the end of Table A.2. Some of them are identified by us, and some are selected from the literature.

1.3.3. Observations with the 1.8 m VATT telescope

The observations were obtained by (R. P. Boyle) in 2009 October 18–21 with the 1.8 m telescope of the Vatican Observatory on Mt. Graham equipped with a 4K backside illuminated CCD camera and a liquid nitrogen cooling. The camera contains 62×62 mm chip which produces a $13' \times 13'$ field-of-view, with a scale of $0.38''$/pixel. Both clusters were framed with different exposures to ensure the lin-

Table 1.4.: The CCD of NGC 7129 frames used. The numbers of frames in the same filter with the same exposure are given in brackets.

earity of response from $V \approx 9$ mag to the faintest limit.

The CCD frames used for the NGC 7129 and NGC 7142 areas are listed in Tables 1.4 and 1.5. The identefication charts are given in Fig.C.15 - C.20

For the reductions of CCD exposures the IRAF program package in the aperture photometry mode was used. For flat-fielding the twilight and dome exposures were applied. Large-scale systematic errors in the flat fields were corrected by using the exposures of the cluster M 67 with known photometric data in the *Vilnius* system of high accuracy (Laugalys et al. 2004). Preliminary color equations for the reduction of magnitudes and color indices of stars from the instrumental to the standard system were obtained from observations of M 67. Zero-points of magnitudes in the *Vilnius* system were based on common stars with the previous catalog (Table A.2): 34 stars in the NGC 7129 area and 117 stars in the NGC 7142 area. The

final adjustment of color equations and zero-points has been done by optimizing the accuracy of photometric classification of a selected set of stars in the investigated areas (Laugalys 2012).

For 850 of stars photometric spectral and luminosity classes were determined. The classification methods are described in chapter 2 of this work.

1.3.4. The catalogs in the NGC 7129 and NGC 7142 areas

Magnitudes and colors in the NGC 7129 and NGC 7142 areas are given in Tables A.3 and A.4 for 159 and 1037 stars, respectively. The limiting magnitude V in the NGC 7129 area is 18.8, in the NGC 7142 area it is 20.1 mag.

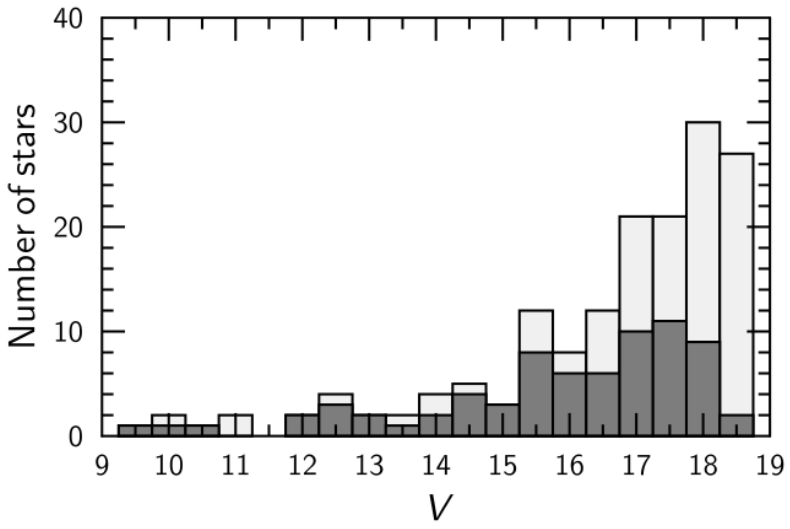

Figure 1.3.: Distribution of the measured stars in the NGC 7129 area (Table A.3) in apparent magnitudes. The shadowed parts of the columns correspond to stars for which two-dimensional spectral types were determined (Table B.3).

The accuracy of the magnitudes V and color indices X–V, Y–V, Z–V and V–S to V = 16 mag is usually better than 0.02 mag, the accuracy of U–V and P–V is about 1.5–2.0 times lower. At $V \approx 18.5$ mag, the accuracy of photometry is too low for a reliable classification of stars. The U-V and P–V color indices for the stars fainter than V = 19.0 mag in most frequently are not given.

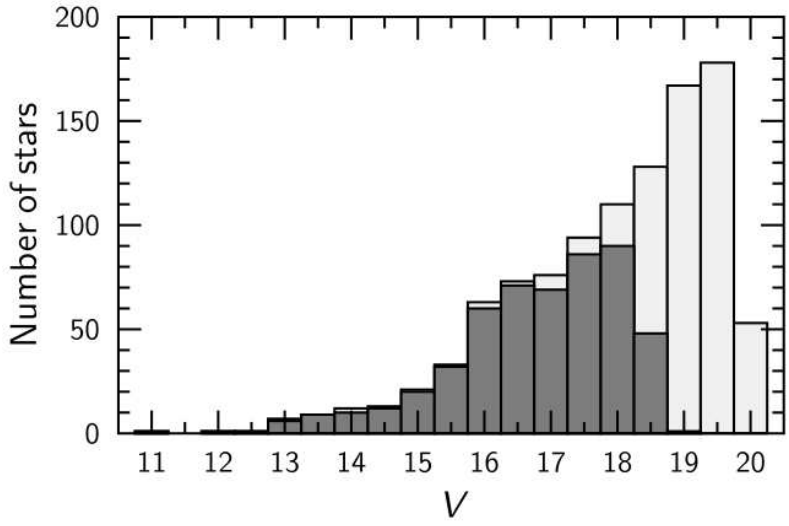

Figure 1.4.: Distribution of the measured stars in the NGC 7142 area (Table A.4) in apparent magnitudes. The shadowed parts of the columns correspond to stars for which two-dimensional spectral types were determined (Table B.5).

The columns list the following information: star number, equatorial coordinates J2000.0, magnitude V, color indices U–V, P–V, X–V, Y–V, Z–V and V–S, and photometric spectral type in the MK system. The magnitudes V with $\sigma > 0.03$ mag and color indices with $\sigma > 0.05$ mag are marked with colons. Notes at the end of the tables contain the HD, BD numbers, spectroscopic MK types, peculiarity types, binarity, variability and other information available in the literature. The ID numbers of stars having notes at the end of the catalogs are indicated with asterisks. The stars found to be binaries or having asymmetric images were not classified in spectral and luminosity classes – they are designated by double asterisks in the column of spectral types. The coordinates of stars are taken from the PPMXL catalog (Roeser et al. 2010).

Chapter 2

Two-dimentional classification of stars

Classification of stars is done by various reddening-free Q-parameters and Q,Q diagrams calibrated in terms of spectral classes and absolute magnitudes (Straižys et al. 1992).

Q-parameters are defined by the equation.

$$Q_{1234} = (m_1 - m_2) - (E_{12}/E_{34})(m_3 - m_4), \tag{2.1}$$

2.1. Classification of stars in the NGC 7023 and TGU 619 areas

For the classification of stars a few different codes were used.

1. The COMPAR code, based on the σQ method described by Straižys et al. (1992, 2002). The method uses match of 14 different interstellar reddening-free Q-parameters of a program star to those of several thousand standard stars (from 8000 to 13000) of various spectral and luminosity classes, metallicities and peculiarity types.

2. The COMPAR 2 method used ten Q-parameters (Q_{UPYV}, Q_{UPY}, Q_{UXY}, Q_{UYV}, Q_{PXY}, Q_{PYV}, Q_{XYV}, Q_{XZS}, Q_{YZV}, Q_{YVS}), calculated for 1418 "standards", formed for 89 spectral subclasses and 17 values of absolute magnitudes derived from the mean intrinsic color indices taken from two sources: (1) Straižys (1992), but with absolute magnitudes adjusted to the distance scale based on the *Hipparcos* parallaxes and linearly interpolated for missing subclasses, (2) a new set of intrinsic color indices obtained from new observations of $\sim$600 stars with the reliable *Hipparcos* parallaxes, made by A. Kazlauskas and others (unpublished). For each program star,

ΔQ_i, the differences between its Q_i-parameters and the corresponding Q_i-parameters of the 1418 standards were calculated. After that, the standards for where

$$\Delta Q_i < N\sigma_{Q_i} \tag{2.2}$$

were selected, beginning with N=1. Here σ_{Q_i} are the rms errors of the parameters Q_i, evaluated from the rms of the observed color indices, and N is the size of the error box. If N=1, the probability to find the true Q_i value between $Q_i - \delta Q_i$ and $Q_i + \delta Q_i$ is 68%, if N=2 the probability is 95%, if N=3 the probability is 99%. A rough mean spectral class and M_V of the standards found in the box are accepted for the program star (on somewhat subjective grounds). If no standard have appeared in the N=1 box, the value of N was increased and the search repeated. If no standard was found in the $4\sigma_{Q_i}$ box, the program star was accepted as peculiar.

3. The xqKLAS code, based on the xq-method described by Zdanavičius (2005). The method is based on a new concept of reddening-free parameters (q) close to normal color indices for "true" Spectral type and a 'virtual' quantity of the interstellar dust (x).

Finding the closest standard star by fitting the reddening-free q-parameters of a program star with those calculated for a set of standards – 684 synthetic stars of various MK spectral types with intrinsic color indices and absolute magnitudes taken mainly from the Straižys (1992) monograph. First until 20 of the closest standards are found. Taking Sp and M_V values of these standards, the color excess, intrinsic color indices and virtual interstellar mass, and their differences from corresponding color indices of standards, are calculated for all intrinsic color indices found. The parameters of a standard with minimal mean difference are attributed to a program star. If mean differences coincide within the errors, the standard with minimal difference of virtual masses is taken. Otherwise it is assumed that star is pecular or double.

4. The TINKLAS code, which classifies stars using various Q_i vs. Q_j diagrams (Straižys 1992). Each of them is formed from two reddening-free Q-parameters and calibrated in terms of spectral classes and absolute magnitudes. The color excess E_{B-V} is calculated from color excesses of the *Vilnius* system, mainly from E_{Y-V}, but for the accuracy control the excesses E_{X-V}, E_{Z-V} and E_{V-S} were used, too. A_V

is calculated from E_{B-V} using the ratio R=A_V/E_{B-V}.

This method was the first used for photometric classification of stars using the Vilnius multicolor phorometry.

In most cases, different methods give the spectral classes which agree within one spectral subclass. The differences of the absolute magnitudes usually are of several tenths of magnitude. However, for some stars the differences may be as great as 3 – 5 mag (low accuracy photometry). For some spectral subclasses, small systematic differences between the methods exsist. The main reason of this are different calibrations used in the programs.

Spectral and luminosity classes determined by different methods for each star were weighted and averaged. Additionally, in some complicated cases, we used various two-color diagrams, combined with the intrinsic sequences of different luminosity classes, trying to avoid ambiguity of spectral or luminosity classes. The infrared J–H and H–K_s color indices from the 2MASS survey were helpful for the recognition of K and M dwarfs.

2.2. Classification of stars in the NGC 7129 and NGC 7142 areas

In order to improve a two-dimensional classification of stars, new classification programs have been used. More details of the programs are described below.

Spectral types of stars from *Vilnius* photometry were determined by two codes. The first one is a version of the COMPAR code composed by A. Kazlauskas and described recently by Straižys et al. (2013). The second classification code named 'QQQ' was composed by K. Zdanavičius and is described here. The results of classification with the COMPAR and QQQ codes were compared and averaged.

The classification by the QQQ code is based on intrinsic color indices for 300 types of two-dimensional MK types (spectral and luminosity classes) taken from the Straižys (1992) monograph. The classification code includes the following three stages.

(1) 14 interstellar reddening-free Q-parameters are calculated from the intrinsic color indices for 300 MK types. In calculation of the Q-parameters, the ratios of

color excesses corresponding to the normal interstellar reddening law are taken. The same Q-parameters are calculated for the program stars. Next, for each program star these 14 Q-parameters are matched up with the set of 300 standards to find the MK type which shows the least standard deviation.

(2) The next classification stage is based on six intrinsic color indices which include the passbands X, Y, Z and V (X–Y, X–Z, X–V, Y–Z, Y–V and Z–V). Differerences of the observed color indices of a program star and the corresponding intrinsic color indices of the 300 MK standards are calculated giving the spurious 'color excesses' which for convenience are all transformed to the values of interstellar dust mass x (in the scale when $A_V = x = 1$). The values of $x < -0.15$ are rejected. The analysis of x values for each program star (corresponding to different color indices) allows to find the standard for which the dispersion of the six x values is at minimum. This value of x should be close to the real interstellar dust mass which affects this star, and the corresponding spectral type can be accepted for the program star.

(3) The accepted spectral type of a program star and its dust mass allows to deredden all its color indices. We can compare the dereddened indices with the intrinsic color indices of a set of standard 300 MK types, find a minimum dispersion of six color indices and to estimate again the spectral type of this program star.

Finally, the mean of these three optimum values of MK types are calculated. The dispersion of these three values serves for the estimation of the classification reliability. Interstellar reddening and extinction for each of the classified stars is determined together with its spectral type.

According to the values of this dispersion of the parameters of the first three most sutable standards, we estimate the accuracy grades of the accepted spectral types: 1 means reliable, 2 means satisfactory, 3 means doubtful and 4 means uncertain classification.

All the described methods for the estimation of spectral types are not independent since they are based on the same set of intrinsic color indices. However, the methods do not give strictely identical results due to the presence of observational errors and the cosmic dispersion of the intrinsic color indices.

Additionally, for the identification of stars with different peculiarities (emission-line stars, Am and Ap stars, subdwarfs, metal-deficient giants, binaries) a few Q_1 vs. Q_2 diagrams have been analyzed. The two-Q diagrams were selected to give the

largest separation of peculiar stars from the sequences of normal stars of different luminosities.

In the COMPAR codes, peculiar stars are identified in the *Q*-matching process since the comparison catalog, except of normal stars of various spectral and luminosity classes, also contains stars with different peculiarities.

For the identification of young stellar objects among the stars measured in the *Vilnius* photometric system, we used several two-color plots of infrared surveys: the *J*–*H* vs. *H*–K_s diagram of the 2MASS survey, the diagrams [3.6]–[4.5] vs. [5.8]–[8.0] and [3.6]–[4.5] vs. [4.5]–[24.0] of the Spitzer survey, and the combined K_s–[3.4] vs. [3.4]–[4.6] diagram of the 2MASS and WISE surveys. The details of application of the 2MASS and WISE diagrams are described in (Straižys et al. 2013).

Chapter 3

Distance determination to the star forming regions

For the classified stars we determined color excesses E_{Y-V}, interstellar extinctions A_V and distances d by the following equations:

$$E_{Y-V} = (Y-V)_{\rm obs} - (Y-V)_0, \tag{3.1}$$

$$A_V = 4.16 E_{Y-V}, \tag{3.2}$$

$$5 \log d = V - M_V + 5 - A_V, \tag{3.3}$$

3.1. Distance to the reflection nebula NGC 7023

The interstellar reddenings E_{Y-V} of 480 stars with the most reliable classification were determined as differences between the observed color indices Y–V published by Zdanavičius et al. (2008) and the intrinsic color indices $(Y–V)_0$ for a given spectral type taken from Tables 67–69 of the Straižys (1992) monograph. Color excesses were transformed to extinctions by the equation (3.2). Distances d to the stars in parsecs were calculated by the equation (3.3). Here V are from Zdanavičius et al. (2008) and M_V are from the tabulation given in Straižys (1992), adjusted to a Hyades distance modulus of 3.3 mag. The results are given in Table B.1 which gives interstellar extinctions A_V, distances d and the name of the subarea to which the star is attributed. The subareas with different extinctions are described below in this section and are shown in Figure 3.1.

Figure 3.2 shows the plot A_V vs. d for stars in the whole area. The three dotted curves correspond to A0 V (or K0 III), F0 V and G0 V stars at the limiting magnitude $V_{\rm lim}$ = 16.0. The stars of these spectral types (and absolutely fainter) above the corresponding curves are affected by the limiting magnitude, i.e., stars with high

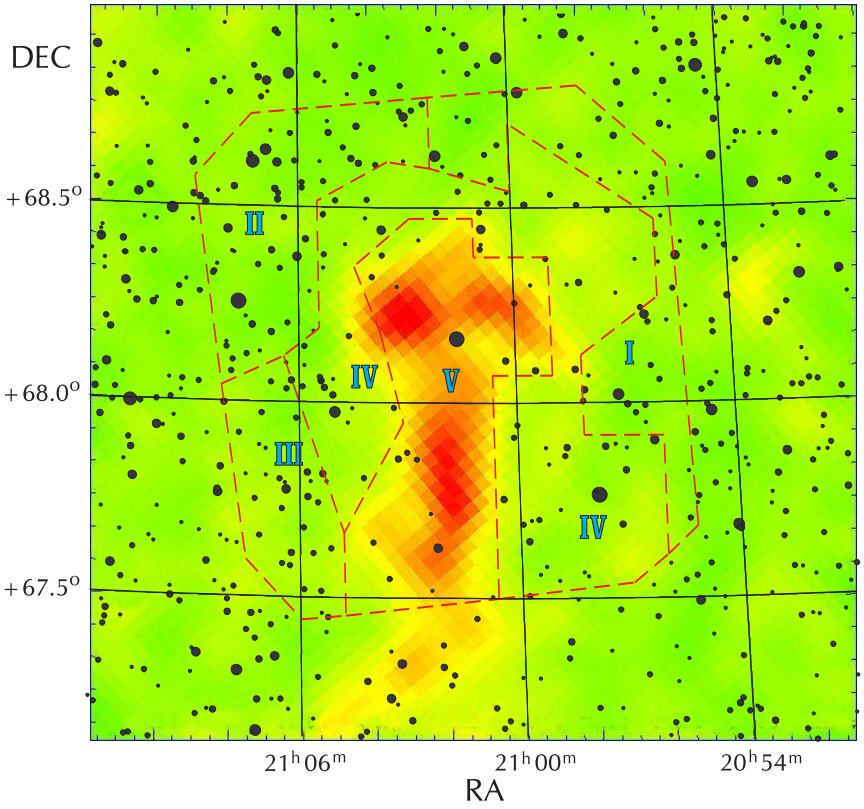

Figure 3.1.: The division of the investigated area into five subareas exhibiting slightly different dependencies of A_V on distance. The extinction map from Dobashi et al. (2005) atlas and the stars down to $V = 14$ from GSC are shown in the background.

extinctions are missing at these distances. Consequently, the plot cannot be used for estimating both the mean and the maximum extinctions. However, up to a distance of 1 kpc all the stars absolutely brighter than G0 V are well represented in the areas where A_V is smaller than ~ 2 mag. At $d = 1$ kpc and $A_V = 2$ mag, only G, K and M dwarfs near the limiting magnitude are missing. In the upper part of Figure 3.2 the error bars of the distance and A_V are shown for the two distance values. They correspond to an error of ± 0.1 mag in A_V, ± 0.5 mag in M_V and (–20, +26) % in the distance.

The segmented curve in Figure 3.2, which starts from the origin of the coordinates, corresponds to the exponential extinction law for the Galactic latitude $b = +14.2°$, calculated by the Parenago formula with the extinction coefficient $A_V = 1.5$ mag/kpc and the half-thickness of the dust layer $\beta = 0.11$ kpc (Parenago 1945; Sharov 1963; Straižys 1992, p. 146). It is evident that the Parenago curve is in agreement with the positions of low-extinction stars located closer to us than 500–700 pc.

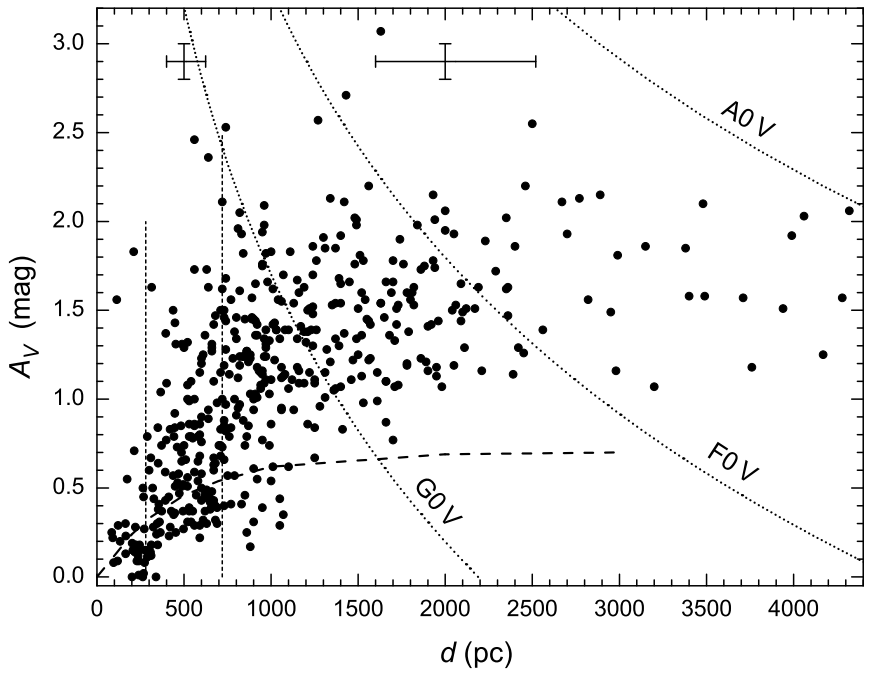

Figure 3.2.: Dependence of the A_V extinction on distance in the whole area. The three dotted curves show the limiting magnitude (V=16) effect for A0 V, F0 V and G0 V stars. The curve at the right-hand upper corner is also valid for K0 III stars since their absolute magnitudes are close to those of A0 V stars. The lower segmented curve is the dependence of the extinction on distance for the Galactic latitude +14.2° calculated by the Parenago formula (see the text). The error bars correspond to standard deviations of the distance and the extinction at 0.5 kpc and 2 kpc distances. The two vertical lines mark the mean distances of the clouds.

For determining the distance to a dark cloud we usually use stars situated at a steep rise (or jump) of the extinction at the front edge of the cloud. However, some of these stars can have negative distance errors which originate mainly from the errors in their absolute magnitudes. Consequently, the true distance to the cloud can be larger than the distance corresponding to the jump defined by the stars apparently closest to the Sun. The true distance can be found as d (min) = 0.79 d, or d (max) =d1.26, where is the distance error when the error of the absolute magnitude ΔM_V = +0.5.

In Figure 3.2 we can see that at $\sim$250 pc a steep rise in the extinction takes place. However, two of the stars, Nos. 595 and 636 in the catalog, exhibit too large extinction values, A_V = 1.56 and 0.55 mag, at small distances, 114 pc and 173 pc, respectively. The first of these two stars will be discussed below in this section. Both stars are excluded from determining the cloud distance. The remaining 10 stars

with distances between 210 and 330 pc and $A_V \geq 0.5$ mag have the mean distance 282 ± 42 pc (standard deviation) which may be considered as the distance of the nearest cloud. This result should be considered as more accurate than the value of distance found by Straižys et al. (1992) applying a similar method for only four stars of magnitudes 11–12. Two of them in (Zdanavičius et al. 2008) were suspected as binaries.

At distances larger than 250 pc the extinction continues to rise almost up to 1 kpc. However, the presence of another jump (or jumps) of the extinction can be suspected. The most probable jump is observed between 560 and 875 pc, where 560 pc is the distance to the front edge, and the distance range is defined by $d - 0.20d$ and $d + 0.26d$. Within this distance range we have 10 stars with $A_V \geq 1.8$ mag. Their mean distance is 715 ± 110 pc (standard deviation).

Trying to better understand the extinction vs. distance relation, we have split the investigated field into five subareas with the boundaries shown in Figure 3.1 and with the extinction map from the Dobashi et al. (2005) atlas and the stars down $V = 14$ mag from the GSC catalog plotted in the background. Each of these subareas exhibits a somewhat different form of the A_V vs. distance dependence. In the following, the results of the extinction dependence on distance in these subareas will be described.

Figure 3.3 shows the A_V vs. d plot for Subarea I located along the right edge of the field. The first two reddened stars with A_V between 0.6–0.8 mag are seen at an apparent distance of ~ 290 pc, i.e., quite close to the mean distance of the first cloud estimated from Figure 1. A few more jumps between 500 pc and 750 pc are also possible. The mean extinction value at distances > 1.0 kpc is about 1.3 mag, and the maximum value is close to 1.75 mag.

Figure 3.4 shows the A_V vs. d plot for Subarea II located at the left upper corner of the area. Here, the nearest considerably reddened star is found at the apparent distance 300 pc, and the second jump is seen at ~ 700 pc. At $d > 1$ kpc the extinction remains more or less constant with a mean value of 1.3 mag. In this subarea a group of about 12 stars at a distance of 800–1100 pc exhibits quite low extinction, with the values between 0.2 and 0.6 mag. Probably, these stars are seen in the directions of relatively transparent windows. They are scattered over the whole subarea.

Figure 3.5 shows the A_V vs. d plot for Subarea III located at the lower left corner

of the field. The positions of the two extinction jumps here cannot be estimated reliably but the height of the second jump is almost 1 mag, giving a mean extinction of 1.8 mag at $d > 1$ kpc.

Figure 3.6 shows the A_V vs. d plot for Subarea IV which surrounds the central dark cloud on three sides. The extinction jumps are close to the distances observed in other subareas. The extinction values show a considerable scatter (between 1.0 and 2.2 mag), with the mean value being about 1.6 mag. Two stars in the subarea exhibit the extinction values around 2.5 mag.

In Figure 3.7 we show the A_V vs. d plot for Subarea V which includes the darkest segment of the dust cloud with the reflection nebula NGC 7023. Only 14 classified stars with $A_V > 1.0$ have been found in this direction. Among these the most interesting is the above-mentioned star No. 595. Its photometric spectral type is K2 V, V = 13.18, A_V = 1.56 and d = 114 pc. It is strange to find this large extinction at such a small distance. The classification of the star by all of the methods applied is of good accuracy and coinciding. The small apparent distance of the star can be explained by its possible duplicity. If it is a binary with two identical components, the combined absolute magnitude should be more negative by 0.75 mag and the distance larger by a factor of 1.41, i.e., 114×1.41 = 161 pc, which is more realistic

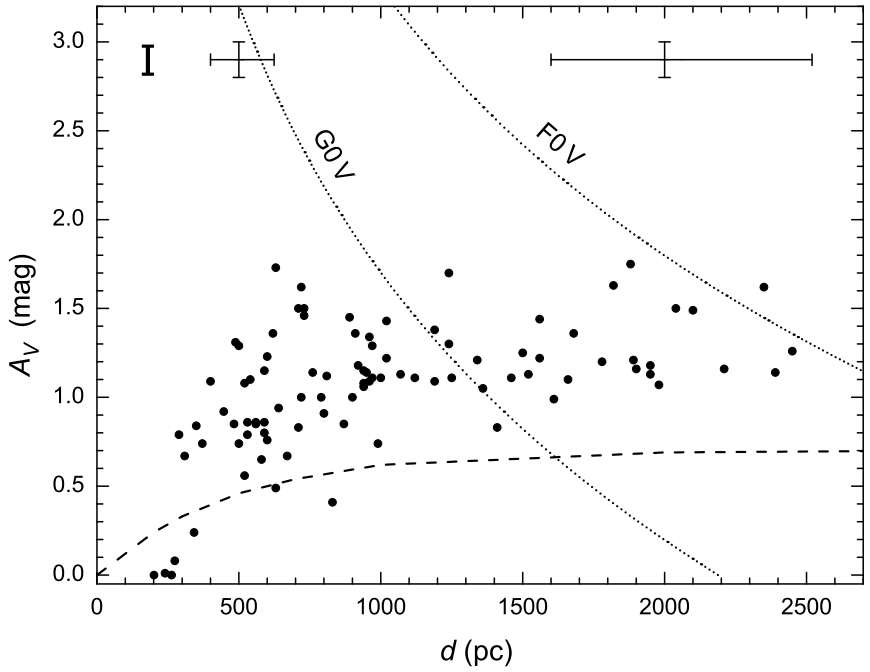

Figure 3.3.: The same as in Figure 1 but for Subarea I.

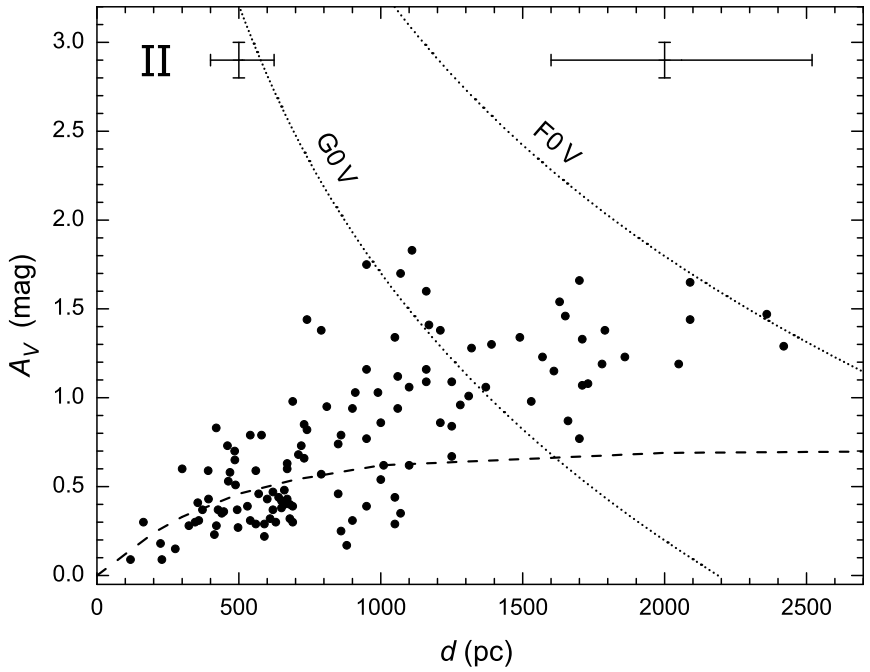

Figure 3.4.: The same as in Figure 1 but for Subarea II.

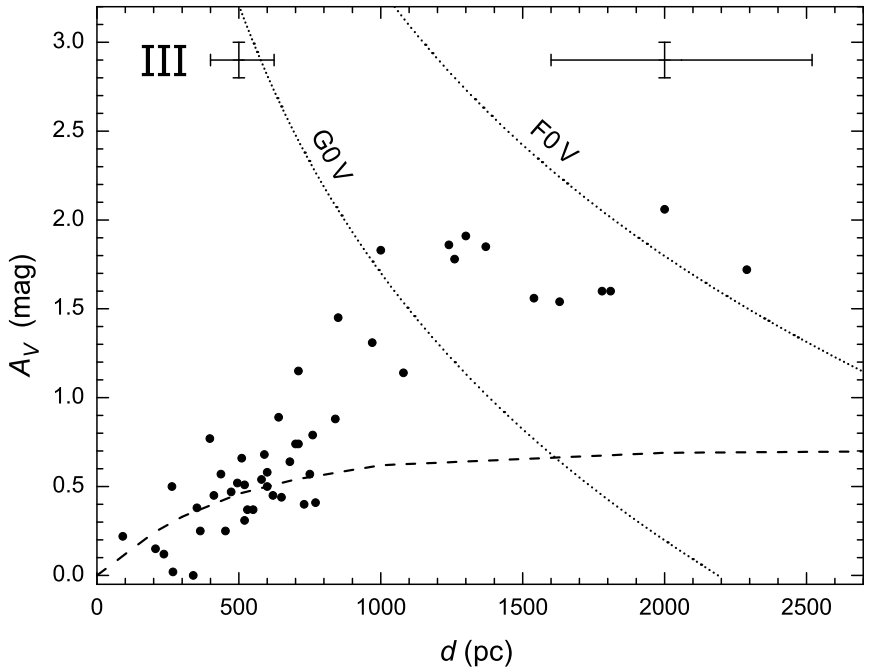

Figure 3.5.: The same as in Figure 1 but for Subarea III.

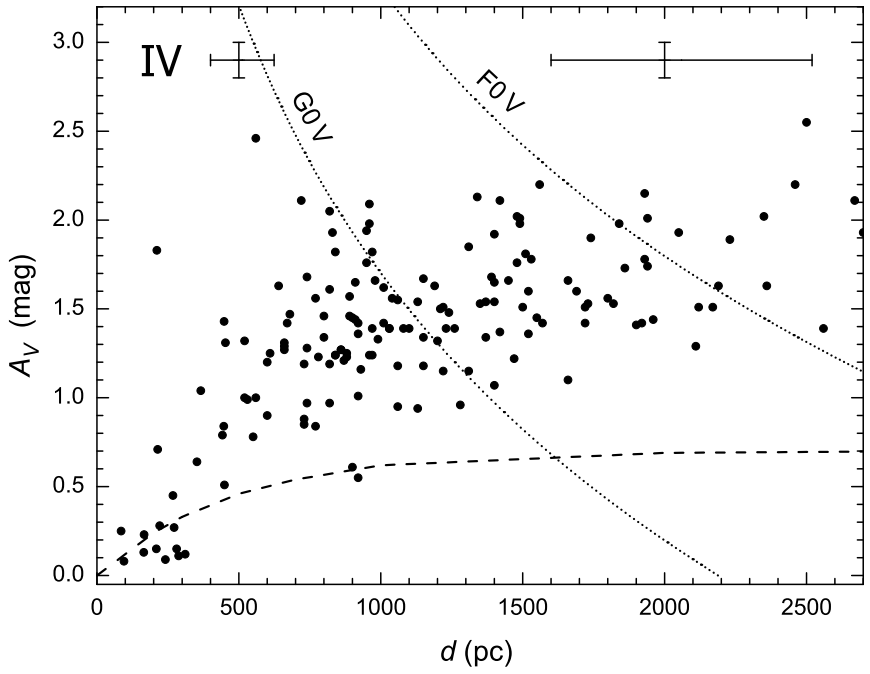

Figure 3.6.: The same as in Figure 1 but for Subarea IV.

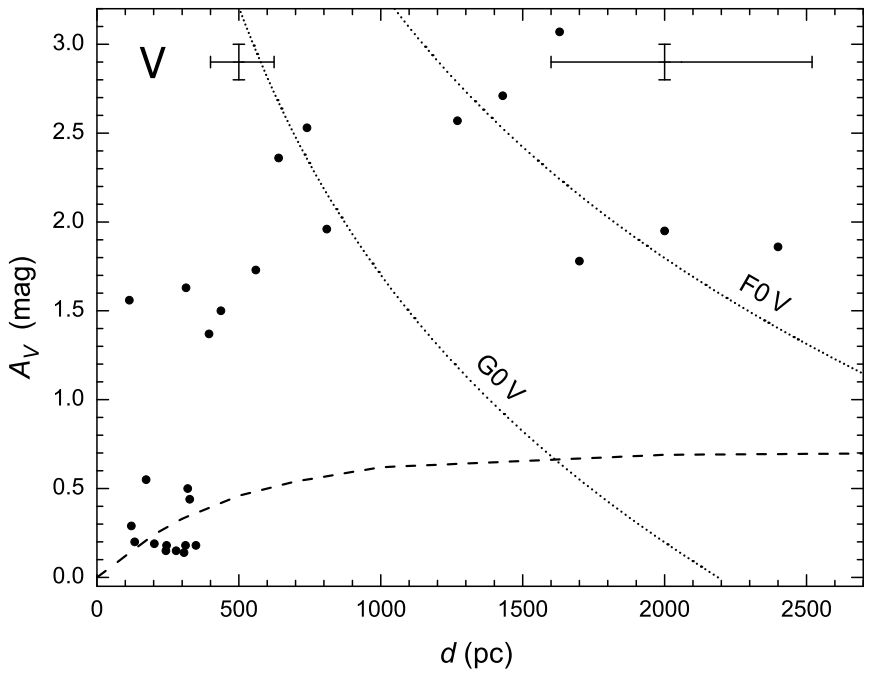

Figure 3.7.: The same as in Figure 1 but for Subarea V.

than the value for a single star, but still too small compared to the cloud distances in other subareas.

Other stars in Subarea V classified in Paper I are too scanty to estimate cloud distances. However, their distribution in the plot (Figure 7) is not in contradiction to the apparent distances of the two clouds at 282 pc and 715 pc. The largest extinction found in Subarea V is close to 3 mag, but this is not the real maximum value since the stars with larger extinctions are absent in our sample due to the limiting magnitude effect.

3.2. Distance to the dark cloud TGU 619

Applying 658 stars with most reliable classification (Table B.2), we investigate the distribution of the interstellar extinction with distance.

The plot A_V vs. d for stars in the area is shown in Figure 3.9. The three dotted curves correspond to A0 V (or K0 III), A5 V and F0 V stars at the limiting magnitude $V_{\rm lim}$ = 16.0. The stars of these spectral types (and absolutely fainter) above the corresponding curves due to limiting magnitude are missing. Thus, the plot cannot be used for estimating both – the mean and the maximum extinctions in the cloud directions. In the upper part of Figure 3.9 the error bars of the distance and A_V are shown for the two distance values (500 pc and 2 kpc). They correspond to an absolute error of $\pm\,0.1$ mag in A_V, $\pm\,0.5$ mag in M_V and (–20, +26) % in the distance.

Figure 3.9 also shows a segmented curve corresponding to the exponential extinction law for the Galactic latitude $b = +15.5^\circ$, calculated by the Parenago formula with the extinction coefficient $A_V = 1.25$ mag/kpc and the half-thickness of the dust layer $\beta = 0.11$ kpc (Parenago 1945; Sharov 1963; Straižys 1992, p. 146). The curve is in agreement with the distribution of low-extinction stars.

The front edge of the dust clouds of the Cepheus Flare can be estimated from the position of stars located at a steep rise of the extinction. Since some of these stars can have negative distance errors, the true distance to the cloud should be larger than the distance to the reddened stars apparently closest to the Sun. The true distance can be found as $d = d$ (front) + 0.2 d, or $d = d$ (front) / 0.8, where 0.2 d is the negative distance error when the error of the absolute magnitude $\Delta M_V = +0.5$.

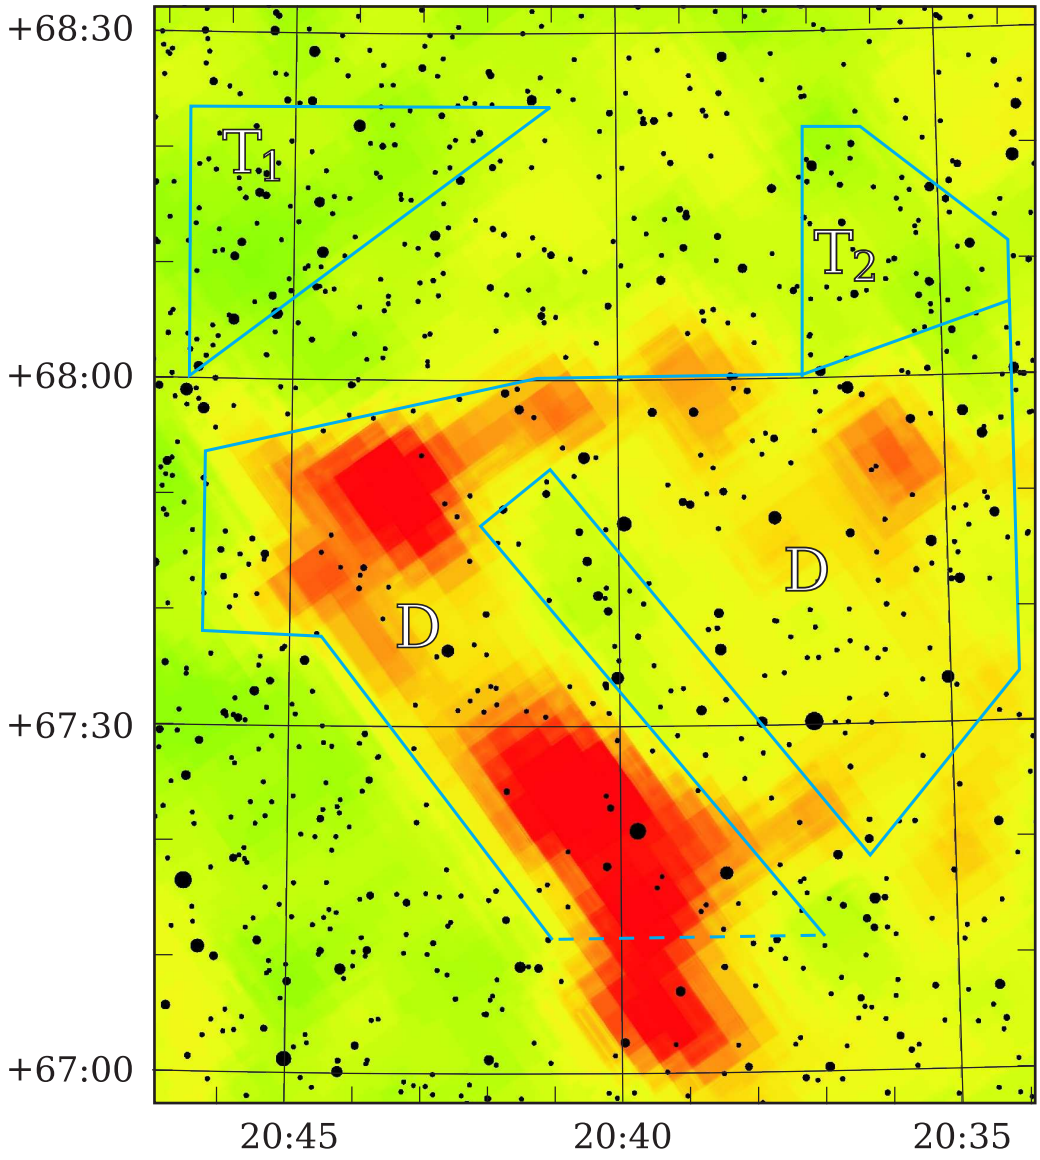

Figure 3.8.: The investigated area: the extinction map from Dobashi et al. (2005) atlas and the stars down to $V = 15$ in the background. The stars are plotted by the Chartes du Ciel (Sky Charts) from the UCAC3 catalog supplemented with Tycho 2. The blue lines limit two most transparent (T_1 and T_2) and the dark subareas (D).

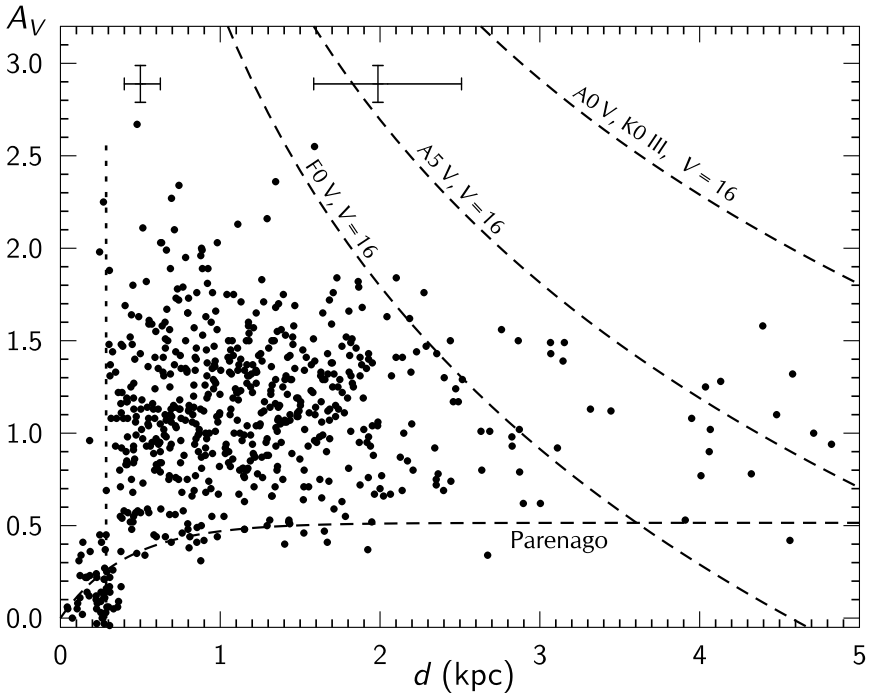

Figure 3.9.: The dependence of the extinction on distance for the whole area. The three dotted curves show the limiting magnitude effect for A0 V, A5 V and F0 V stars. The A0 V curve is also valid for K0 III giants. The lower segmented curve is the dependence of the extinction on distance for the Galactic latitude +15.5° calculated by the Parenago formula (see the text). The error bars correspond to standard deviations of the distance and the extinction at 0.5 kpc and 2 kpc distances. The dotted vertical line marks the estimated distance of the dust clouds at 286 pc.

In Figure 3.9 the two nearest stars with a considerable extinction are: No. 1188 of spectral type K1 IV with d = 183 pc and A_V = 0.96 mag, and No. 678 of spectral type K2.5 V with d = 245 pc and A_V = 1.98 mag. Their mean apparent distance is 214 pc. Considering that these stars have negative absolute magnitude errors ΔM_V = –0.5, we obtain the cloud distance at 214/0.8 = 268 pc with a 3σ error of $\pm$55 pc. The 1σ error should be close to $\pm$ 20 pc.

Another estimate of the distance to the clouds can be done considering the largest apparent distances of stars with a small or zero extinction. If these stars have positive distance errors, then the true cloud distance is $d = d\,(\mathrm{back}) - 0.2\,d$, or $d = d\,(\mathrm{back}) \times 0.8$. The most distant star with a low extinction is No. 496 of spectral type G0 V at d = 380 pc and A_V = 0.17 mag. If we consider this star having a positive absolute magnitude error ΔM_V = +0.5, the cloud distance should be at 380 $\times$ 0.8 = 304 pc. Probably, the true distance of the cloud is somewhere between the two

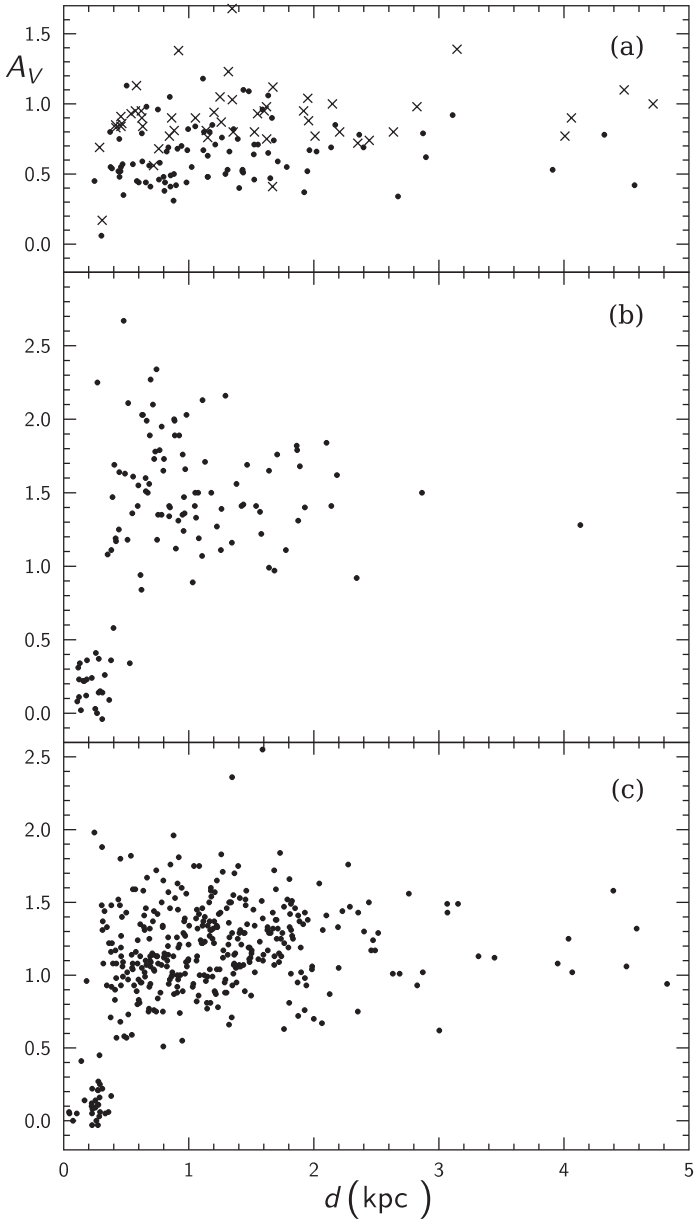

Figure 3.10.: Dependence of the extinction A_V on distance for the TGU 619 areas delineated in Figure 3.8: (a) – two most transparent subareas (dots for T_1 and crosses for T_2), (b) – the darkest subarea D, (c) – the remaining stars of the area.

estimated values, i.e., at (268 + 304)/2 = 286 pc, with $1\sigma = \pm 20$ pc.

The investigated area is quite heterogeneous with respect to the amount of the extinction. This is well seen in the SkyView blue and red DSS2 charts with the increased contrast, as well as in the Dobashi et al. (2005) atlas. In Figure 3.8 we delimited three subareas – two most transparent regions in the upper part of the area, and the area containing dust clumps of the TGU 619 cloud. Panels (a) and (b)

in Figure 3.10 show the dependence of A_V on d in these subareas. All the remaining stars, located in the regions of intermediate extinction, are plotted in panel (c).

No significant differences in the distance in these four subareas can be noticed. Also, the additional jump of the extinction at d = 715 pc, found in the direction of NGC 7023 (Zdanavičius et al. 2009a), does not appear in the direction of the TGU 619 cloud. The largest extinction found in the direction of this cloud is close to 3 mag, but this is not a real maximum value since the stars with larger extinctions are absent in our sample due to the limiting magnitude effect.

3.3. Parameters of the clusters NGC 7129 and NGC 7142

3.3.1. Distance of the cloud TGU 645 and the cluster NGC 7129

Since the cluster NGC 7129 is embedded in the dust cloud, for the determination of the cluster distance we have applied the method which uses the rise of extinction of the field stars located at a distance of the dust cloud.

For the determination of the extinction run with distance in the direction of NGC 7129, 72 stars from Table B.3 with the most accurate spectral types were used. This sample was supplemented with 83 stars classified with good accuracy in Table B.4 and located outside the $13' \times 13'$ area but inside the $20' \times 20'$ area centered on the cluster. This area covers the whole molecular cloud around NGC 7129 shown in the CO map by Ridge et al. (2003). The known YSOs and other stars with low classification accuracy were excluded.

Fig. 3.11 shows the extinctions A_V plotted as a function of the distance d. The error bar in distance corresponds to $\Delta M_V = \pm 0.5$ mag, a typical 3σ error of absolute magnitudes estimated from photometric spectral types. The errors of A_V, originating from the observational errors and intrinsic 'cosmic dispersion' of the relation between Y–V and spectral classes, are of the order of ± 0.2 mag.

The distribution of stars in Fig. 3.11 shows that the extinction increases steeply close to $d \approx 1$ kpc where the TGU H645 P2 cloud can be located. The scatter of A_V at greater distances is quite large – from about 1 mag to 3.4 mag. Another, much lower rise of extinction up to 1 mag might be present at a distance of ~ 500 pc.

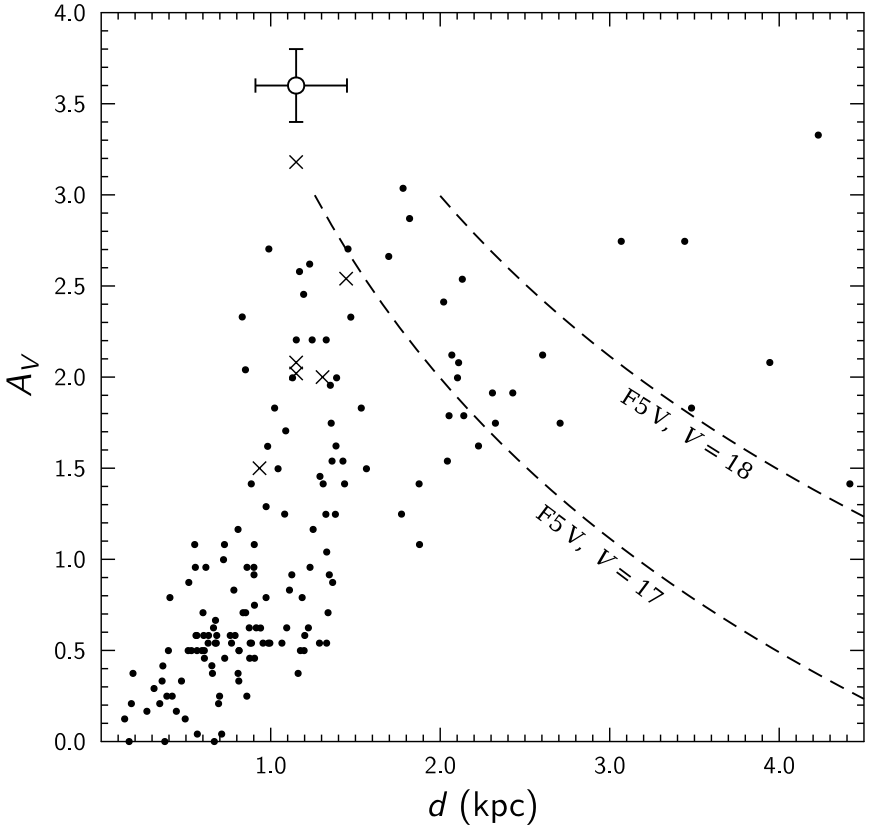

Figure 3.11.: Extinction vs. distance diagram for stars of the NGC 7129 area classified in the Vilnius system. The two curves show the limiting magnitude effect for F5 V stars at V = 17 and 18 mag.

For determining the cloud distance we must take into account that a portion of stars are scattered toward lower distances because of negative distance errors. The main source of distance errors is in their absolute magnitudes – in the photometric classification we take ± 0.5 as the 3σ error of M_V. In this case the stars with the maximum negative distance errors will appear closer to the Sun by a factor of 1.26. Thus, if we find stars with large extinctions at a distance d_1 pc, the true distance of the cloud should be at $d = 1.26\,d_1$. In Fig. 3.11 the mean distance of five front stars with $d < 1.0$ kpc and $A_V > 1.4$ mag is 0.91 kpc. If these stars are moved from the dust cloud shorward because of absolute magnitude errors, the front edge of the cloud is expected to be located at d = 1.15 kpc, which corresponds to the true distance modulus V–M_V = 10.30 mag.

Also, for the shortward scattering of apparent distances the unresolved binary stars can be responsible. If both components of a binary star are of the same lumi-

nosity, its real distance should be at $1.41\,d_1$. In this case the distance of the cloud should be at d = 1.28 kpc. Since we have no information that any of the five stars closer than 1 kpc is a binary, we will accept that their shifts shortward are due to the error of M_V only. If this assumption is correct, the absolute distance error (3σ) of the cloud is 240 pc, or $\sigma \approx 80$ pc. At a distance of 1.15 kpc the angular diameter of the cloud, 0.3°, is equal to 6 pc.

The greatest number of stars in the NGC 7129 area with two-dimensional spectral types falls on 17–18 mag. Most of them are main-sequence stars of spectral classes F and G. The two broken curves in Fig. 3.11 demonstrate the effect of limiting magnitude for F5 V stars with magnitudes V at 17 and 18. Above the last curve only B- and A-type stars, as well as G-K-M giants can be found. These types of stars in this area are rare.

Fig. 3.11 shows that behind the dust cloud at 1.15 kpc the extinction does not increase – it remains approximately between 1.5 and 3.4 mag up to 4.5 kpc. This fact is expected, since at the Galactic latitude 9° our line of sight at 2 kpc reaches 320 pc above the Galactic plane, where dust clouds are quite rare. However, the J–H vs. H–K_s diagram of 2MASS shows (Fig. 3.13) that the background RCGs, located at distances from 3 to 8 kpc, are affected by reddening, which corresponds to A_V up to $\sim$14 mag. The most reddened 11 RCGs with J–$H > 1.5$ all are seen mostly in the eastern (left) half of the area with the largest dust density. The presence among them of a few ordinary K–M giants will not change the conclusion that the total extinction, created by the cloud in some directions, is as large as 10–14 mag.

Since the cluster NGC 7129 is embedded in the dust cloud TGU H645 P2, we accept the same distance both for the cloud and the cluster. We have identified only six stars close to the ZAMS for which the membership to the complex is evidenced by illumination of the surrounding dust and forming the reflection nebulae. Three of these stars, Nos. 96, 105 and 154, are 4–6′ away from the central concentration of visible and infrared objects. However, they all are located in the same dust and molecular cloud, and we will consider these three stars as the cluster members formed in the local condensations of gas and dust a few million years ago. The most active formation of stars continues now in the core of the cluster which according to Gutermuth et al. (2004, 2005) has a diameter of 3′, while the whole area in which YSOs are observed, is about 4 times larger.

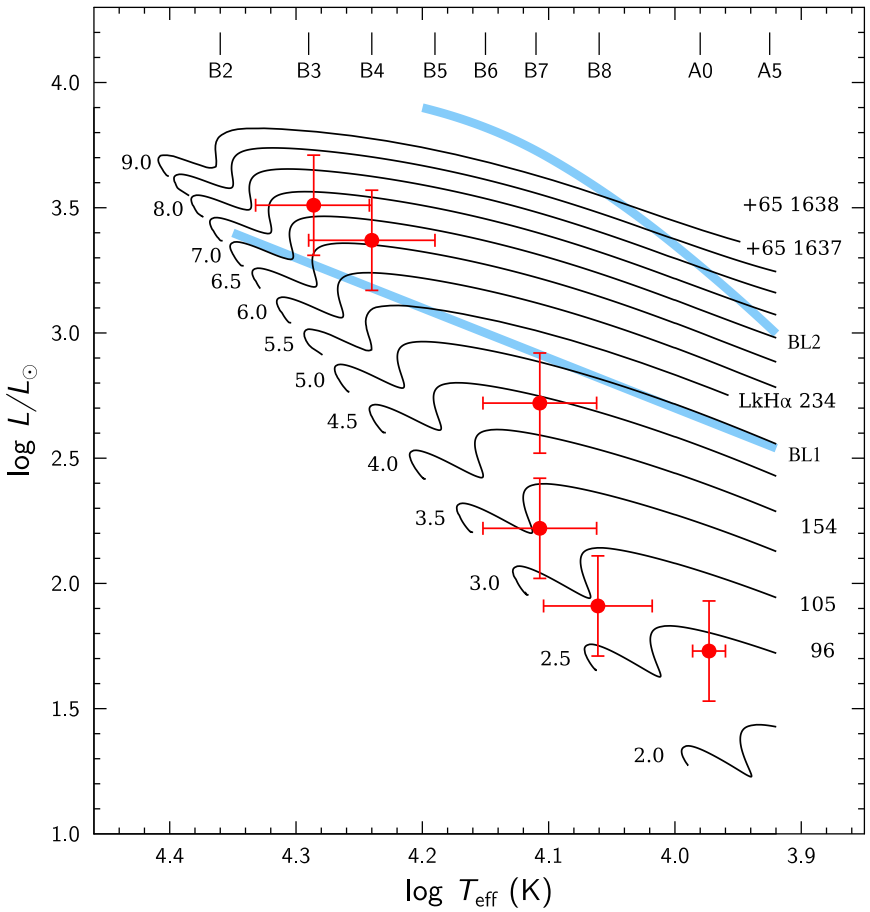

Figure 3.12.: The effective temperature vs. luminosity diagram with the evolution tracks for the masses 2–10 $M_\odot$. Six NGC 7129 members of spectral classes B3–A1 located close to the ZAMS line with theit error bars are plotted in red. The numbers of stars are shown at the right edge of the plot. Spectral classes, corresponding to the effective temperatures, are indicated at the top. The two birthlines for the 10^{-5} and $10^{-4}\,M_\odot\,\mathrm{yr}^{-1}$ accretion rates from Palla (2005) are shown in blue. They are named BL1 and BL2, respectively.

The data for the six cluster stars are given in Table 3.1. Fig. 3.12 shows the plot of these stars in the the $\log L/L_\odot$ vs. $\log T_{\rm eff}$ diagram. Their luminosities in solar units were calculated with the equation

$$\log L/L_\odot = 0.4(M_{\rm bol,\odot} - M_{\rm bol,\star}) = 0.4(4.72 - V + A_V + 10.30 - BC), \qquad (3.4)$$

where V is the apparent magnitude of the star, $M_{\rm bol,\star}$ is its absolue bolometric magnitude, $M_{\rm bol,\odot}$ = 4.72 is the bolometric absolute magnitude of the Sun, BC are the bolometric corrections, and 10.30 is the true distance modulus of the cluster. The extinctions A_V were determined with Eq. (3.1).

Table 3.1.: Photometric and evolution parameters of the most luminous stars in the NGC 7129 area, located in the luminosity-temperature diagram close to the main sequence. The results for the first three stars are based on the MK types and *BV* photometry from Racine (1968), Herbst & Shevchenko (1999) and Hernández et al. (2004), see the text.

No.	Sp. type	V	$\log L/L_\odot$	$\log T_{\rm eff}$	BC mag	Mass $M_\odot$	Age Myr	Notes

Notes.
1. Herbig Ae/Be star; measured in the Vilnius system in Table A.3 (No. 108).
2. YSO of Class III, X-ray source (Stelzer & Scholz 2009).
3. Herbig Ae/Be star; measured in the Vilnius system in Table A.2 (No. 699).

The three brightest stars in the cluster are BD+65 1637 (Herbig Ae/Be star), BD+65 1638 (YSO of Class III) and LkHα 234 (also Herbig Ae/Be star). To calculate the $V_0 = V - A_V$ and $(Y–V)_0$ values of these stars, the following spectral classes were used: B3 for BD+65 1638 from Racine (1968), B4 for BD+65 1637 and B7 for LkHα 234, both from Hernández et al. (2004). The last two stars are variables (V361 Cep and V373 Cep) with the V amplitudes 0.71 and 1.48 mag, respectively. Their positions in Fig. 6 were calculated using the average V magnitudes and B–V colors from Herbst & Shevchenko (1999). For BD+65 1638 the extinction was calculated from *BV* photometry given by Racine (1968). If we place these three stars at the accepted distance of the cloud (1.15 kpc), their absolute magnitudes and corresponding luminosity classes are as follows: –2.20 (B3 IV) for BD+65 1638, –2.14 (B4 III-IV) for BD+65 1637, and –1.27 mag (B7 III) for LkHα 234.

The three fainter stars, No. 96 (2MASS J21424031+6610069, A1 IV-V), No. 105 (2MASS J21424707+6610512, B8 V) and No. 154 (2MASS J21435035+6608477, B7 V), plotted in Fig. 3.12, are the sources illuminating the dust cloud in their vicinities and forming the three small reflection nebulae around them. The first two stars were observed in the *JHKL* system by Strom et al. (1976) (SVS 2 and SVS 10). The reflection nebulae around them are described by Magakian & Movsesian (1997). The star No. 96 was identified by Stelzer & Scholz (2009) as YSO with X-ray emis-

sion. The stars Nos. 96 and 105 show the excess emission in the WISE 12 and 22 μm bands. However, both of them have approximately photospheric spectral energy distributions up to λ = 5–8 μm. A possibility exists that the flux measurements of these stars in the longest WISE bands are affected by a strong background of the surrounding nebula (see the WISE images of NGC 7129 in SkyView and the discussion in Koenig et al. (2012).

The bolometric corrections and temperatures of stars were taken from Straižys (1992) according to their spectral classes. Our scale of $T_{\rm eff}$ for B-stars is close to that given by Flower (1996), Bessell et al. (1998) and Torres (2010).

The PMS evolution tracks for 2–9 $M_{\odot}$ stars of solar chemical composition (Z = 0.0129, Y = 0.2740, ML = 1.74, $X_D = 2 \cdot 10^{-5}$,) were taken from the database of Pisa Stellar Models calculated by P. G. Prada Moroni especially for this investigation. More details about the tracks can be found in Tognelli et al. (2011).

The positions of the six stars with respect to the evolution tracks allow to estimate their masses and ages, the results are given in Table 3. Among the six stars, BD+65 1638 has the largest mass (about 7.2 $M_{\odot}$) and is the youngest (200 000 yr). The star No. 96 has the smallest mass (2.5 $M_{\odot}$) and is the oldest (3.1 Myr). The error crosses for each star are shown. The errors of $\log L/L_{\odot}$ correspond to the absolute (3σ) errors of the accepted distance modulus of the cluster, $\pm\,0.5$ mag. The errors $\log T_{\rm eff}$ correspond to an error of $\pm\,1$ decimal spectral subclass. Naturally, for the two Ae/Be stars the real errors should be larger due to lower accuracy of spectral classification, variability, presence of circumstellar disks and envelopes, possibility of anomalous extinction law in the circumstellar dust, etc.

3.3.2. 2MASS two-color diagram for the cluster NGC 7129

Important information about the cluster and its vicinity can be obtained from the near-infrared JHK_s photometry of the 2MASS survey Skrutskie et al. (2006). The diagram J–H vs. H–K_s, together with various two-color diagrams, containing magnitudes of the Spitzer and WISE infrared surveys, have been used to identify tens of YSOs in the cloud (see references in Note table). We will apply this system to verify if the interstellar reddening law in the area is normal.

Fig 3.13 shows the J–H vs. H-K_s diagram for 2MASS stars located in a $15' \times 15'$

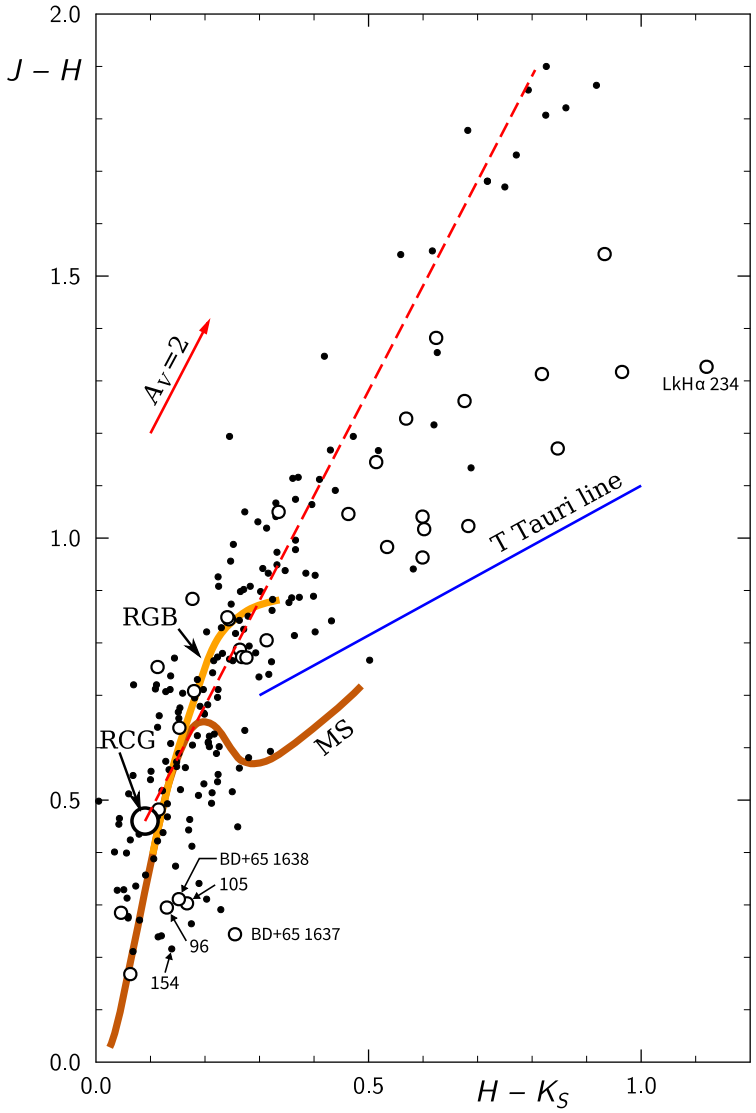

Figure 3.13.: The *J*–*H* vs. H–K_s diagram for the 2MASS stars with errors of magnitudes ≤ 0.05 mag in the $15' \times 15'$ box centered on NGC 7129. Above *J*–*H* = 1.5 the accuracy limit of magnitudes < 0.1 is accepted. The main sequence (MS, brown belt), red giant branch (RGB, orange belt), the intrinsic locus of red clump giants (RCG) with its reddening line, and the intrinsic T Tauri line are shown. The YSOs, listed in Notes to Table A.3, are shown as open circles.

field with the center on NGC 7129. Lower than *J*–*H* = 1.5, only the stars with magnitude errors ≤ 0.05 mag are plotted. The location of intrinsic sequences of luminosity V and III stars and the intrinsic position of the Red Clump Giants (RCGs) are shown according to (Straižys & Lazauskaitė 2009). Trying to plot heavily reddened RCGs, above the mentioned value of *J*–*H*, magnitude errors are allowed up to 0.1 mag. The reddening line with the slope $E_{J-H}/E_{H-K_s} = 2.0$, drawn through their

intrinsic position of RCGs at J–H = 0.46, H–K_s = 0.09 represents well the reddened RCGs up to J–H = 1.9. This slope of the reddening line is typical to most dark clouds and correspond to normal interstellar reddening law (Straižys et al. 2008; Straižys & Laugalys 2008). This, 2MASS photometry shows that the near-infrared interstellar reddening law in the direction of NGC 7129 is close to normal.

The YSOs of NGC 7129 observed in the Vilnius system are plotted in Fig. 3.13 as open circles. YSOs of Class II (T Tauri stars with circumstellar disks) are located above the intrinsic line of T Tauri stars shown in the Figure (from Meyer et al. 1997). YSOs of Class III (diskless objects) are mixed with the normal stars. Many more YSOs have been identified with the Spitzer infrared and the Chandra X-ray surveys, but most of them were not accessible for our CCD photometry in the Vilnius system, being too faint or located in the bright area of the reflection nebula.

3.3.3. Distance and age of the cluster NGC 7142

For determining the distance to NGC 7142 we applied five RCGs identified by Sandquist et al. (2011). The numbers of these stars in Table B.5 are 461, 493, 683, 998 and 1026, all of them are of spectral types G8–G9 III classified with good accuracy. The sixth RCG identified by Sandquist et al., our No. 799, could not be classified since it is a visual binary with the components of similar brightness and a separation of 2–3″. The mean distance to the five RCGs, 2.33 ± 0.14 kpc, was calculated taking their average dereddened magnitude V_0 = 12.54 mag and the absolute magnitude M_V = +0.7 mag, corresponding to G8–G9 giants in the RCG sequence on the M_V vs. B–V diagram for the Hipparcos stars (Perryman et al. 1997). The given rms error originates from the dispersion of dereddened V magnitudes of the five stars.

Table 3.2.: Red clump giants in the cluster NGC 7142.

Number	V	Sp. type	$(Y–V)_0$	A_V	V_0	d (pc)
461	13.72	G8 III	0.72	1.12	12.60	2400
493	13.50	G9 III	0.75	1.16	12.34	2130
683	13.78	G8 III	0.72	1.29	12.49	2280
998	13.76	G9 III	0.75	1.21	12.55	2340
1026	13.95	G8 III	0.72	1.21	12.74	2560

The A_V vs. d diagram for 507 stars in the direction of NGC 7142, derived from the data of Table B.5, is shown in Fig. 3.14. It includes the both –field stars and the cluster members. At low distances the extinction A_V increases gradually up to 1.0–1.2 kpc reaching the values between 0.8 and 1.5 mag. At this distance range the line of sight should cross the outskirts of the dust cloud TGU H645 P2 in which the nearby young cluster NGC 7129 is embedded. At larger distances no extinction rise is expected since at this Galactic latitude our line of sight recedes from the Galactic dust layer near its plane. At a distance of 1.2 kpc the line of sight is already 200 pc above the plane.

In the calculation of the individual distances to the RCGs we applied their absolute magnitude M_V = +0.7, read out for the G8–G9 giants from the M_V vs. B–V diagram of the Hipparcos stars (Perryman et al. 1997). In this diagram the absolute magnitudes are calculated from the parallaxes of high accuracy. The calculated distances of individual RCGs are listed in Table3.2 The average distance is 2310 pc.

Distances to the same RCGs can be also determined from 2MASS JHK_s photometry accepting to the stars the absolute magnitudes M_{K_s} = –1.6 (Alves 2000; Grocholski & Sarajedini 2002) and the intrinsic color indices H–K_s = 0.09 (Straižys & Lazauskaitė 2009). The mean distance of these stars, 2270 pc, is in good agreement with the result from Vilnius photometry.

Except of the five RCGs, we also attribute to cluster members a few red giants of spectral class K for which the membership was inferred from radial velocities. The three reddest giants of spectral types K2–K4.5 with numbers 1077, 1102 and 1181 were taken from the Table A.2. A few G-K giants and subgiants were added to the list of members according to their position in the dereddened CMD and the distance, with possible errors of M_V taken into account.

Thus, we accept that the cluster is located close to 2.3 kpc. This more or less is in agreement with the more distant star density maximum seen in Fig. 3.14 At this distance the diameter of the cluster is: $2300 \times \mathrm{tg}\, 0.2^\circ \approx 8$ pc. Thus, the whole spread of stars seen in Fig. 3.14 is a consequence of the distance determination errors. The error of absolute magnitude $\pm\, 0.5$ mag at a distance of 2.3 kpc gives the spread of apparent (i.e., not real) distances between 1.8 kpc and 2.9 kpc. The 194 stars found within these two distances and the extinctions A_V between 0.7 and 1.5 mag were accepted to be possible cluster members. Naturally, a certain amount of field stars

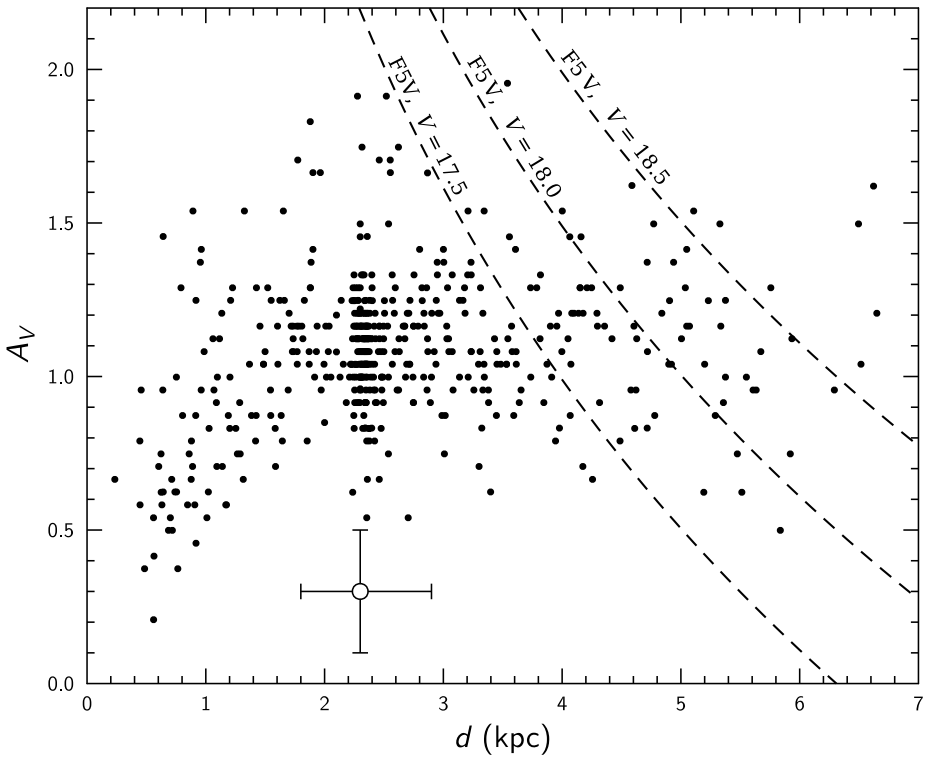

Figure 3.14.: Extinction vs. distance diagram for the stars of the NGC 7142 area classified in the Vilnius system. The two curves show the limiting magnitude effect for F5 V stars at V = 17 and 18 mag.

in this distance range is expected.

In the intrinsic CMD (Fig. 3.15) a strong crowding of stars is seen near the main sequence with $(Y-V)_0$ from 0.46 to 0.53, corresponding to the spectral classes F5–G0 and the luminosity classes V–IV. This signifies the presence here of the cluster stars near the turn-off point. We have accepted that all these crowding stars are cluster members since the main sequence in the direction of higher temperatures is almost empty (except of a few possible blue stragglers).

Unfortunately, in this spectral range the luminosity effect between V and IV classes on Q-parameters is quite small, and most stars located close to the turn-off point during photometric classification have been attributed to luminosity V. However, in the intrinsic CMD many of them lie at different levels above ZAMS, consequently, they should be of a higher luminosity. To make the absolute magnitudes closer to reality, we took into account their rise in the CMD diagram above the ZAMS line, ΔV, which was subtracted from M_V of the ZAMS. This procedure was not applied only to the stars located ± 0.2 mag from the ZAMS – these stars were

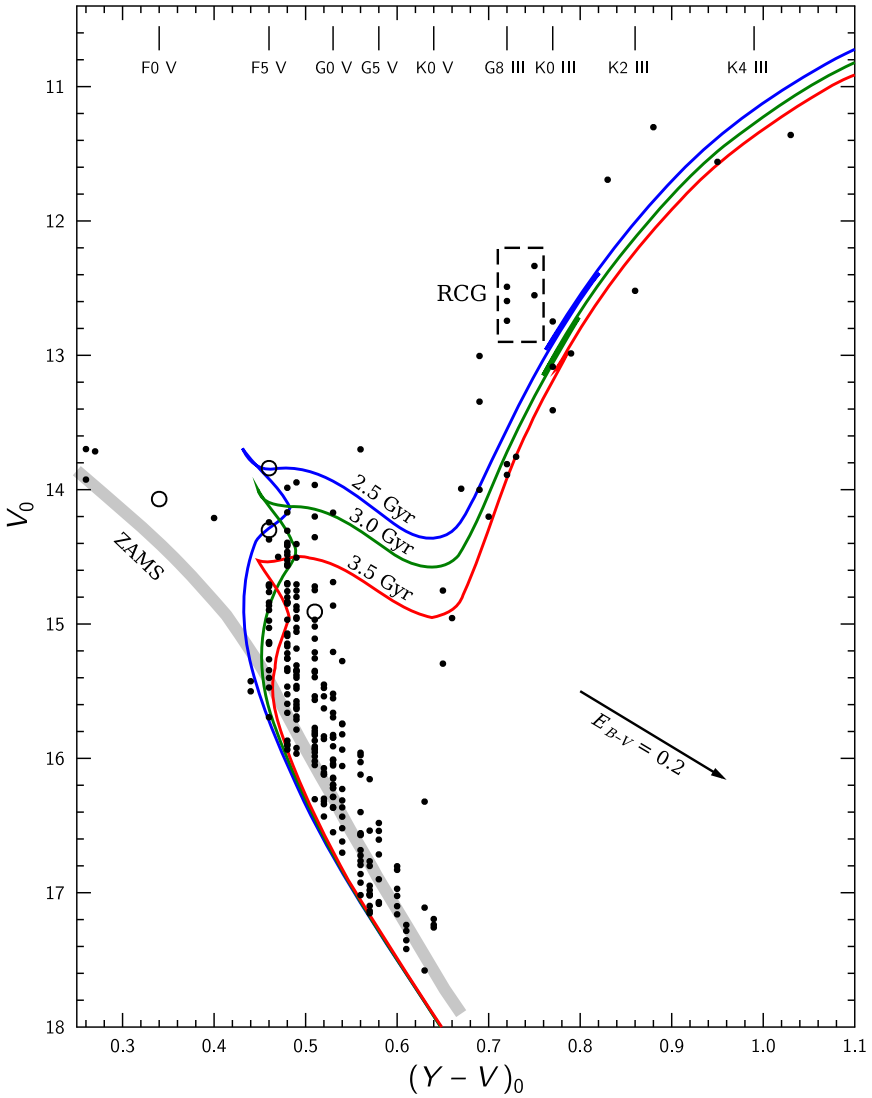

Figure 3.15.: Dereddened colour-magnitude diagram for 255 possible members of the cluster NGC 7142. The grey line is the ZAMS from Kazlauskas et al. (2006) and the three coloured lines are the Padova isochrones for the ages 2.5, 3.0 and 3.5 Gyr, all are shifted according to a distance modulus of V_0–M_V = 11.8. Spectral classes, corresponding to the intrinsic $(Y-V)_0$ colours, are indicated at the top. The five possible RCG stars are placed in a rectangular box. Some amount of field stars can be present in the diagram. The four eclipsing variables, probable non-members, are shown as open circles.

accepted to belong to luminosity V. In this way more negative absolute magnitudes were found for many stars in the region of the turn-off point. Since some stars in this region of CMD are binaries, their luminosities determined by this method should be overestimated. This must be taken into account determining the age of the cluster.

The choice of the coolest stars at spectral class G0, to which the absolute mag-

nitudes have been corrected with the described method, is somewhat voluntary. It is based on the fact that for G-type stars the photometric luminosity effect is larger, and the stars are classified in luminosity classes with a better reliability.

The grey line in Fig. 3.15 represents the ZAMS for solar metallicity from Kazlauskas et al. (2006) corresponding to the distance modulus V_0–M_V = 11.8 mag. The main sequence of the cluster has the turn-off point at $(Y–V)_0$ = 0.46, spectral type F5 V. The spread of stars in absolute magnitudes at this point is about 1.5 mag. About 15 stars are located close to the expected sequence of giants and subgiants. Five possible blue stragglers (their numbers in Table B.5: 337, 418, 631, 664 and 754, spectral classes A6–F2) are seen close to the ZAMS. Due to possible duplicity, their positions in the colour-magnitude diagram can be of lower accuracy. One of them, No. 631 (F0 V) is an eclipsing variable V3 from the Sandquist et al. (2011) list. Two K-stars, Nos. 348 (K2.5 III) and 820 (K1.5 III) can belong to the asymptotic giant branch.

The intrinsic CMD of the cluster can be used for its age determination comparing to isochrones, but for this the metallicity should be known. From photometric diagrams in the Washington system, [Fe/H] = –0.17 was found by Geisler et al. (1991). From the medium-resolution spectroscopy of 11 red giants Friel & Janes (1993) found the mean metallicity [M/H] = 0.0 from the Fe and Fe-peak element blends and –0.23 from the Mgb+MgH feature. Twarog et al. (1997) transformed these values to a revised metallicity scale and received a value of [Fe/H] = +0.04. Jacobson et al. (2007, 2008) from medium- and high-resolution spectra of six stars have found [Fe/H] = +0.08 and +0.14. Sandquist et al. (2013) from high-resolution spectra of the eclipsing variable V375 Cep have found [Fe/H] = +0.09. Thus for the age determination we decided to use the isochrones for [Fe/H] = +0.10 which corresponds to Z = 0.019.

In Fig. 3.15 we plot three isochrones for the ages 2.5, 3.0 and 3.5 Gyr from the Padova database of stellar evolutionary tracks and isochrones[1] for the Vilnius system adjusted to a distance modulus of 11.8 mag. It is evident that the main-sequence lines of the isochrones with respect to the observed ZAMS line show a shift down by 0.2 mag in absolute magnitudes *or* by 0.02 mag to the left in $Y–V$. It is difficult to determine the reason of this shift; it can be the result both of the observational ZAMS

[1] Bressan et al. (2012) and http://stev.oapd.inaf.it/cgi-bin/cmd

and the theoretical isochrones. The problems of the transformation of isochrones to the observational plane were discussed in many papers, see e.g. van den Berg et al. (2010) and Sandquist et al. (2011).

A visual comparison of the distribution of stars near the turn-off point with isochrones shows that the cluster age should be somewhere between 2.5 and 3.0 Gyr. In the region of red giants, the 3.0 Gyr isochrone seems to be preferable. However, if we shift the isochrones by 0.2 mag upward (up to the coincidence with the observed ZAMS), then the 3.0 and 3.5 Gyr isochrones become favoured. Also, if the four stars at the hook of the upper isochrone between V_0 = 13.8 and 14.0 mag are binaries or non-members, the 3.0 Gyr isochrone would well represent its hook stars at 14.2–14.4 mag. The bluest star on the 2.5 isochrone, No. 239 (V1, F5 V), is really the binary, eclipsing variable and probable non-member (Sandquist et al. 2011, 2013). Consequently, there are good reasons to consider that the age of NGC 7142 is close to 3.0 ± 0.5 Gyr.

The vertical bar of stars in Fig. 3.14 at d = 2.3 kpc and A_V between 0.8 and 1.35 mag is formed by the cluster members, mostly by F5-G0 stars for which the absolute magnitudes were calculated.

In the area, the maximum number of stars with two-dimensional spectral types falls on 17–18 mag. Most of them are main-sequence stars of spectral classes F and G. The three broken curves in Fig. 3.14 demonstrate the effect of limiting magnitude for F5 V stars with magnitudes V between 17.5 and 18.5. Above the upper curve, only B- and A-type stars, as well as G-K-M giants can be found. These types of stars are rare in this area.

Chapter 4

Results and discussion

4.1. Reflection nebula NGC 7023

The dust cloud TGU 629, surrounding the reflection nebula NGC 7023, belongs to a giant dust and molecular cloud system known as the Cepheus Flare. In the summaries of distance determinations of different objects in this system, Kun (1998) and Kun et al. (2008) came to the conclusion that the system either has a considerable depth or consists of several layers with distances ranging from 200 to 500 pc. Two layers of interstellar gas were found by radio observations by Heiles (1967) in the neutral hydrogen 21 cm line and by Grenier et al. (1989) in the CO molecular lines. Applying the kinematical method to velocity profiles of the lines, Grenier et al. find the approximate distances to the layers: 300 and 800–900 pc.

Our results described in Chapter 3 also give evidence that dust clouds in the vicinity of NGC 7023 concentrate at least in two layers at 282 pc and 715 pc. There is a possibility that the true distances of these cloud layers are not the same throughout the area. However, the number of stars at the extinction jumps in different subareas is too small to be sure that these distance differences are real. The extinction vs. distance plots also allow to suspect that more clouds are present along the line of sight. This is in agreement with the map of the CO intensity distribution (Dame et al. 2001) which evidences that the molecular cloud structure in the Cepheus Flare is quite clumpy and fragmented.

Our estimates of cloud distances are in satisfactory agreement with those found by Grenier et al. (1989) from kinematics of the CO clouds. The CO radial velocities show that at the Galactic longitude $\ell = 104^\circ$ both clouds are connected by a bridge. The distant CO layer should be more prominent at larger Galactic longitudes, i.e. on the left side of our area (Subareas II, III and, partly, IV). This is in agreement

with our results.

If we accept that dust clouds in this direction reach a distance of 700 pc, the depth of the cloud layer should be about 400 pc. The length of the whole Cepheus Flare cloud system ($\sim 18^\circ$) corresponds to ~ 95 pc at a distance of 300 pc and to ~ 220 pc at a distance of 700 pc. It seems possible that the Cepheus Flare has its extension known as the Polaris Flare (Heithausen et al. 1993; Dame et al. 2001). In this case the whole complex of molecular clouds from ℓ, b = (100°, +14°) to (126°, +30°) has a length of $\sim 30^\circ$ and the projected complex length is from ~ 160 pc at a distance of 300 pc to ~ 375 pc at a distance of 700 pc. The apparent width of the Cepheus and Polaris Flares is only $\sim 8^\circ$, which corresponds to 42 pc at a distance of 300 pc and 100 pc at 700 pc.

The projected length of the cloud system at 700 pc (375 pc) is comparable to the observed depth of the complex (400 pc), i.e., the complex looks like a pancake, and our line of sight runs along its plane. The heights of the two cloud layers above the Galactic plane in the direction of NGC 7023 are 75 pc and 170 pc.

To have the estimates of cloud distances more accurate, one must minimize the errors of absolute magnitudes of the stars which define the jumps in the extinction vs. distance dependence. This can be done either by spectral observations of these stars to verify their spectral and luminosity classes or by determining trigonometric parallaxes. Within a few years, in the case of the success of the *Gaia* mission, the distance problem of these reddened stars will be solved.

4.2. Dark cloud TGU 619

In this investigation are described the results of the investigation of interstellar extinction in the direction of the dark cloud TGU 619 (Dobashi et al. 2005) located in the Cepheus Flare. The distribution of extinction in the ~ 1.5 square degree area is quite complicated – in some directions the extinction is relatively low, with the A_V values of 0.5–1.5 mag even at large distances. In these regions the lower envelope of the star distribution is in agreement with the mean exponential Parenago law for the galactic latitude $b = 15.5^\circ$. In the direction of the TGU 619 clumps the extinction is so large that even in the Palomar atlas no stars are seen. The found maximum value of extinction at 3 mag corresponds only to the edges of the dust cloud which

is found to be at a distance of 286 ± 20 pc. This distance should be somewhat larger if at least one of the three stars, on which the distance is based (Nos. 496, 678 and 1188), is unresolved binary.

In our earlier investigation (Straižys et al. 1992), the distance to the same cloud group was determined by a similar method but using a photoelectric photometry of brighter stars (V between 9 and 12) in a larger area, with the extinction values A_V between 0.45 and 1.5 mag. The obtained distance, 325 pc, was the average value for 10 stars concentrating within 240–380 pc. Since some of these stars can be located behind the clouds, this distance could be overestimated. Only four of these stars are present in our CCD catalog, so the verification of the result of 1992 is problematic. However, both results are within the error box (see also a discussion on the cloud distances by Kun et al. 2008).

No evidences was find for the presence of the second extinction jump (Zdanavičius et al. 2011) at 715 pc, suspected in the direction of NGC 7023 (Zdanavičius et al. 2009a). This our result is in agreement with the velocity distribution of the CO molecular line emission at $\ell = 102.5^\circ$ shown by Grenier et al. (1989), where only the low velocity component is present.

4.3. Open clusters NGC 7129 and NGC 7142

Since the cluster NGC 7129 is embedded in the dust cloud, for the determination of the cluster distance we have applied the method which uses the rise of extinction of the field stars located at a distance of the dust cloud.

For the determination of the extinction run with distance in the direction of NGC 7129, 72 stars from Table B.3 with the most accurate spectral types were used. This sample was supplemented with 83 stars classified with good accuracy in Table B.4 and located outside the $13' \times 13'$ area but inside the $20' \times 20'$ area centered on the cluster. This area covers the whole molecular cloud around NGC 7129 shown in the CO map by Ridge et al. (2003). The known YSOs and other stars with low classification accuracy were excluded.

Fig. 3.11 shows the extinctions A_V plotted as a function of the distance d. The error bar in distance corresponds to $\Delta M_V = \pm 0.5$ mag, a typical 3σ error of absolute magnitudes estimated from photometric spectral types. The errors of A_V, originat-

ing from the observational errors and intrinsic 'cosmic dispersion' of the relation between Y–V and spectral classes, are of the order of ± 0.2 mag.

The distribution of stars in Fig. 3.11 shows that the extinction increases steeply close to $d \approx 1$ kpc where the TGU H645 P2 cloud can be located. The scatter of A_V at greater distances is quite large – from about 1 mag to 3.4 mag. Another, much lower rise of extinction up to 1 mag might be present at a distance of ~ 500 pc.

For determining the cloud distance we must take into account that a portion of stars are scattered toward lower distances because of negative distance errors. The main source of distance errors is in their absolute magnitudes – in the photometric classification we take ± 0.5 as the 3σ error of M_V. In this case the stars with the maximum negative distance errors will appear closer to the Sun by a factor of 1.26. Thus, if we find stars with large extinctions at a distance d_1 pc, the true distance of the cloud should be at $d = 1.26\, d_1$. In Fig. 3.11 the mean distance of five front stars with $d < 1.0$ kpc and $A_V > 1.4$ mag is 0.91 kpc. If these stars are moved from the dust cloud shortward because of absolute magnitude errors, the front edge of the cloud is expected to be located at $d = 1.15$ kpc, which corresponds to the true distance modulus V–$M_V = 10.30$ mag.

Also, for the shortward scattering of apparent distances the unresolved binary stars can be responsible. If the both components of a binary star are of the same luminosity, its real distance should be at $1.41\, d_1$. In this case the distance of the cloud should be at $d = 1.28$ kpc. Since we have no information that any of the five stars closer than 1 kpc is a binary, we will accept that their shifts shortward are due to the error of M_V only. If this assumption is correct, the absolute distance error (3σ) of the cloud is 240 pc, or $\sigma \approx 80$ pc. At a distance of 1.15 kpc the angular diameter of the cloud, 0.3°, is equal to 6 pc.

The greatest number of stars in the NGC 7129 area with two-dimensional spectral types falls on 17–18 mag. Most of them are main-sequence stars of spectral classes F and G. The two broken curves in Fig. 3.11 demonstrate the effect of limiting magnitude for F5 V stars with magnitudes V at 17 and 18. Above the last curve only B- and A-type stars, as well as G-K-M giants can be found. These types of stars in this area are rare.

Fig. 3.11 shows that behind the dust cloud at 1.15 kpc the extinction does not increase – it remains approximately between 1.5 and 3.4 mag up to 4.5 kpc. This

fact is expected, since at the Galactic latitude 9° our line of sight at 2 kpc reaches 320 pc above the Galactic plane, where dust clouds are quite rare. However, the *J*–*H* vs. H–K_s diagram of 2MASS shows (Fig. 3.13) that the background RCGs, located at distances from 3 to 8 kpc, are affected by reddening, which corresponds to A_V up to $\sim$14 mag. The most reddened 11 RCGs with J–$H > 1.5$ all are seen mostly in the eastern (left) half of the area with the largest dust density. The presence among them of a few ordinary K–M giants will not change the conclusion that the total extinction, created by the cloud in some directions, is as large as 10–14 mag.

In the literature, there are a few estimates of the age of the NGC 7129 stars based on different methods. One of the methods is the estimation of the fraction of stars with the circumstellar disks (YSOs of class II) among the total cluster members. According to Gutermuth et al. (2004) this fraction is 54%, while Stelzer & Scholz (2009) find 33%. Comparing these fractions with the results for other young clusters, they estimate the age of NGC 7129 as 2–3 Myr and 3 Myr, respectively.

Hernández et al. (2004), among other Herbig Ae/Be stars, have obtained new estimates of spectral classes for BD+65 1637 and LkHα 234. Combining these spectral classes with photometry from the literature, they found the positions of these stars in the $\log L/L_\odot$ vs. $\log T_{\rm eff}$ diagram and, comparing with the PMS evolution tracks, estimated their masses and ages. The masses of these stars are 7.0 and 4.8 $M_\odot$, and the ages are are 0.29 and 0.83 Myr, respectively, in close agreement with our results, see Table 3.1.

Kun et al. (2009), using their spectral classes and *BVRI* photometry in NGC 7129, have plotted in the $\log L/L_\odot$ vs. $\log T_{\rm eff}$ diagram four NGC 7129 K–M stars of low masses. Three of them are found to be younger than 1 Myr. Increasing the distance from their 0.8 kpc to our 1.15 kpc leads to the increase the age but insignificantly. However, the observed magnitudes, colour indices and bolometric corrections of YSOs are usually affected by emission lines and infrared excesses, therefore the calculation of their positions in the theoretical HR plane can be inaccurate.

According to the concept of Stahler (1983) (see also Stahler & Palla (2005) and Palla (2005)), all PMS tracks in the HR diagram should begin from a 'birthline' where the new-born stars first appear as visible objects. In the region of masses larger than 1 $M_\odot$ this line runs approximately along the 0.5–1.0 Myr izochrones approaching the ZAMS. The birthline intersects ZAMS at about 7 $M_\odot$ for the ac-

cretion rate $10^{-5}\,M_{\odot}\,\mathrm{yr}^{-1}$ and at about $15\,M_{\odot}$ for the accretion rate $10^{-4}\,M_{\odot}\,\mathrm{yr}^{-1}$. Both these birthlines, BL1 and BL2, are plotted in Fig. 3.12 in blue. The positions of BD+65 1637 and BD+65 1638 are close to the birthline L1 but are slightly above it. For the variable Ae/Be star BD+65 1637 this difference can be related to the errors in its luminosity. However for another star, BD+65 1638, the distance from the birthline BL1 is definitely larger than the luminosity error bar. Probably, this star (or both of them) during the PMS evolution had the accretion rate by a factor of ~ 3 higher than $10^{-5}\,M_{\odot}\,\mathrm{yr}^{-1}$.

About a decade ago Bica et al. (2003) have published a list of star groups which in the atlas of the infrared 2MASS survey look like open clusters. One of these 'infrared groups', [BDS2003] 31, is located close to NGC 7129, with the center coordinates RA = $21^{\mathrm{h}}42^{\mathrm{m}}00^{\mathrm{s}}$, DEC = $+66^{\circ}05'12''$ Fig. 4.1. It is evident that this group is not an infrared object since its 12 stars, seen in the K_s filter, are all observable in optical wavelengths.

Most of these stars were measured in the Vilnius system (Table B.7) and classified in two dimensions. We plotted for the group the A_V vs. d and the V_0 vs. $(Y–V)_0$ diagrams. Both these plots do not confirm that these stars form a real cluster: their A_V are scattered within 0.3–1.8 mag, distances are within 0.4–5 kpc, and in the colour-magnitude diagram no sequence is seen.

In the present investigation we find the following parameters of NGC 7142: the mean extinction A_V = 1.1 mag (corresponding to E_{B-V} = 0.35), the distance 2.3 kpc (the true distance modulus 11.8) and the age close to 3.0 Gyr. The value of the distance is not completely independent, since it is based on the five RCGs identified by Sandquist et al. (2011) and confirmed in the present paper. The parameters of the cluster are in a good agreement with the Sandquist et al. results based on *BVI* and partly on *JHK* photometry. However, in our case the results are obtained in a completely different system which allowed us to classify stars in spectral and luminosity classes and apply their individual dereddening. Therefore the resulting parameters of the cluster should be more reliable.

In most investigations the parameters of NGC 7142 are compared with the parameters of other old metal-rich clusters, mostly with M67. According to the latest estimates (Salaris et al. 2004; Cheng et al. 2012), the age of M67 is 4.3 Myr, i.e. it is somewhat larger than our value for NGC 7142. Since the reddening of M67 is

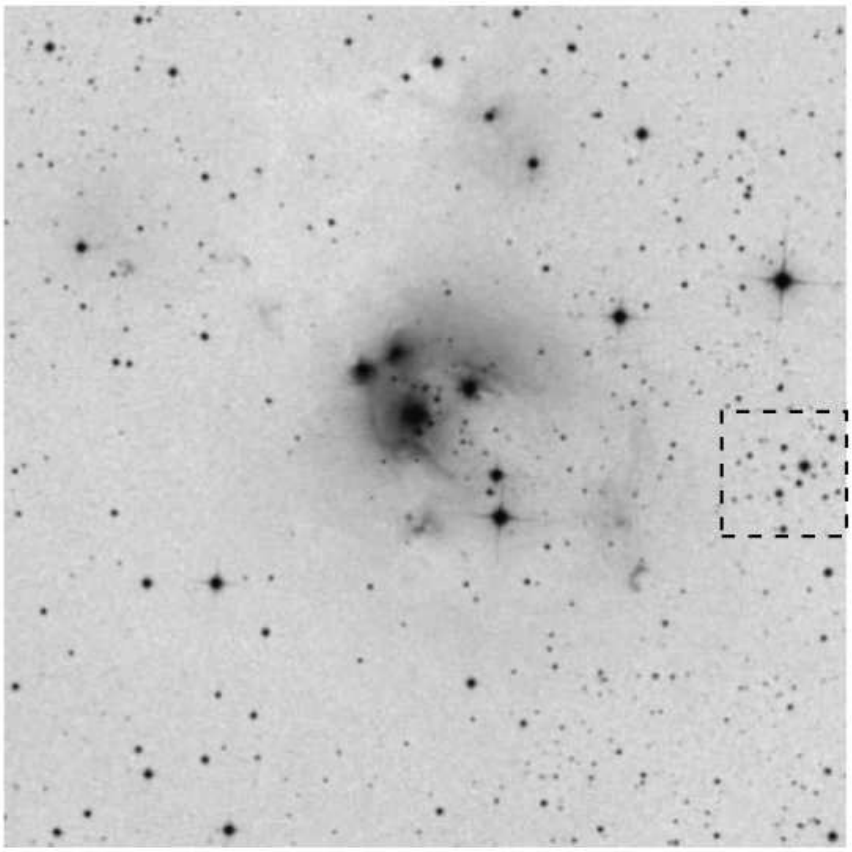

Figure 4.1.: Area of the cluster NGC 7129 observed in the Vilnius photometric system with VATT (13 $\times$ 13). The 2 $\times$ 2 square surrounds a group of stars which was suspected by Bica et al. (2003) as an infrared cluster. The DSS2 Red map from SkyView.

small and well known, and the NGC 7142 stars in our study are individually dereddened, we may directly intercompare intrinsic colour indices of stars at the turn-off points. In our earlier study (Boyle et al. 1998) it was found that the turn-off point of M67 is at $(Y-V)_0$ = 0.50, this corresponds to the spectral class close to F8, while in the present paper for NGC 7142 we have this colour at 0.46 and the spectral class at F5. This can be interpreted that M67 is really older because metallicities of both clusters are similar.

Another feature in the colour-magnitude diagram, depending on the age is the presence or absence of stars on the horizontal part of the sequence of subgiants joining the hook above the turn-off point and the lower part of the giant sequence. This sequence in the clusters younger than M67 is located in the lower part of the Hertzsprung gap and is empty. In NGC 7142 such stars are absent too, while in M67 the subgiant sequence is well populated. The stars on the subgiant sequence

of NGC 7142 could not be lost in the dereddening process since the reddening lines in Fig. 3.15 are approximately parallel to this sequence.

Recently, Sandquist et al. (2013) estimated the age of the detached eclipsing binary V375 Cep, a member of NGC 7142, using the masses and radii of the components determined by modelling radial velocity and light curves of the system. The measured mass and radius of the primary component gives an age of 3.3–3.6 Gyr. The lower limit of this age is not very different from our value of 3.0 Gyr, which is also not very accurate due to the input physics computing the isochrones and their transformation to the observational CMD using the theoretical model atmospheres. Sandquist et al. (2013) accepted for the cluster $E_{B-V} = 0.29$, which is by 0.06 mag lower than the mean colour excess of the cluster estimated in the present paper. Unfortunately, the star V375 Cep is absent in our catalogue since its classification and reddening determination were impossible due to its strange color indices. Probably, our CCD frames in different filters have been exposed in different variability phases. We have attempted to estimate the reddening of V375 Cep from colour excesses of the surrounding stars Nos. 407, 425 and 454 located within $25''$ from the variable. However, their A_V are quite different: 1.04, 1.25 and 1.41 mag, respectively. The mean value is A_V = 1.23, which corresponds to $E_{B-V} = 0.39$. In close vicinity of V375 Cep, west of it, a starless patch with a diameter of $1.5'$ is seen which can be an area with a larger dust density. Thus, reddening of this star can be larger than the average. At the same time, we have classified successfully other four eclipsing variables from the Sandquist et al. (2011) list – in Fig. 3.15 they are shown as open circles. Among them No. 631 (F0 V) from Table B.5, a suspected blue straggler, is present.

Chapter 5

Main results and conclusions

1. Interstellar extinction is investigated in a 1.5 square degree area in the direction of the reflection nebula NGC 7023 at RA=21:01:37, DEC=+68:09:48. The study is based on photometric classification and the determination of interstellar extinctions and distances of 480 stars down to V = 16.5 mag from photometry in the *Vilnius* seven-color system. The dust cloud TGU 629, located in the vicinity of the reflection nebula NGC 7023, concentrates at least in two layers at 282 pc ($^{+73}_{-56}$) and 715 pc ($^{+186}_{-143}$).

2. Interstellar extinction is investigated in a 1.5 square degree area in the direction of the dark cloud TGU 619 of the Cepheus Flare at RA=20:40:00, DEC=+67:50:00. The study is based on photometric classification of 658 stars in spectral and luminosity classes down to V = 16 mag. The extinction values vary from 0.3–1.1 mag in most transparent directions, while in the darkest directions the largest extinction observed is 2.6 mag. The real extinction should be considerably larger since in the direction of some cloud clumps no stars are seen. The distribution of stars in the A_V vs. d plot gives evidence that the dust clouds are located at a distance of 286 pc ($^{+74}_{-57}$).

3. The interstellar extinction was investigated in a $20' \times 20'$ area in the direction of the open cluster NGC 7129 in Cepheus. The investigation is based on 155 stars observed and classified in spectral and luminosity classes down to V = 18.0 mag. The distance to the interstellar dust cloud TGU 645, which contains the embedded cluster NGC 7129, is 1150 pc ($^{+293}_{-226}$). The extinction A_V of the cluster area has the values between 0.6 and 2.8 mag. The extinction Av determined from 2MASS JHK photometry gives the values up to 13 mag in the densest part of the cloud.

4. For determining the age of NGC 7129, six cluster members of spectral classes B3 to A1 were plotted in the $\log L/L_\odot$ vs. $\log T_{\rm eff}$ diagram, together with the Pisa

evolution tracks. Masses of the six stars are found between 2.5 and 7.2 $M_{\odot}$ and their ages between 0.2 and 3.1 Myr show the cluster age to be up to 4 Myr.

5. The cluster distance, 2.3 kpc, is estimated using five red clump giants from their photometric data in the Vilnius systems. Taking into account the errors of absolute magnitudes ± 0.5 mag, possible members of the cluster in the range of distances between 1.8 and 2.9 kpc are selected. More members close to the red giant sequence were added from their membership estimations from radial velocities. The total number of the possible cluster members is 255.

6. In NGC 7142, 194 stars with the apparent distances between 1.8 and 2.9 kpc were selected as possible cluster members. Their plot in the dereddened color-magnitude diagram together with the Padova isochrones and the adopted distance modulus 11.8 mag gives the cluster age 3.0 ± 0.5 Gyr.

Acknowledgements

I would like to express my sincere thanks to everybody who assisted me in my doctorate studies and in the preparation of materials for the thesis.

The greatest thanks to my family and especially to my wife Daiva for her understanding, support and patience during long years of my studies.

During all these years I felt a constructive support, which I appreciate very much, of my supervisor Justas Zdanavičius and also a sincere share of knowledge and experience in photometry and classification fields of the consultant Kazimieras Zdanavičius. I still remember very interesting lectures of astronomy during my bachelor studies given by Romualda Lazauskaitė. I am sure that these lectures brought me onto the way of astronomy.

I still remember the astronomy handbook I used during the bachelor studies, one of the authors of this handbook was Vytautas Straižys, and I could not dream at that time that after several years I would be a co-author of the articles, together with this prominent scietist. I am very grateful to Vytautas for his assistance in the data analysis, for sharing his experience and knowledge and help in the preparation of joint articles for publication.

Great thanks to Gražina Tautvaišienė, Stanislava Bartašiūtė, Antanas Bartkevičius and Algirdas Kazlauskas for very interesting and very useful lectures during the years of the doctoral studies.

I would like to express my thanks to Richard P. Boyle for the observational materials obtained at the Vatican Observatory which I used in this study.

I am very grateful to all the authorities and staff of the Institute of Theoretical Physics and Astronomy and to all staff members of the Molėtai Observatory for good working atmosphere and a comprehensive support.

In this study I have used the Simbad, 2MASS, Sky View, Spitzer, Chandra X-ray, WISE and Padova databases, which are also acknowledged.

Appendix A

Photometry of stars

A.1. Photometry of stars in the TGU 619 area

Table A.1
Results of photometry and classification of stars in the TGU 619 cloud area.

A.2. Photometry of stars in the directions of NGC 7129 and NGC 7142

Table A.2

Results of photometry and classification of stars in the direction of NGC 7129 and NGC 7142 area. The stars with two asterisks in the last column were not classified since their images in DSS2 are asymmetrical, i.e., these stars are double or multiple.

A.3. Deep photometry of stars in the NGC 7129 area

Table A.3

Results of photometry and classification of stars in the direction of NGC 7129 area. The stars with two asterisks in the last column were not classified since their images are asymmetrical, i.e., these stars are double or multiple.

A.4. Deep photometry of stars in the NGC 7142 area

Table A.4

Results of photometry and classification of stars in the direction of NGC 7142 area. The stars with two asterisks in the last column were not classified since their images are asymmetrical, i.e., these stars are double or multiple.

Notes:

1. Radial velocities and metallicities determined by Jacobson et al. (2007, 2008);
2. Radial velocities and metallicities determined by Friel et al. (1989) and Friel & Janes (1993);
3. Red clump giants of NGC 7142 (Sandquist et al. 2011 and this paper);
4. Images are asymmetrical or with close neighbours, double or multiple stars;
5. BD+65 1642;
6. Variable (Sandquist et al. 2011, 2013).

Appendix B

Classification of stars

B.1. Classification of stars in the NGC 7023 area

Table B.1

Classification of stars around NGC 7023 area with most reliable spectral types determined from *Vilnius* photometry. The column *p* gives the accuracy estimates of spectral types.

B.5. Classification of stars in the NGC 7142 area

Table B.5

Stars in the NGC 7142 area observed in the Vilnius photometric system with VATT and the most reliable spectral types determined.

Appendix C

Finding charts of stars

Finding charts in the NGC 7023 area

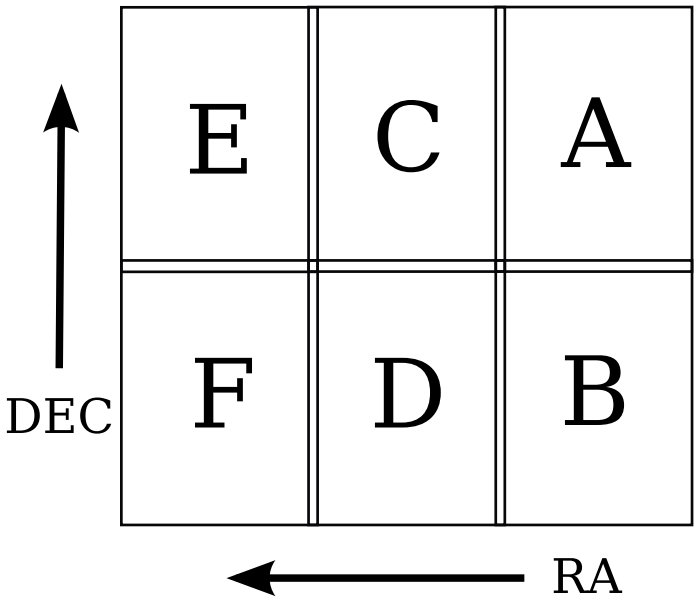

Figure C.1.: Division of the identification chart into six sextions for NGC 7023 area shown in Figures C.2-C.7

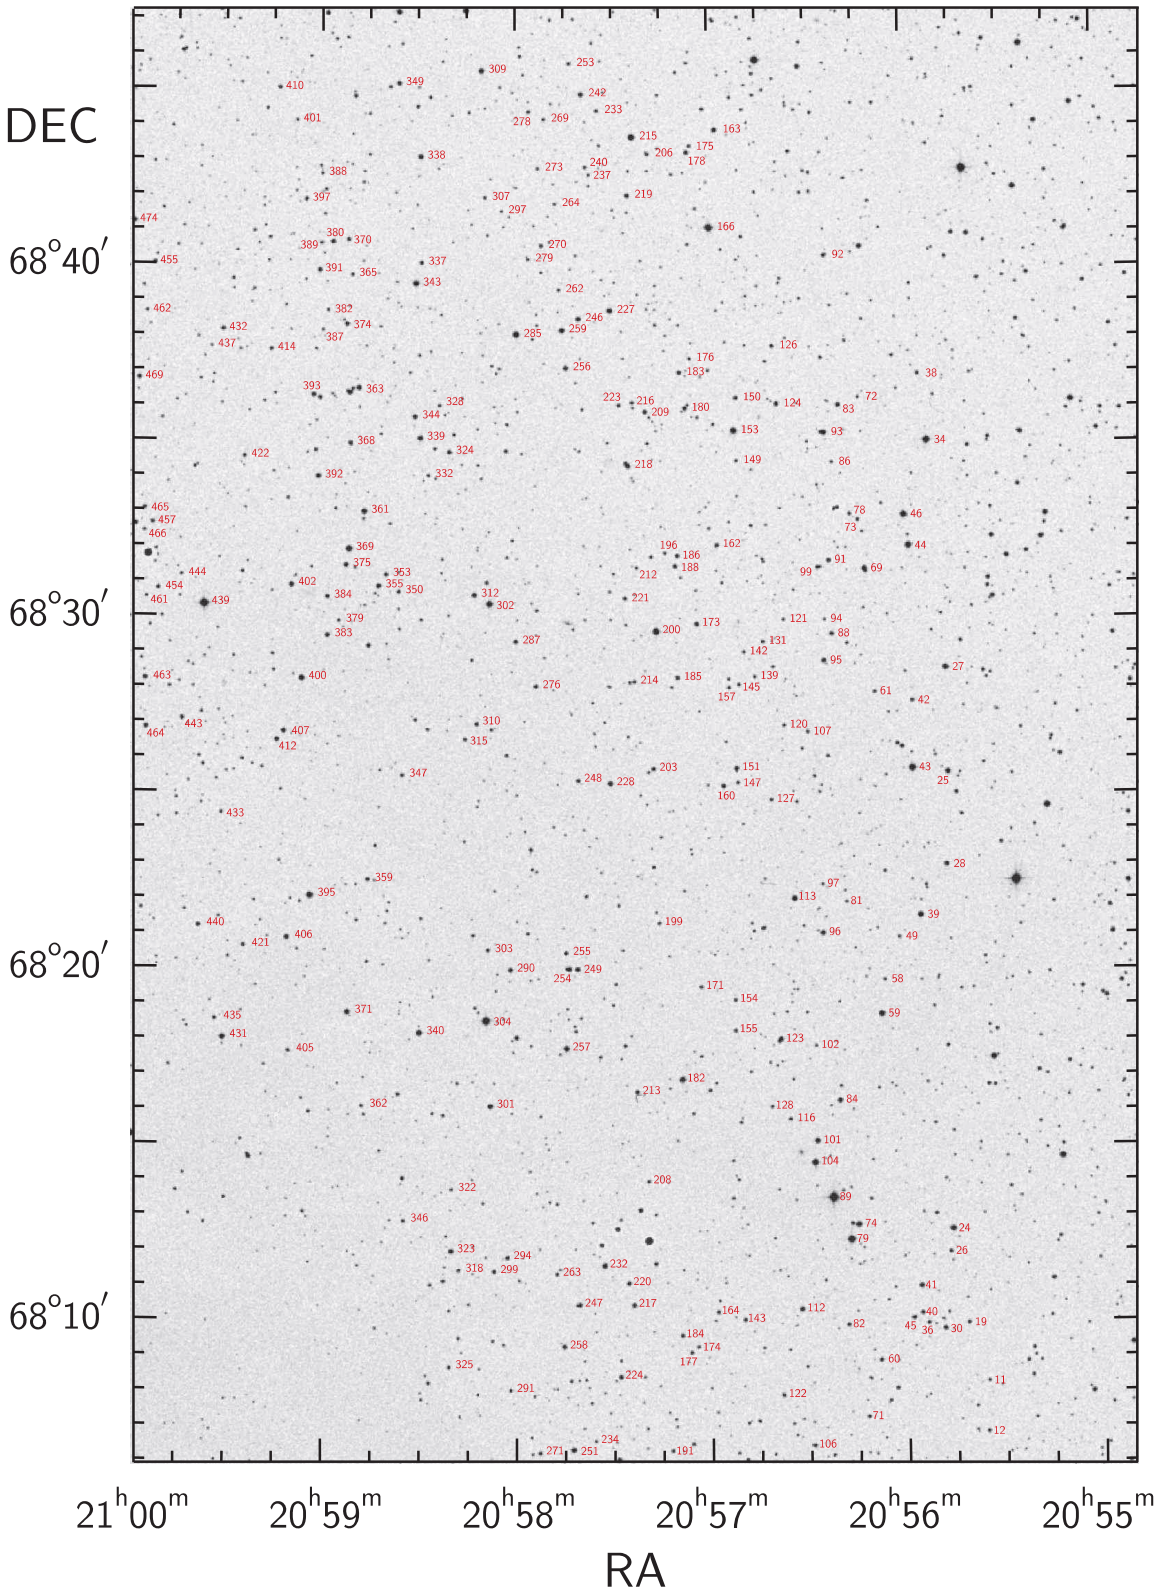

Figure C.2.: Section A of the identification chart in the NGC 7023 area

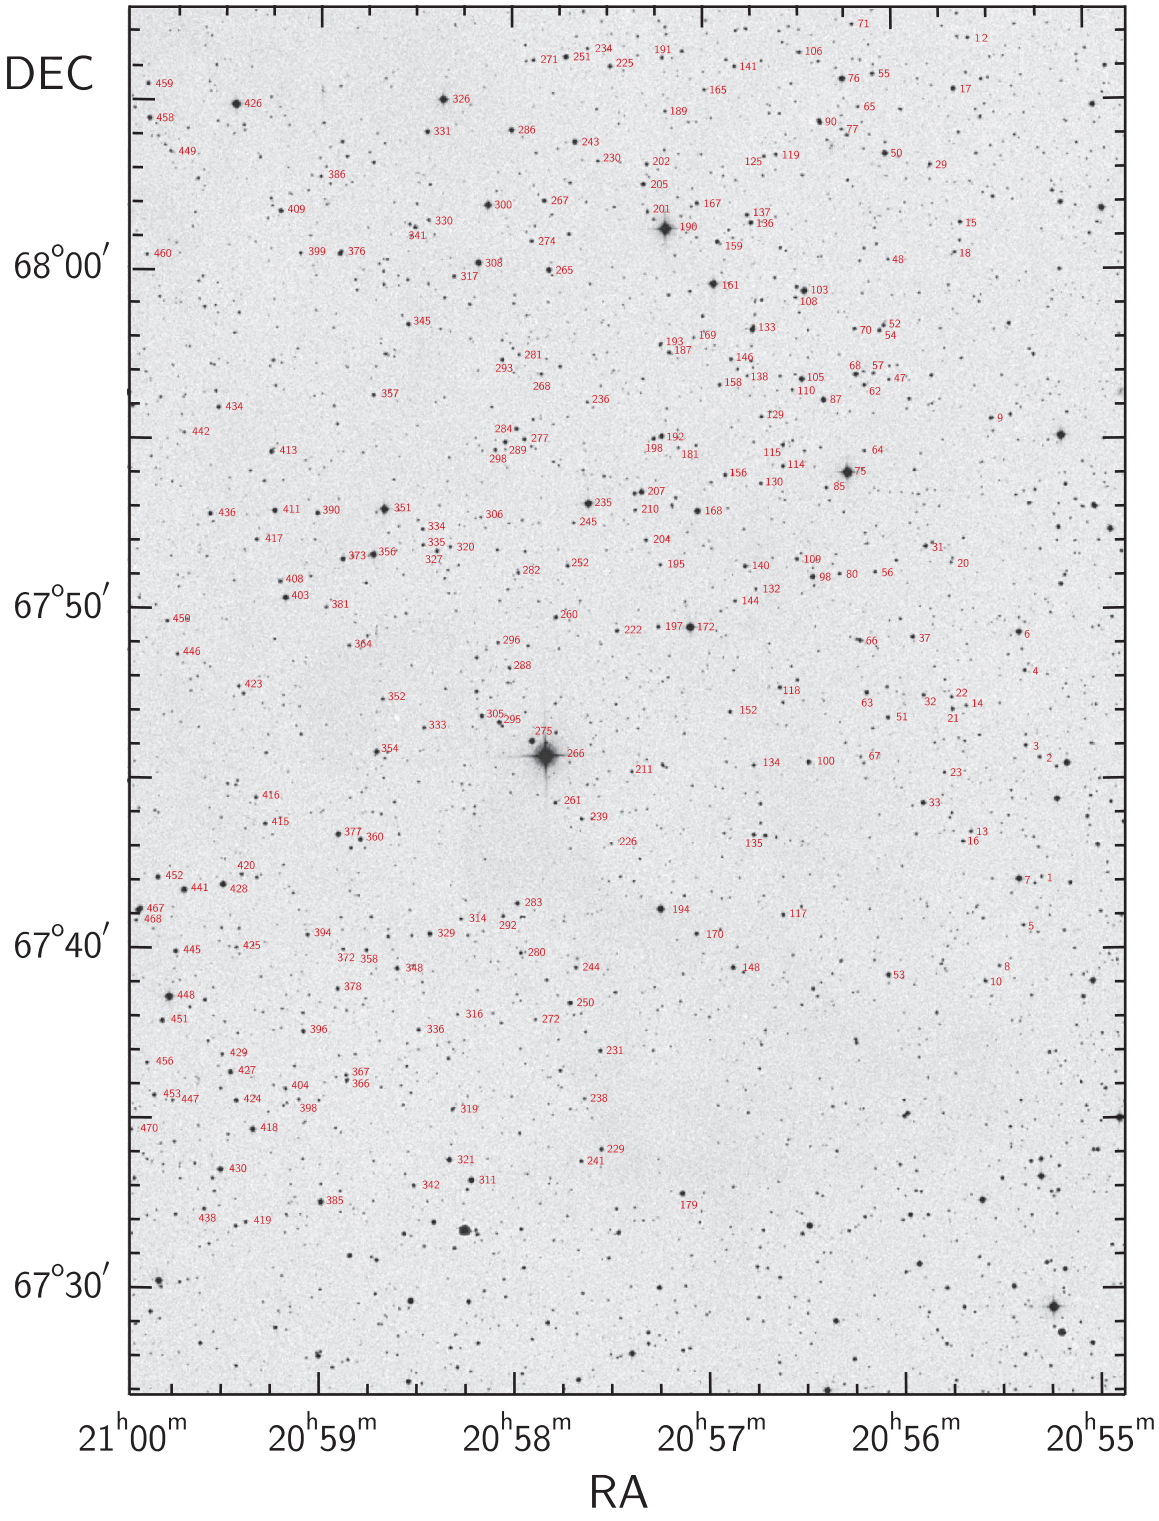

Figure C.3.: Section B of the identification chart in the NGC 7023 area

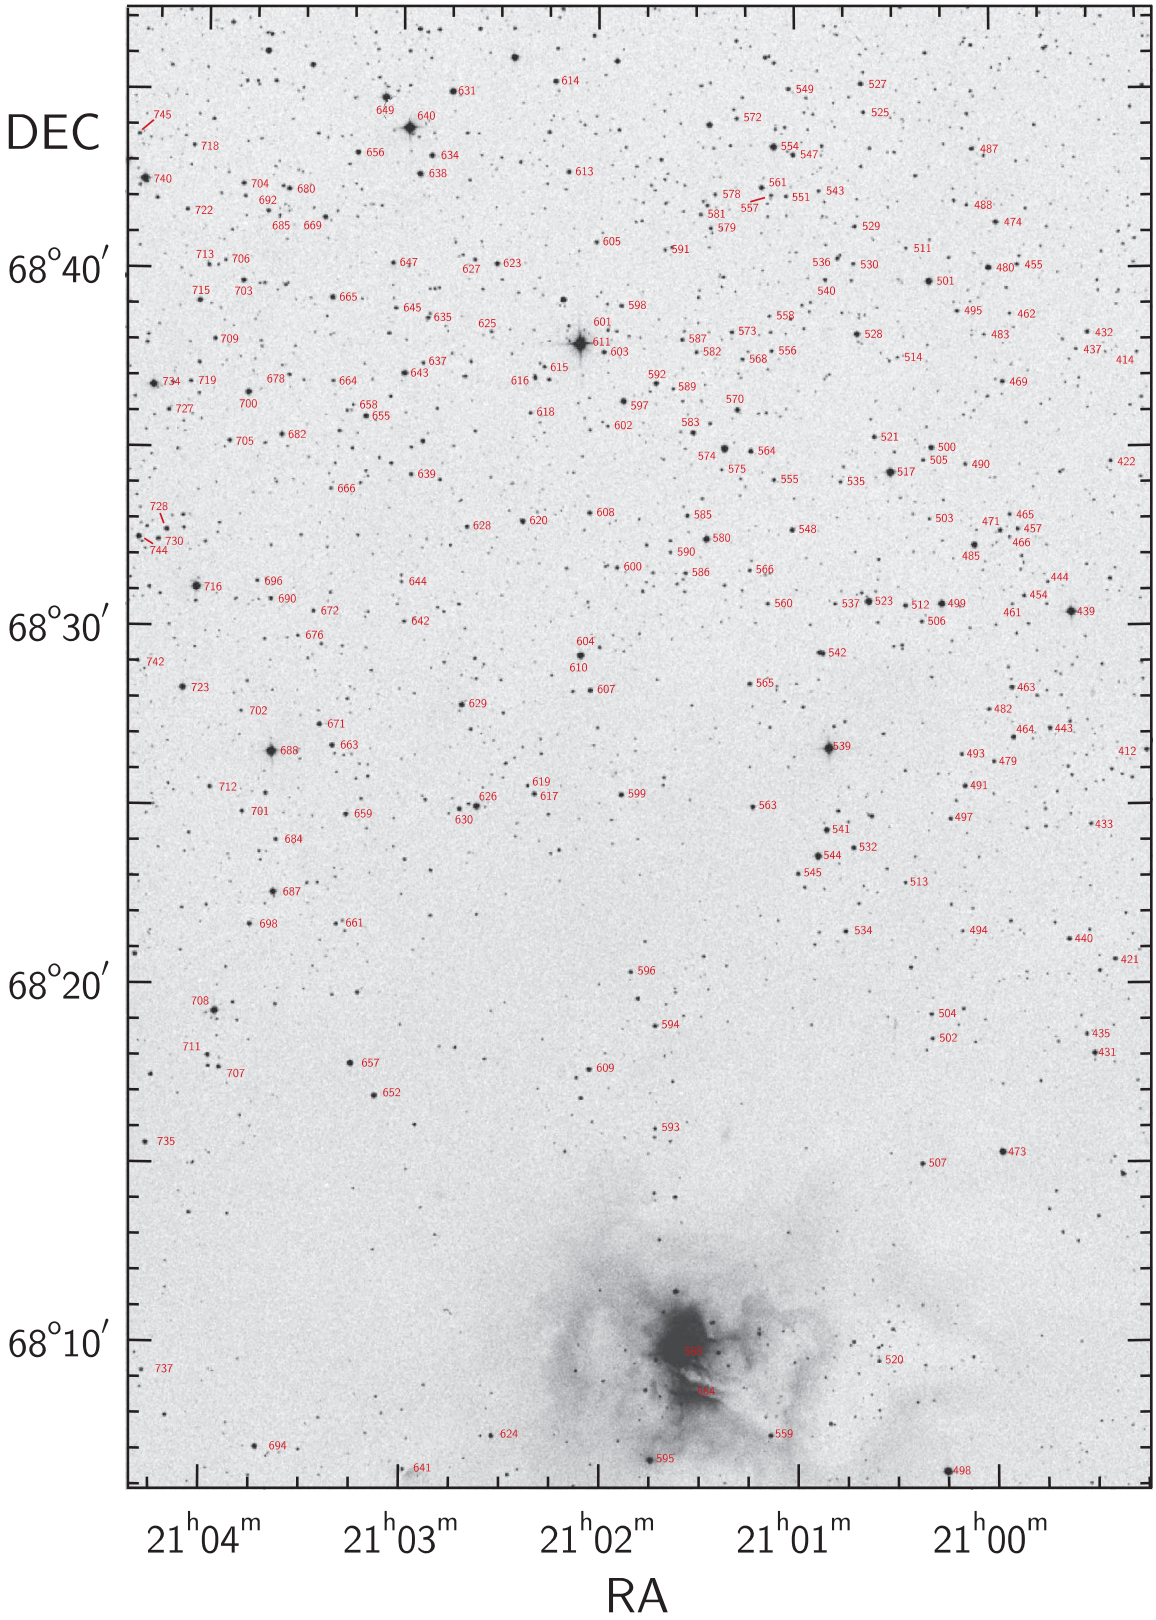

Figure C.4.: Section C of the identification chart in the NGC 7023 area

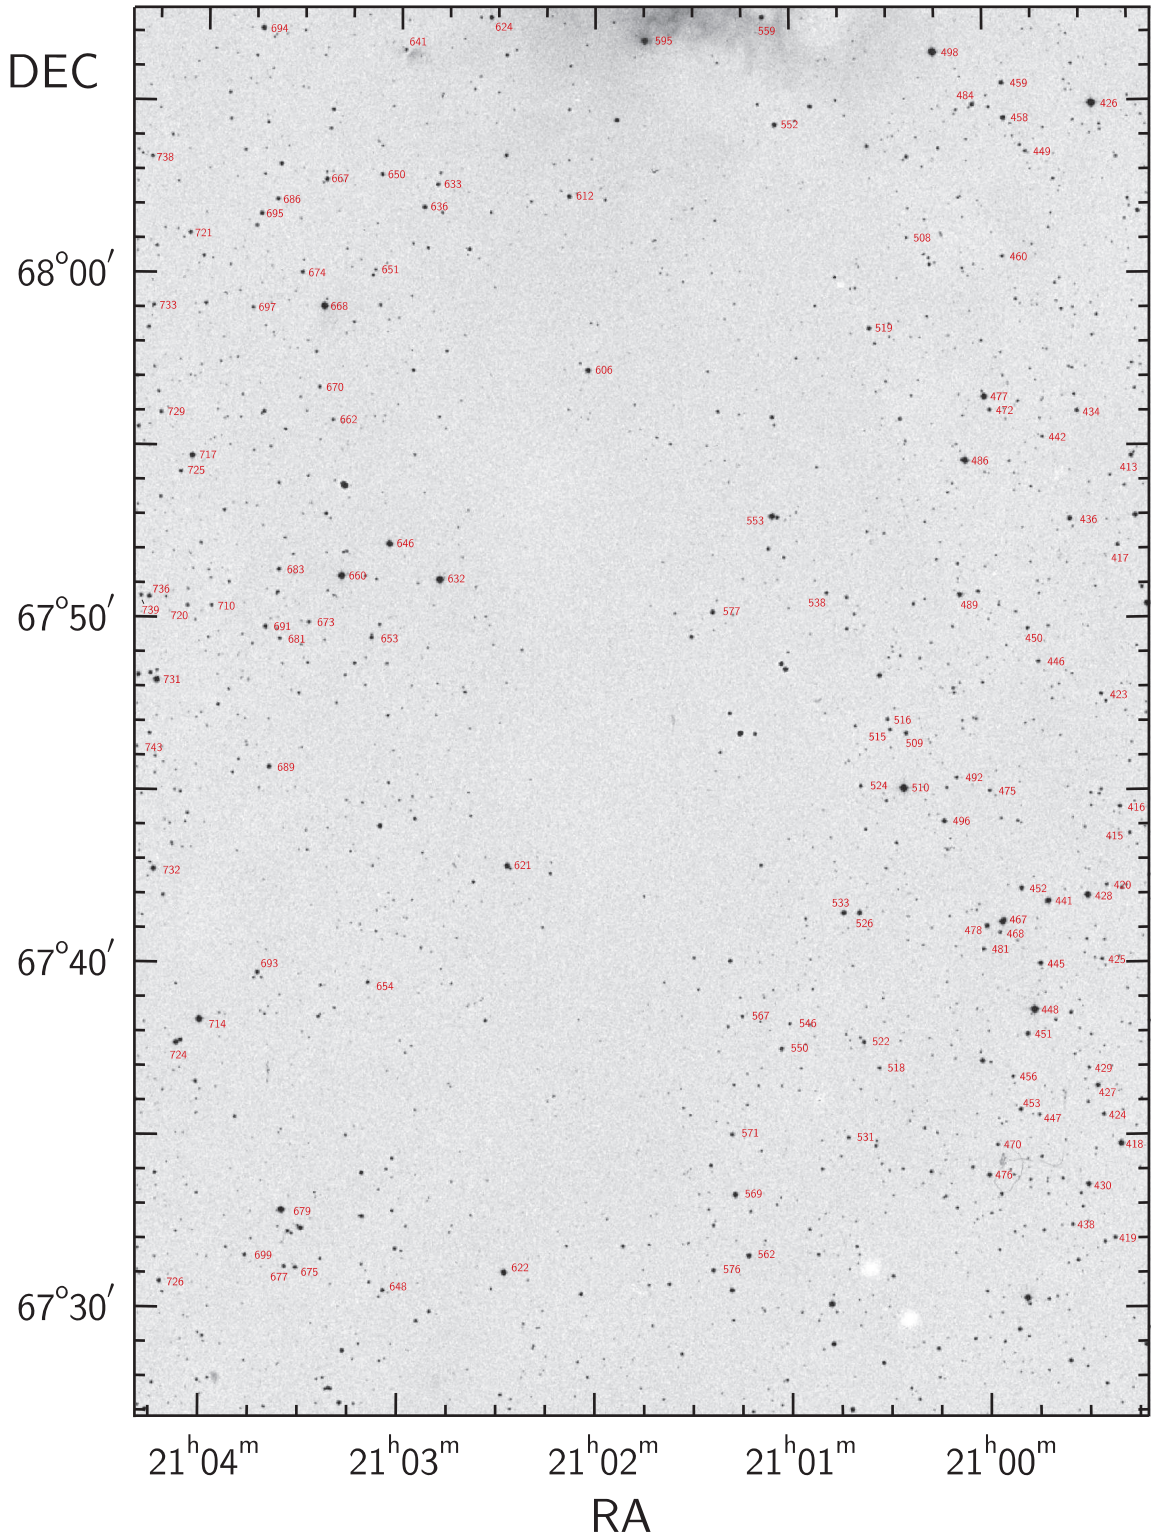

Figure C.5.: Section D of the identification chart in the NGC 7023 area

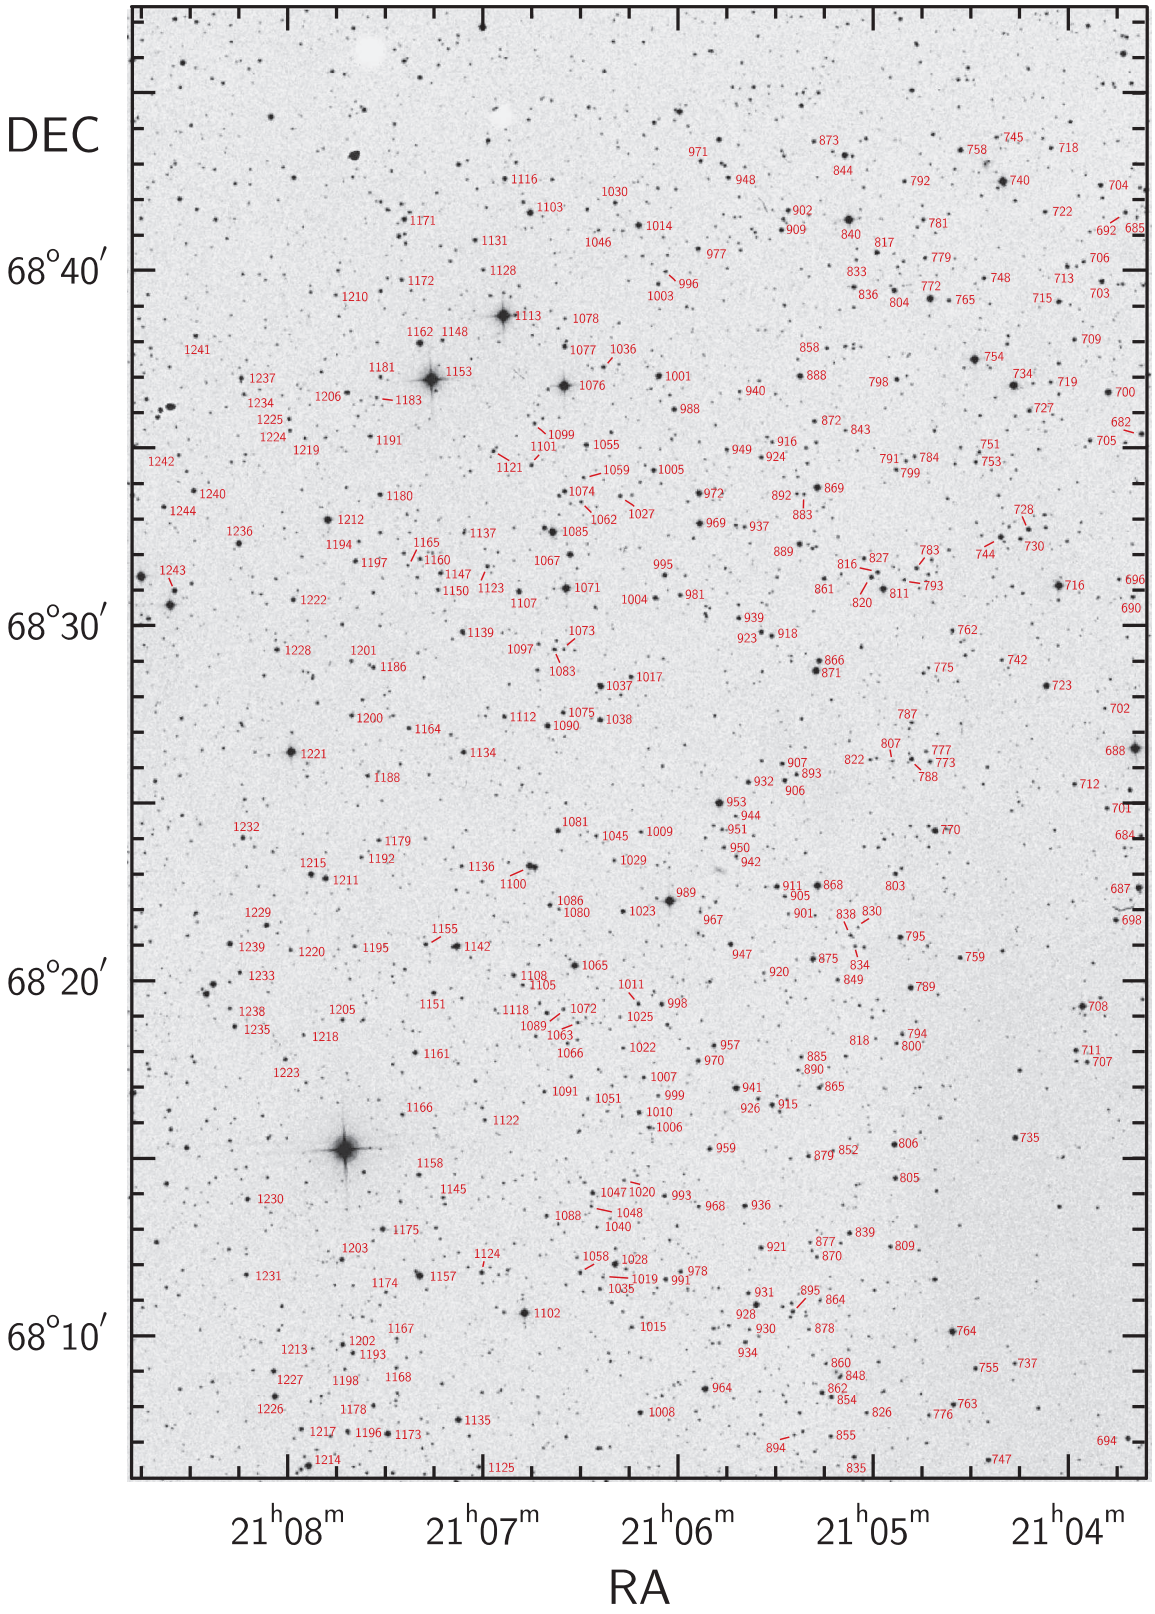

Figure C.6.: Section E of the identification chart in the NGC 7023 area

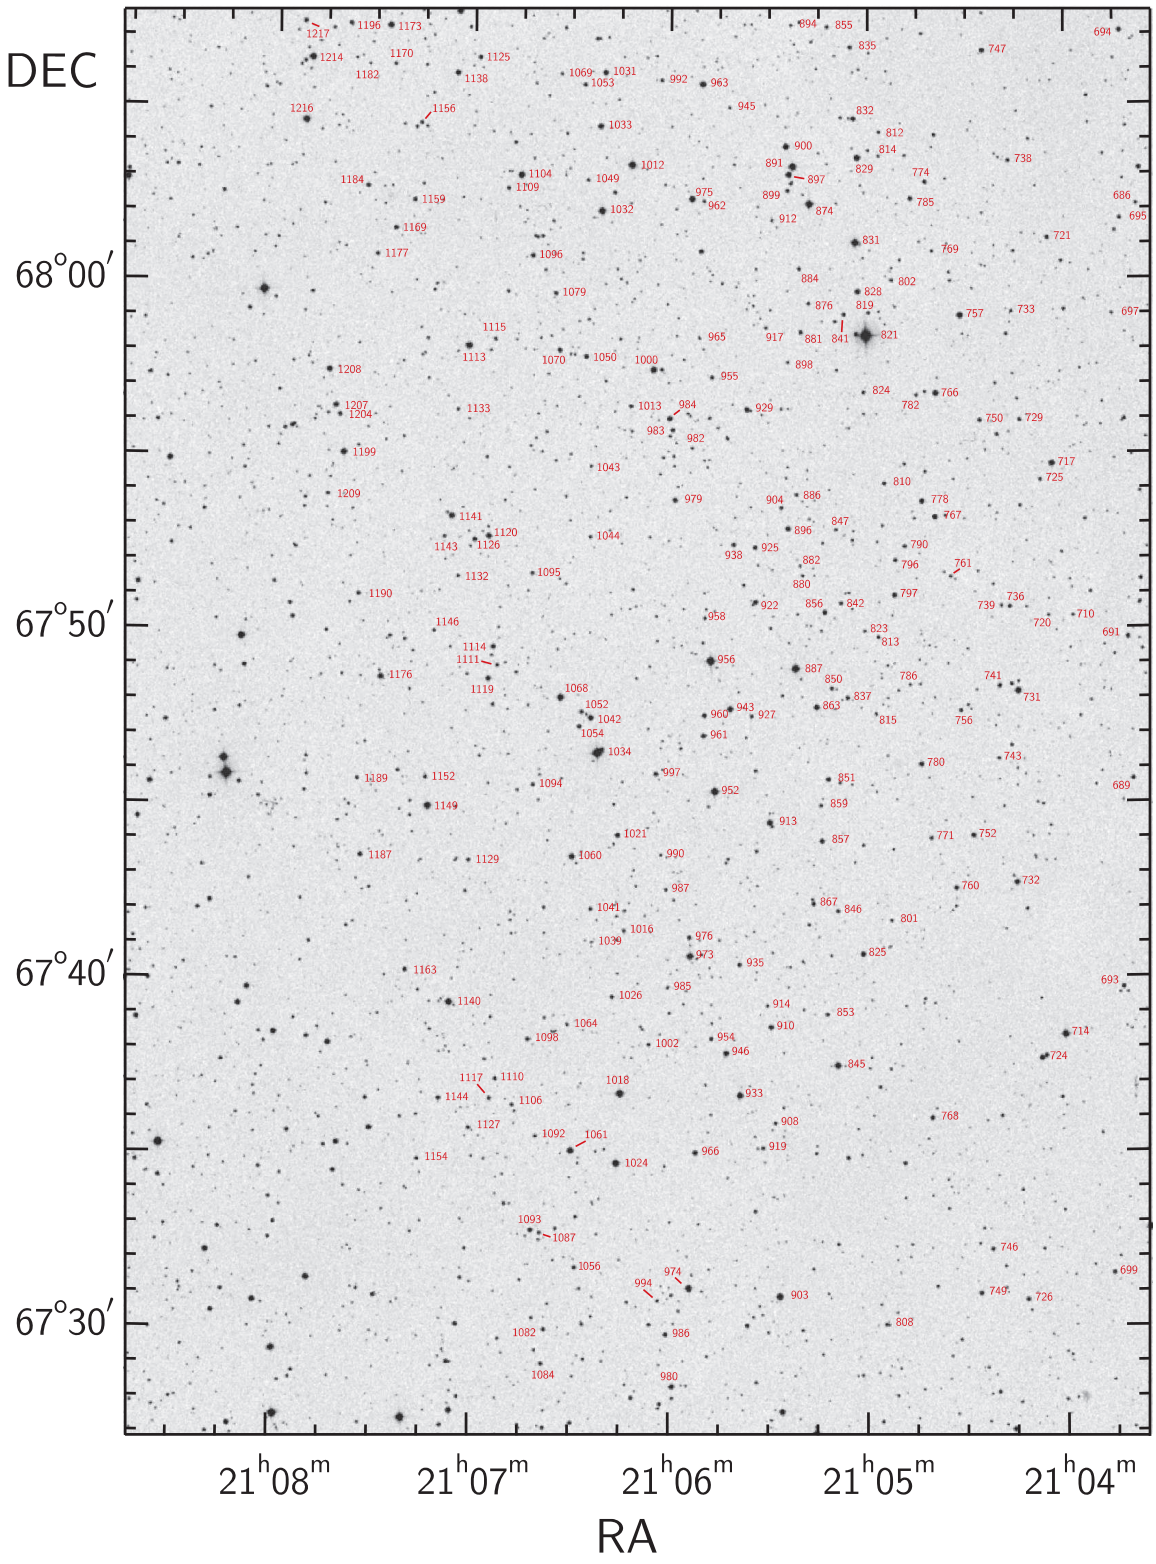

Figure C.7.: Section F of the identification chart in the NGC 7023 area

Finding charts in the TGU 619 area

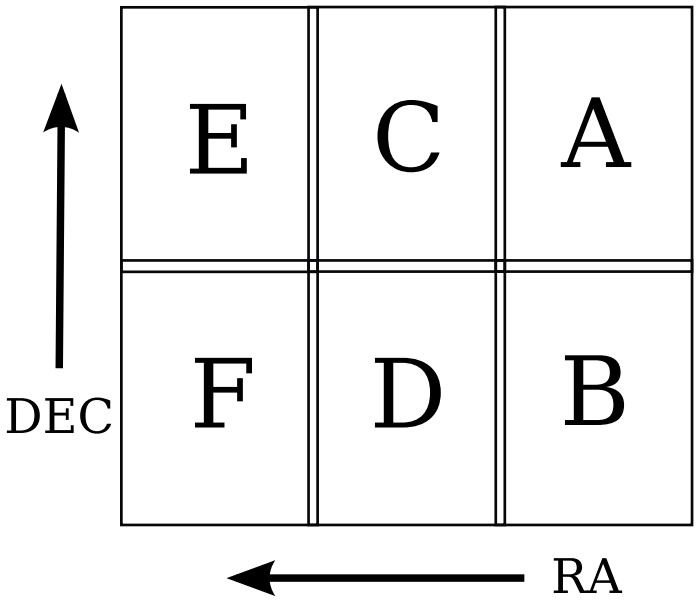

Figure C.8.: Division of the identification chart into six sextions for TGU 619 area shown in Figures C.9-C.14

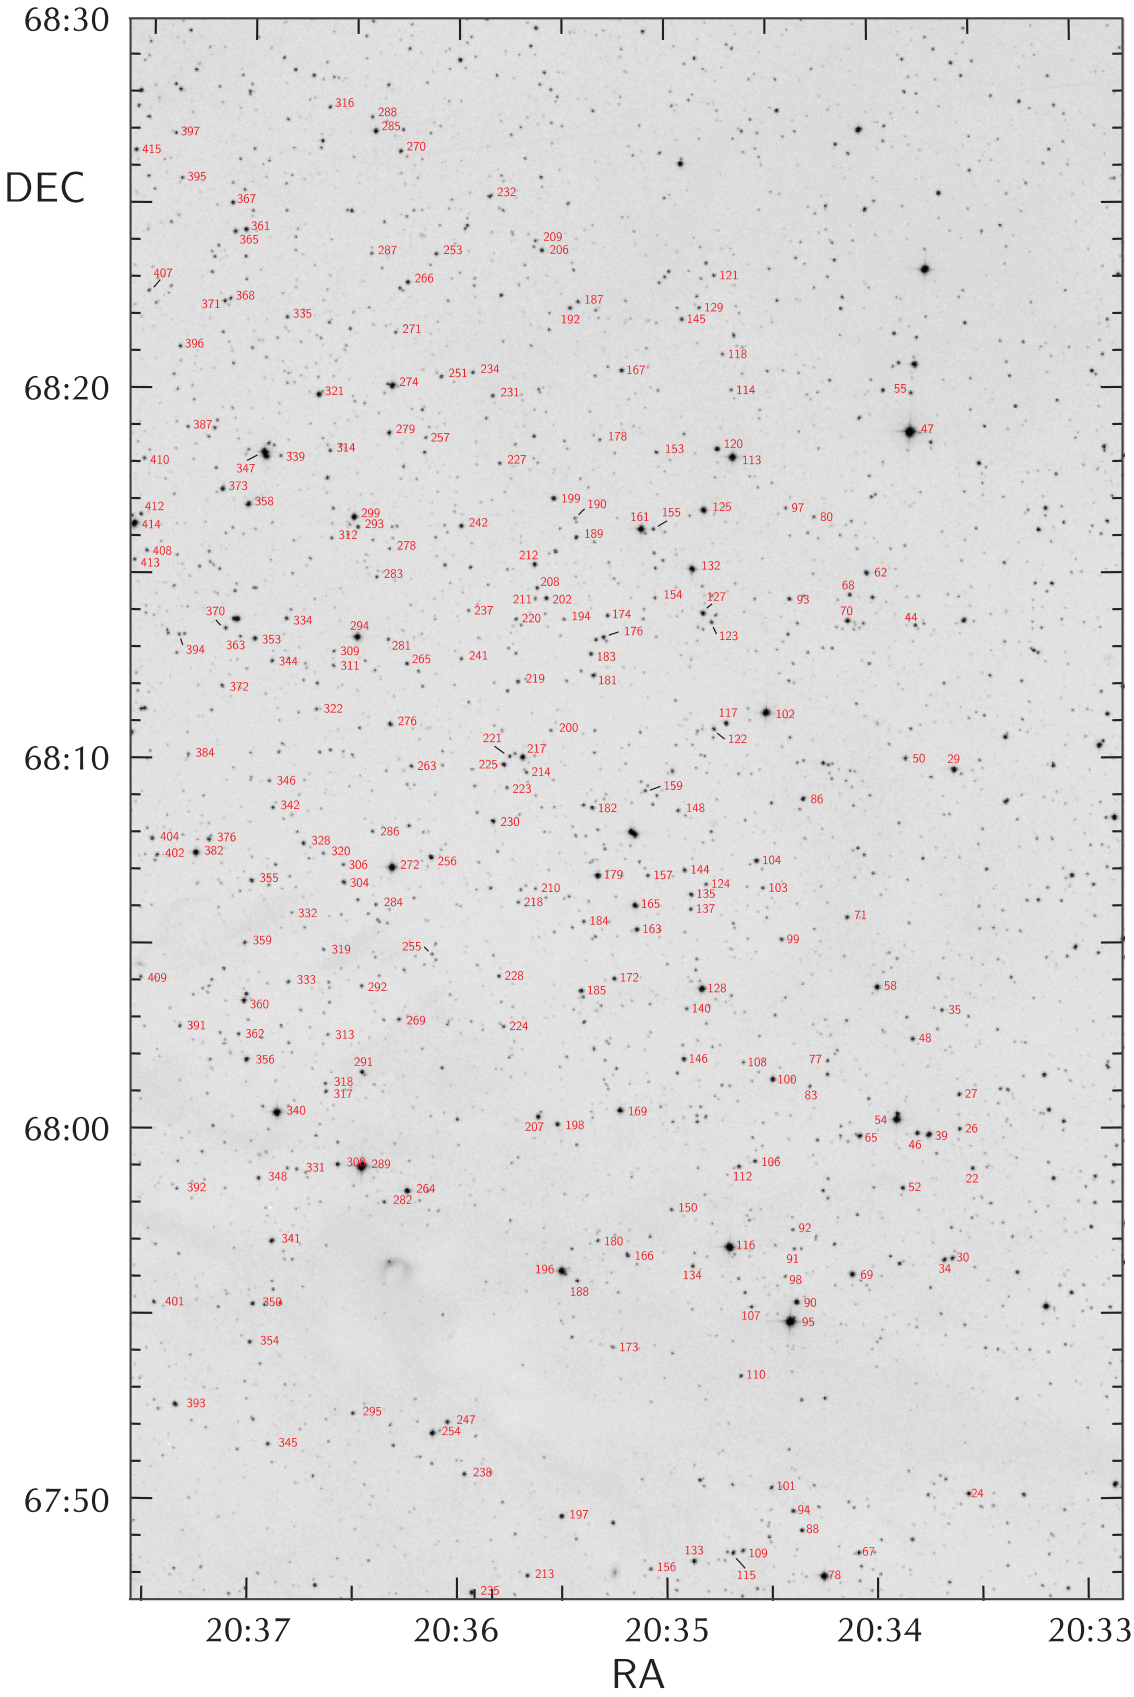

Figure C.9.: Section A of the identification chart in the TGU 619 area

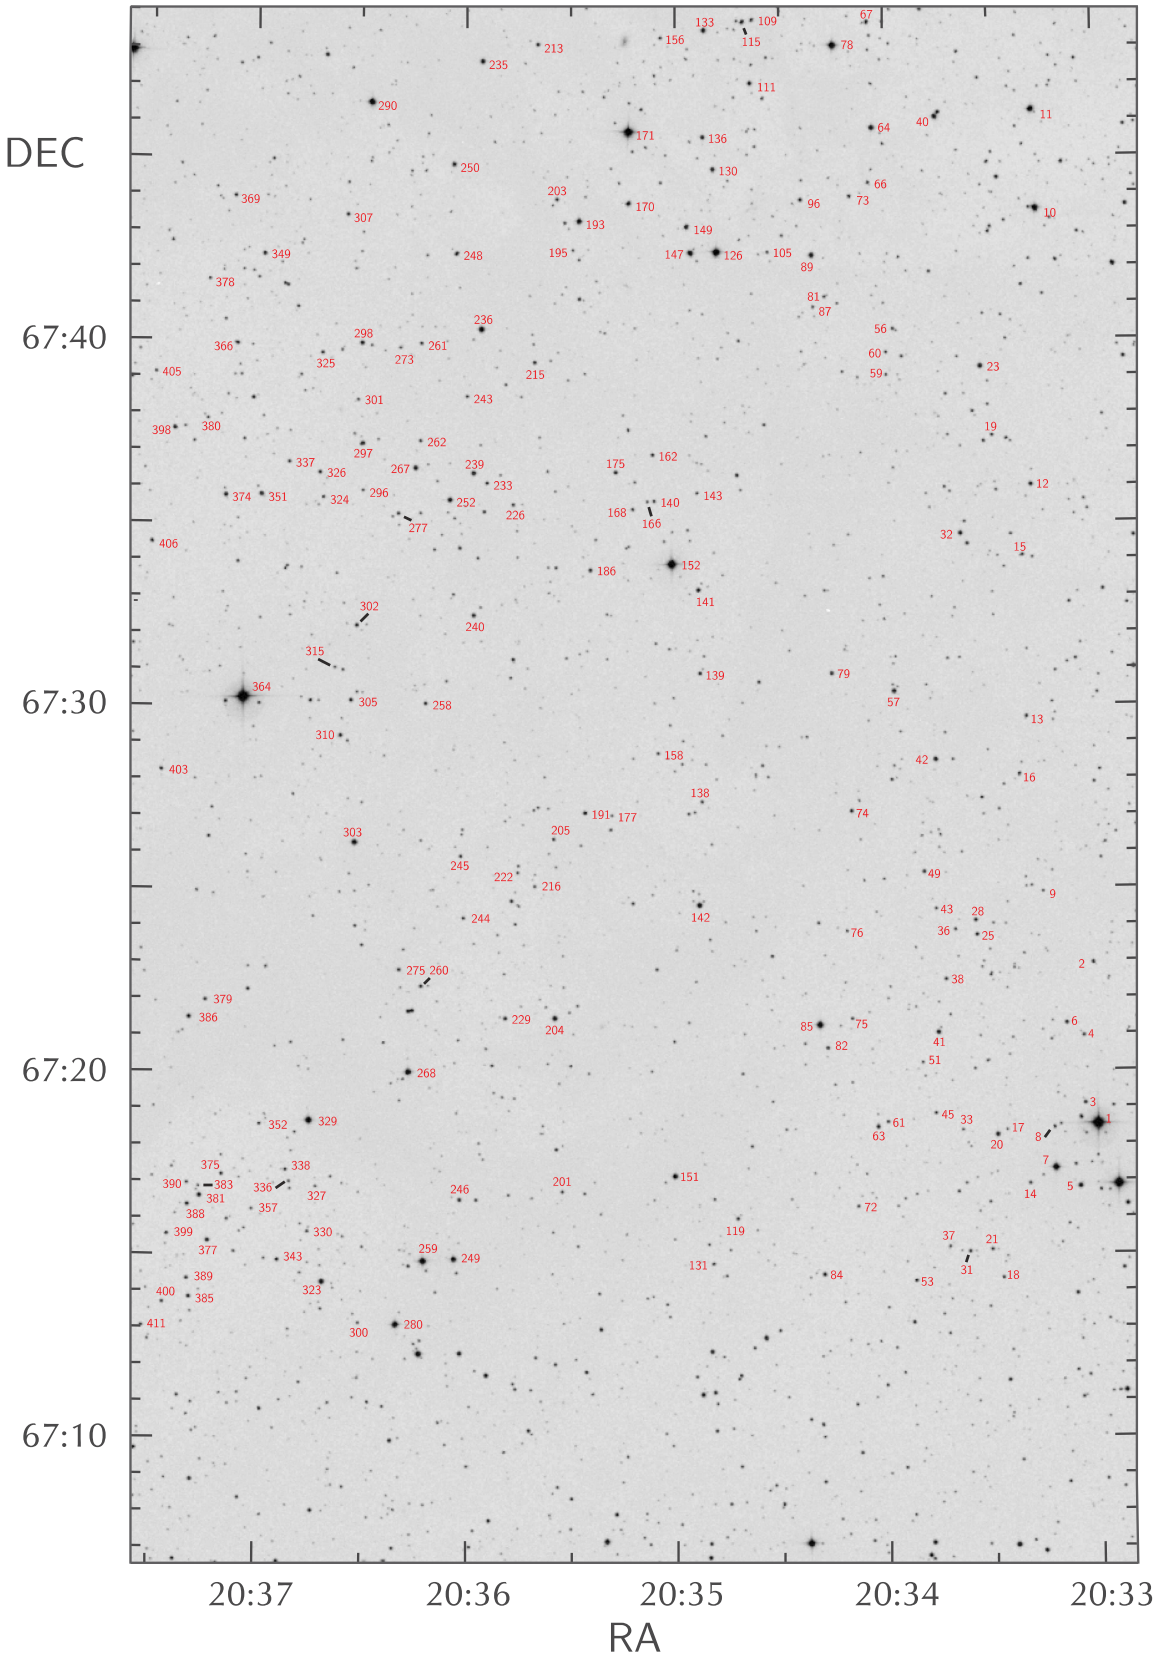

Figure C.10.: Section B of the identification chart in the TGU 619 area

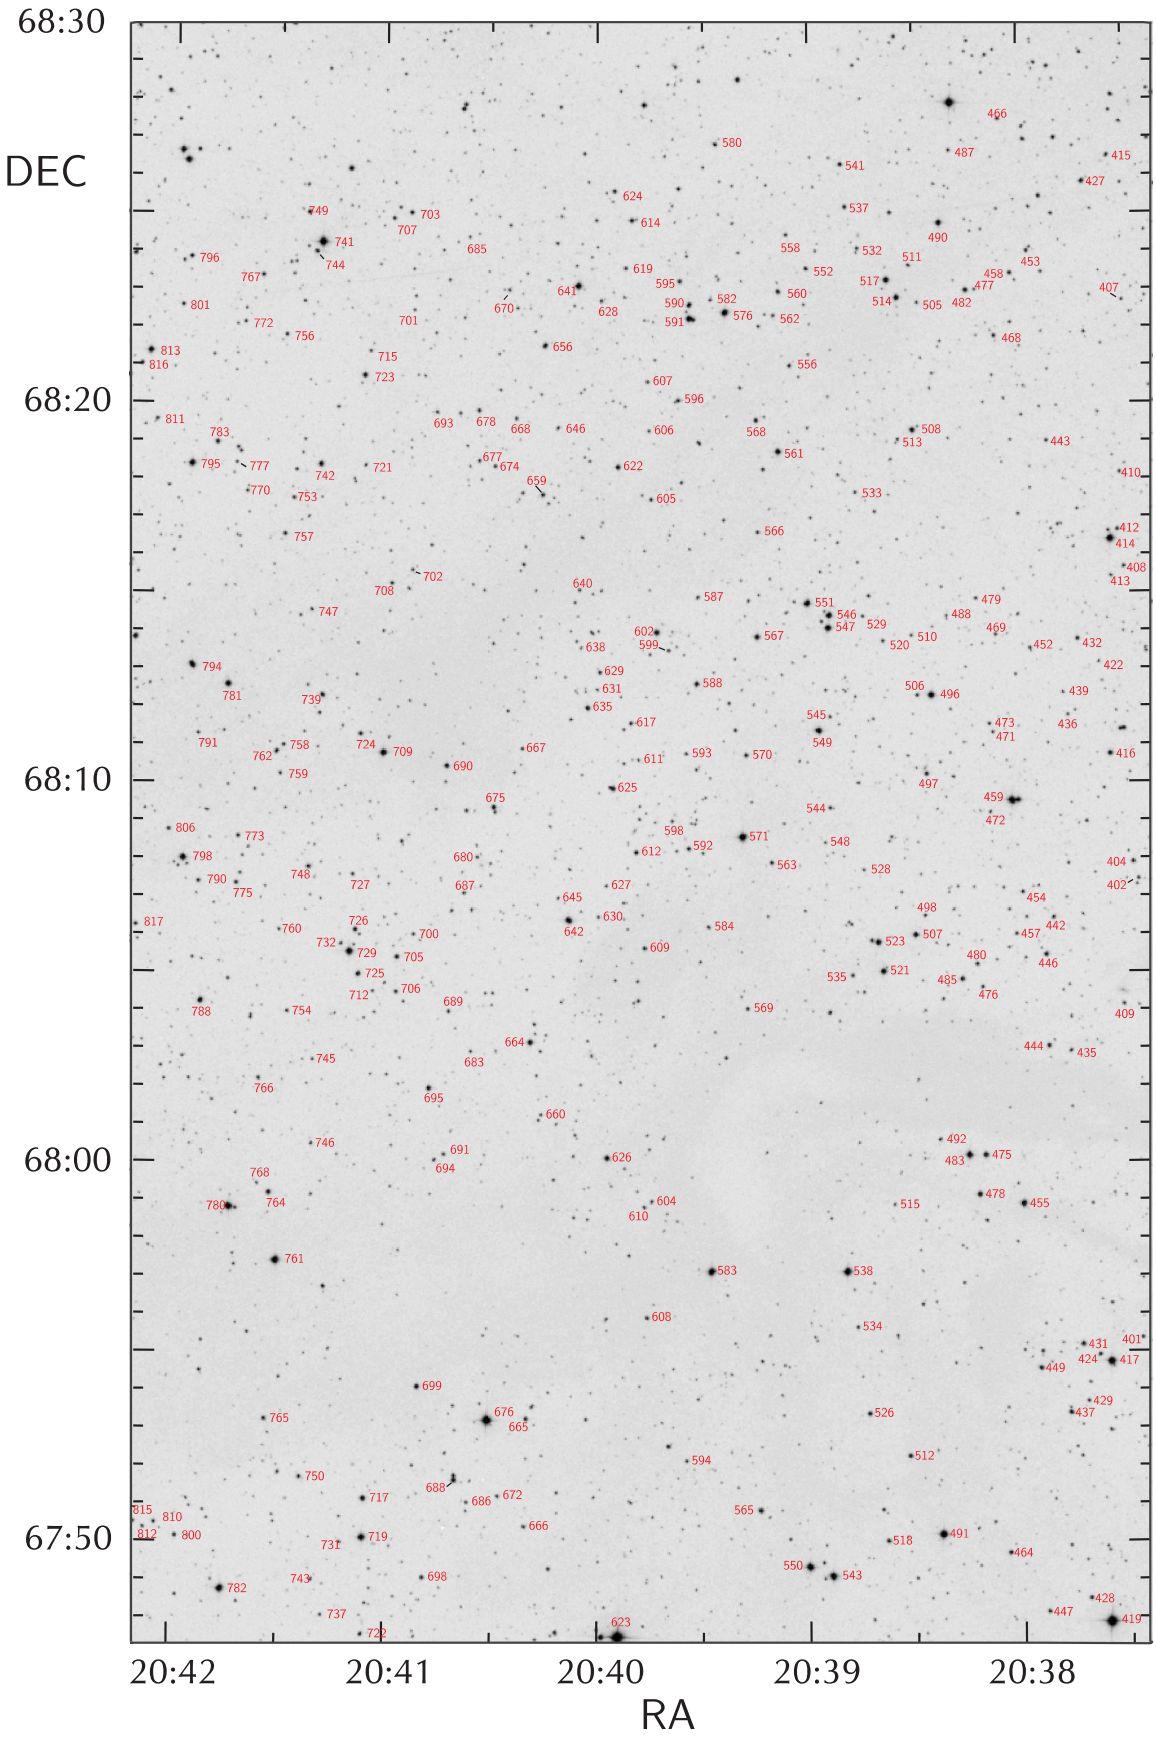

Figure C.11.: Section C of the identification chart in the TGU 619 area

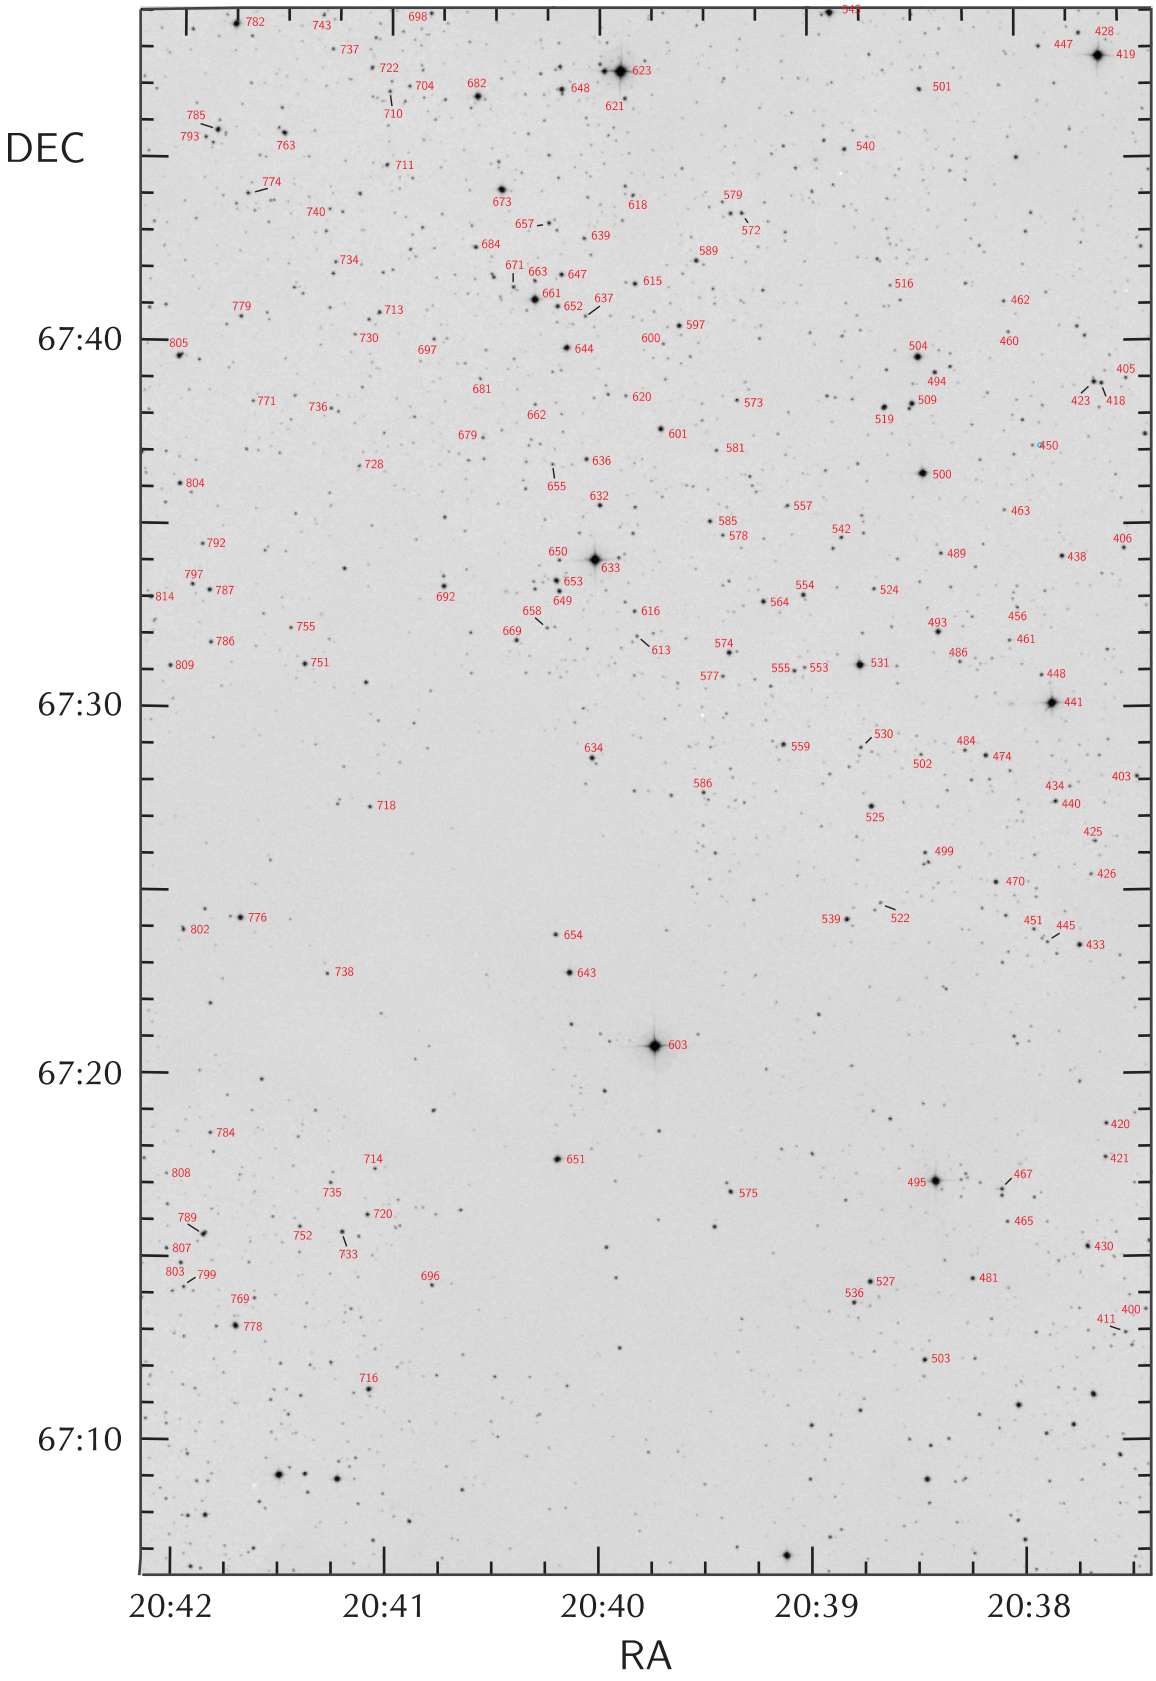

Figure C.12.: Section D of the identification chart in the TGU 619 area

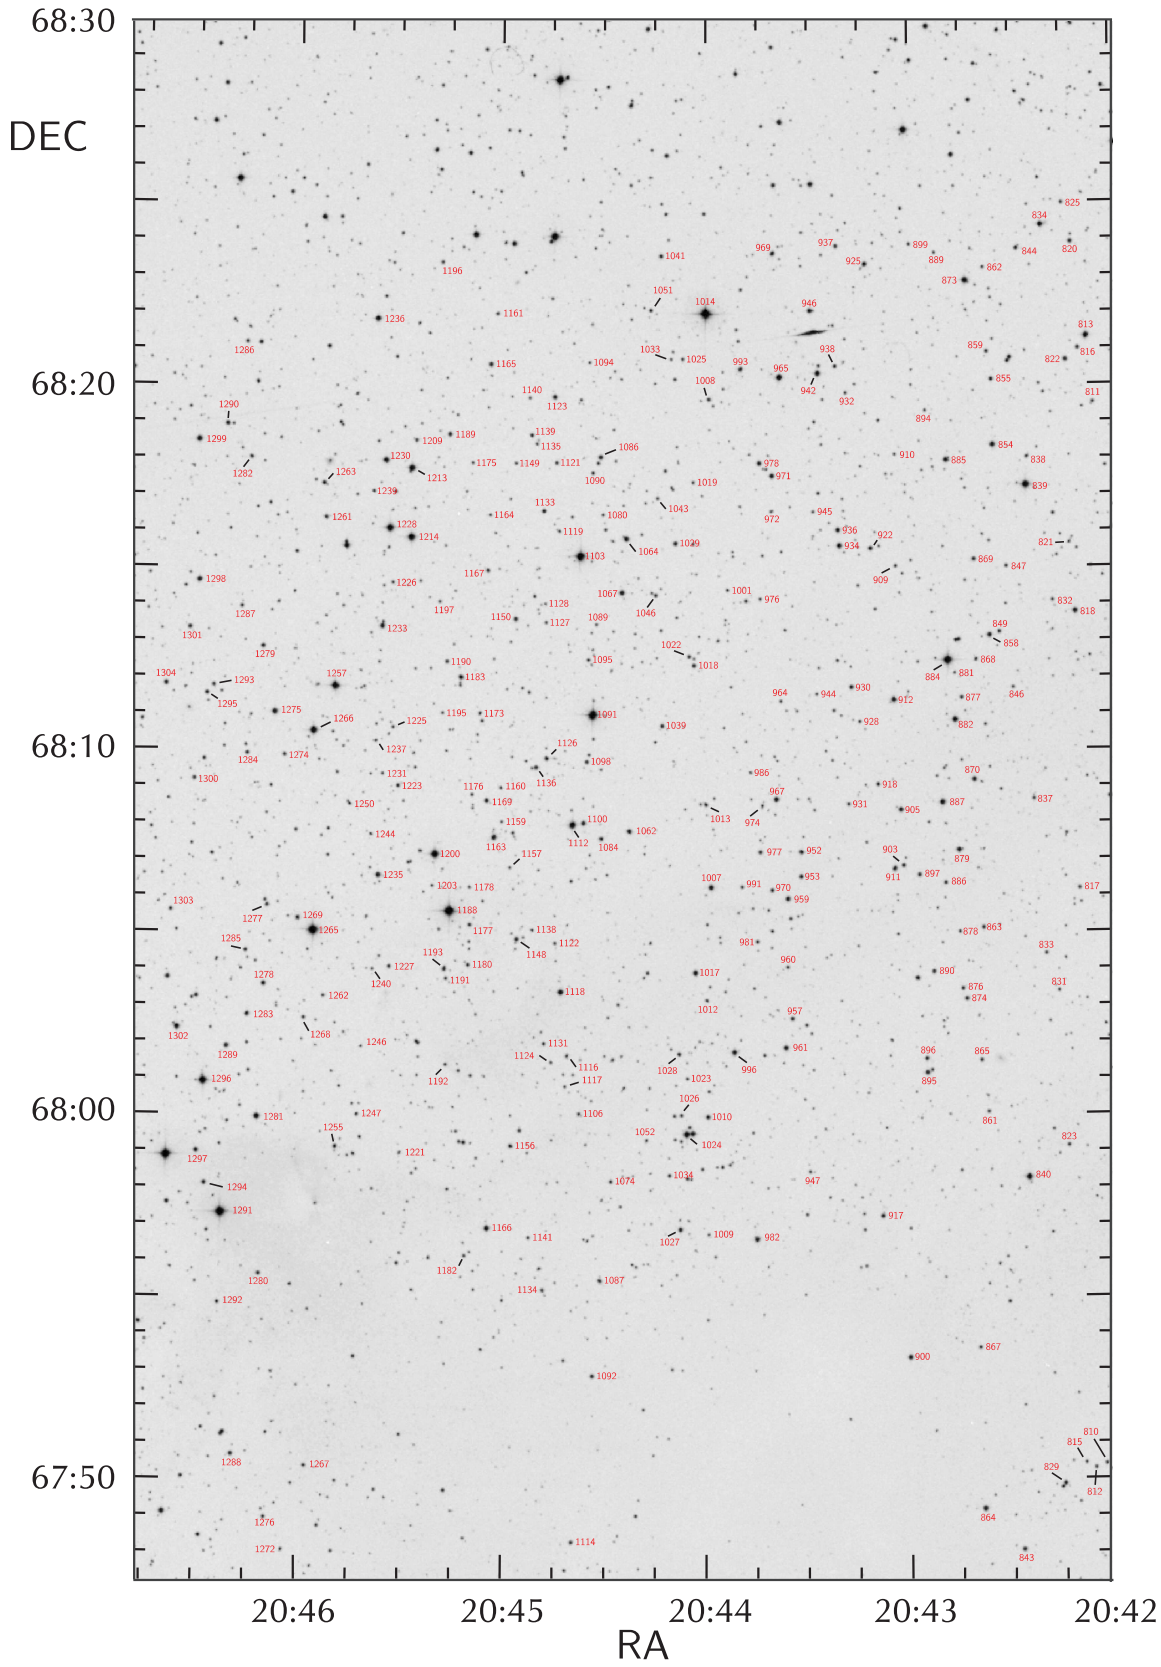

Figure C.13.: Section E of the identification chart in the TGU 619 area

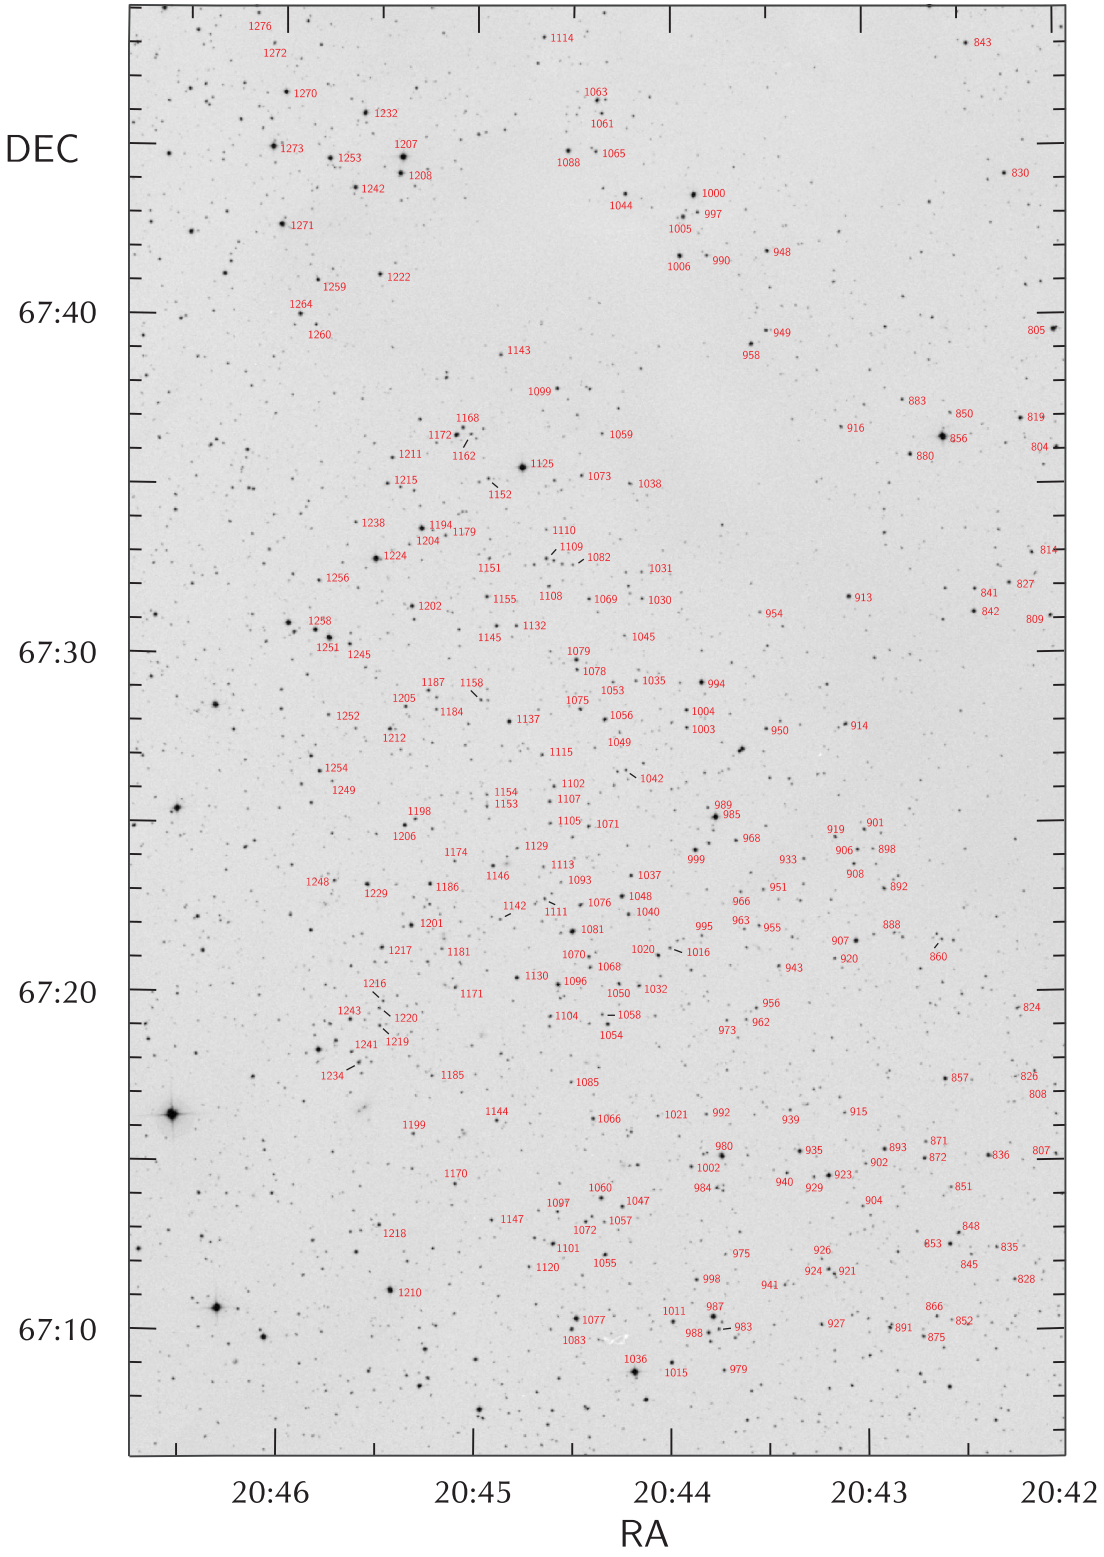

Figure C.14.: Section F of the identification chart in the TGU 619 area

Finding charts in the NGC 7129 and NGC 7142 areas

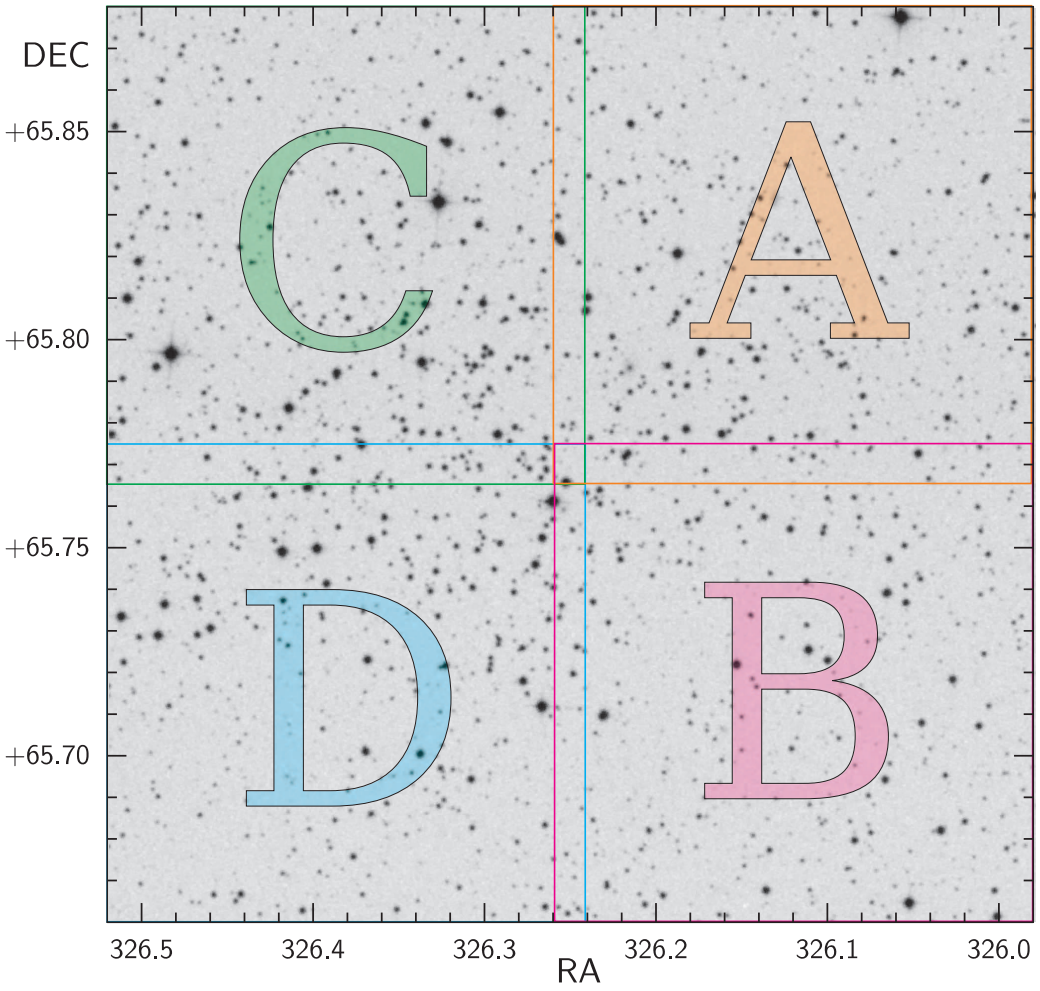

Figure C.15.: Division of the identification chart into four sextions for NGC 7142 area shown in Figures C.16-C.19

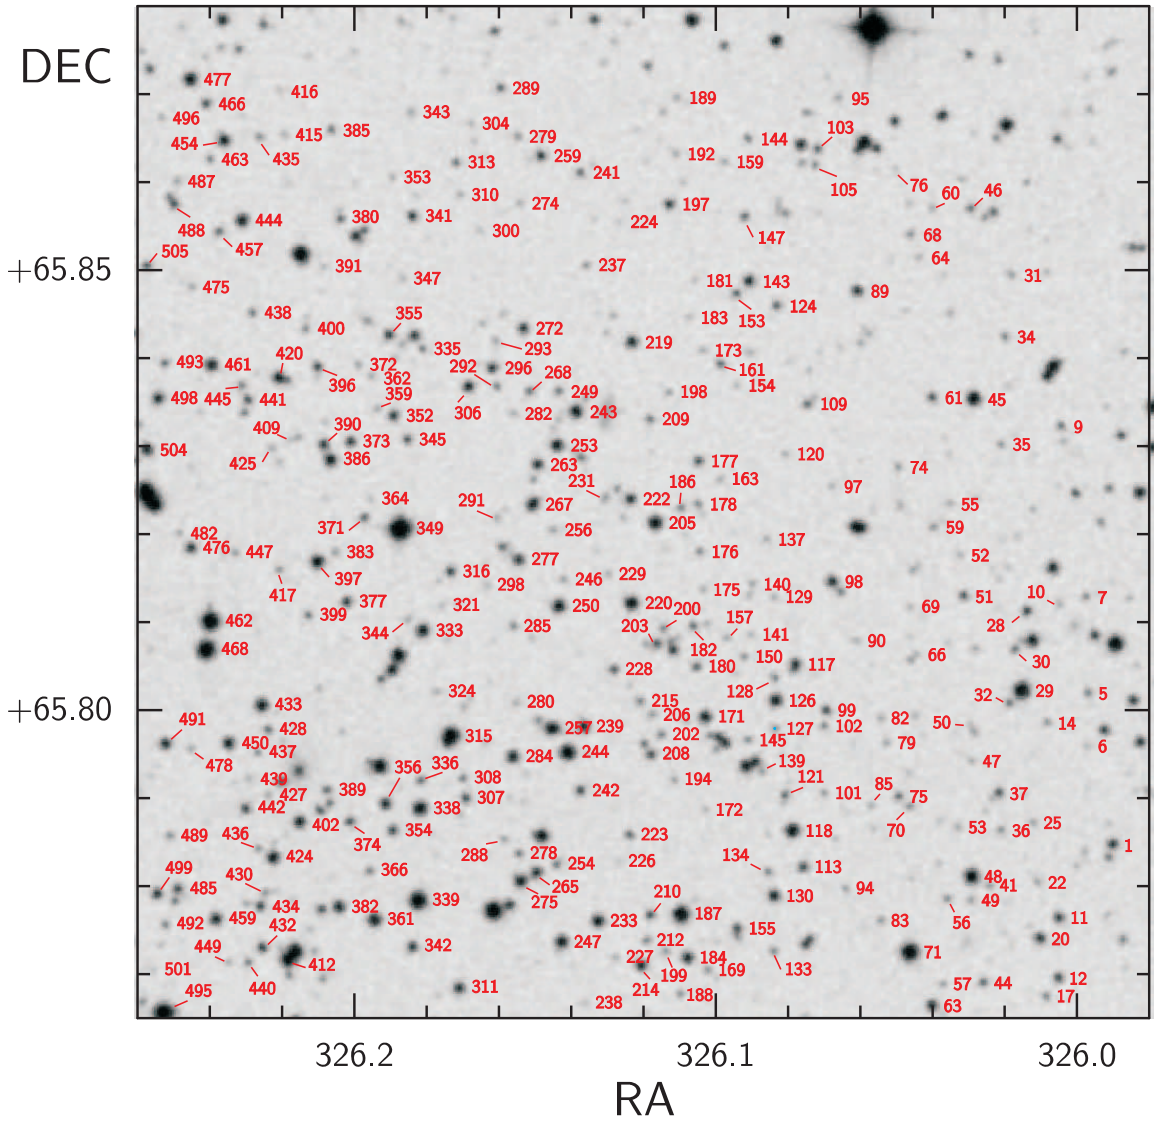

Figure C.16.: Section A of the identification chart in the NGC 7142 area

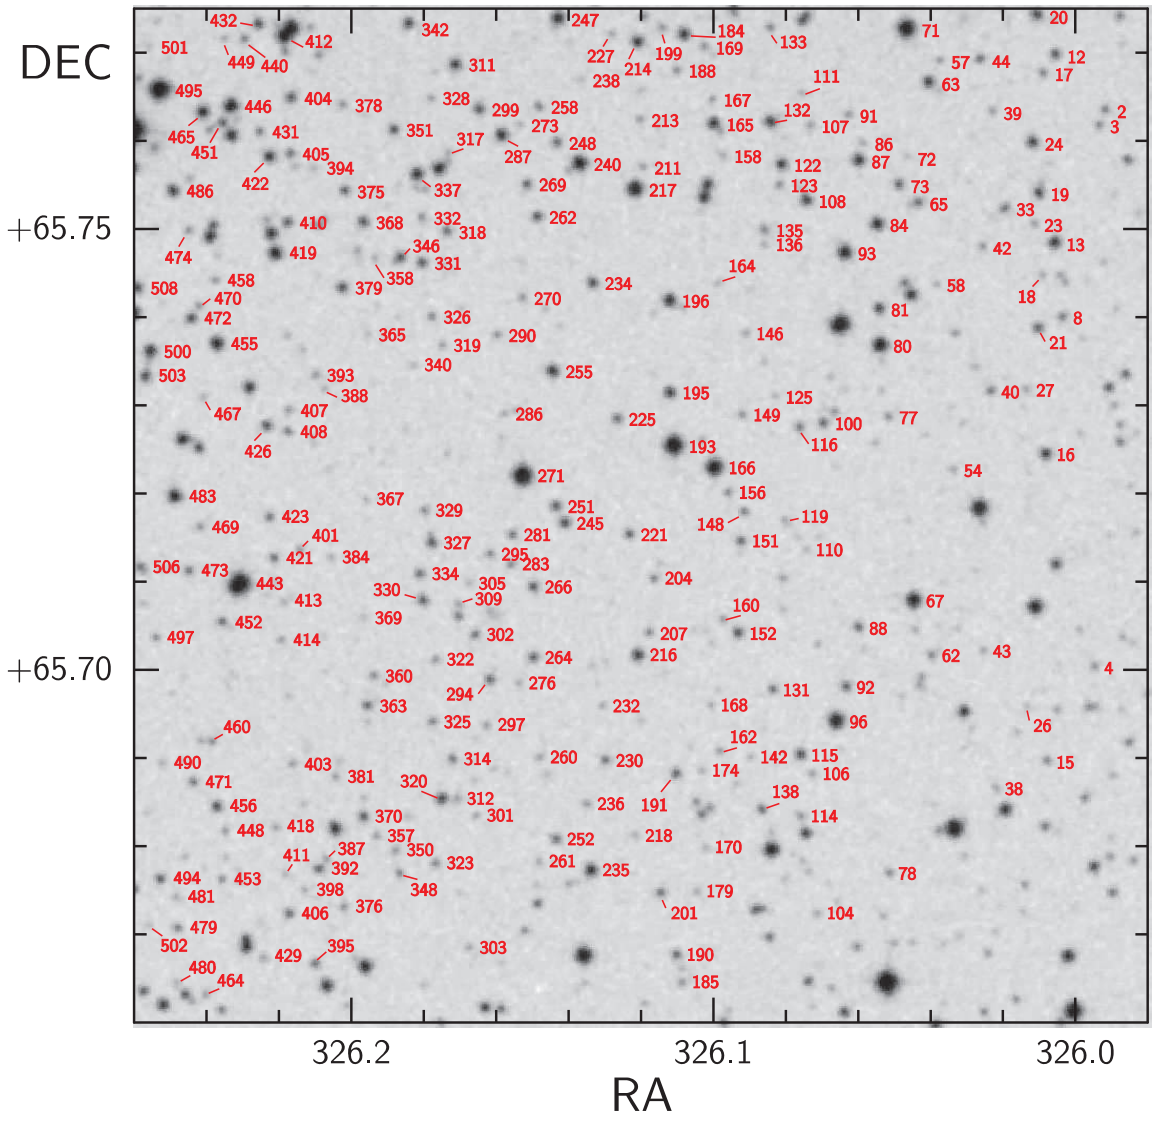

Figure C.17.: Section B of the identification chart in the NGC 7142 area

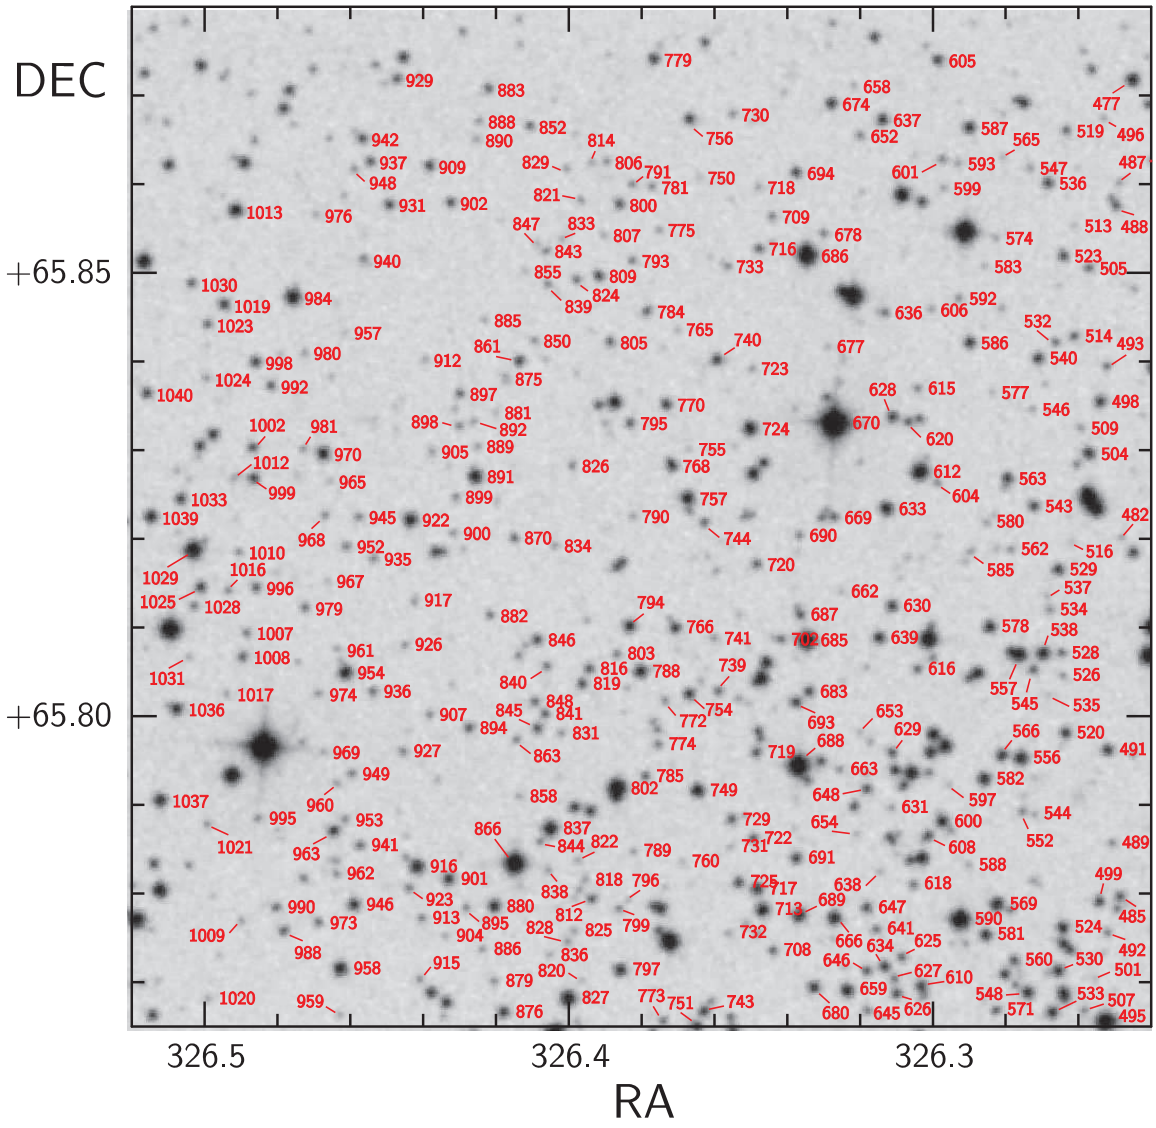

Figure C.18.: Section C of the identification chart in the NGC 7142 area

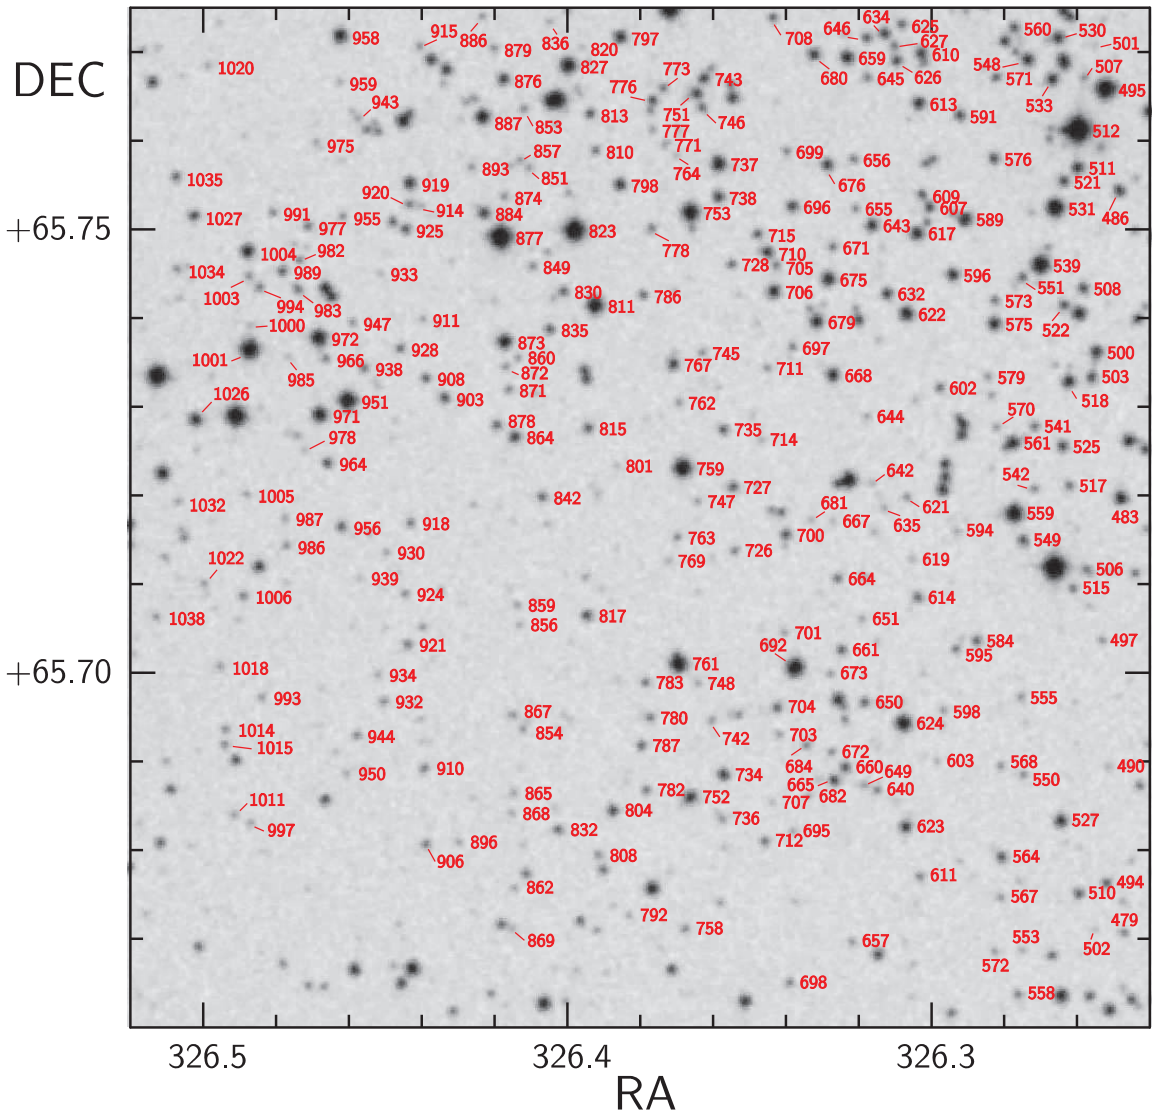

Figure C.19.: Section D of the identification chart in the NGC 7142 area

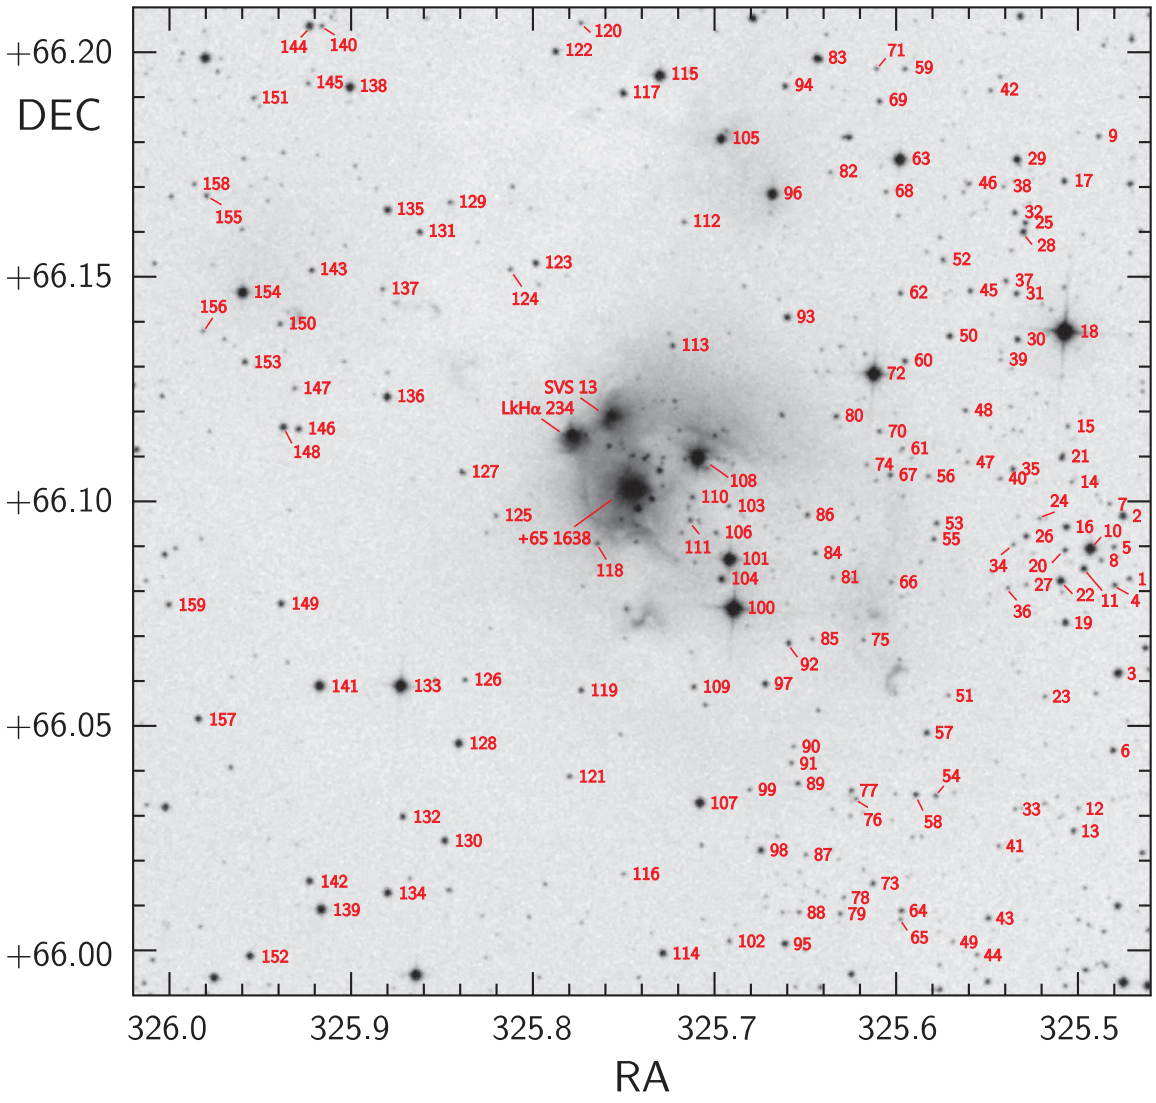

Figure C.20.: Identification chart in the NGC 7129 area
