Abstract. In the paper a joint limit theorem for zeta-functions of newforms on the complex plane is proved.

Keywords: limit theorem, zeta-function, newform.

Let $SL(2, \mathbb{Z})$ be the full modular group, and for $q \in \mathbb{Z}$,

$$\Gamma_0(q) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in S(2\mathbb{Z}) : c \equiv 0 \pmod{q} \right\}$$

be its Hecke subgroup.

Suppose that $F(z)$ is a holomorphic function on the upper half plane $\text{Im } z > 0$, for all $\begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma_0(q)$ satisfies the functional equation

$$F\left(\frac{az + b}{cz + d}\right) = (cz + d)^k F(z), \quad k \in 2\mathbb{N},$$

and is holomorphic and vanishing at cusps. Then $F(z)$ is called a cusp form of weight k and level q , and has the following Fourier series expansion at infinity

$$F(z) = \sum_{m=1}^{\infty} c(m) e^{2\pi i m z}.$$

Denote the space of all cusp forms of weight k and level q by $S_k(\Gamma_0(q))$. For every $d|q$, the element of the space $S_k(\Gamma_0(d))$ can be also considered as an element of the space $S_k(\Gamma_0(q))$. The form $F \in S_k(\Gamma_0(q))$ is called a newform if it is not a cusp form of level less than q , and if it is an eigenfunction of all Hecke operators. Then we have that $c(1) \neq 0$, therefore, we may assume that F is a normalized newform, i.e.,

$$F(z) = \sum_{m=1}^{\infty} c(m) e^{2\pi i m z}, \quad c(1) = 1.$$

Let $s = \sigma + it$ be a complex variable. To a newform F , we attach the L -function $L(s, F)$ defined, for $\sigma > \frac{k+1}{2}$, by

$$L(s, F) = \sum_{m=1}^{\infty} \frac{c(m)}{m^s}.$$

Moreover, $L(s, F)$ has, for $\sigma > \frac{k+1}{2}$, the Euler product over primes

$$L(s, F) = \prod_{p|q} \left(1 - \frac{c(p)}{p^s}\right)^{-1} \prod_{p \nmid q} \left(1 - \frac{c(p)}{p^s} + \frac{1}{p^{2s+1-k}}\right)^{-1},$$

is analytically continuable to an entire function and satisfies the functional equation

$$q^{s/2}(2\pi)^{-s}\Gamma(s)L(s, F) = \varepsilon(-1)^{k/2}q^{(k-s)/2}(2\pi)^{s-k}\Gamma(k-s)L(k-s, F),$$

where $\varepsilon = \pm 1$.

A. Laurinćikas, K. Matsumoto and J. Steuding [1] obtained a limit theorem for the function $L(s, F)$ and applied it for the investigation of the universality of $L(s, F)$. Let $D = \{s \in \mathbb{C} : \frac{k}{2} < \sigma < \frac{k+1}{2}\}$, and $H(D)$ denote the space of analytic functions on D equipped with the topology of uniform convergence on compacta. Let $\mathcal{B}(S)$ stand for the class of Borel sets of the space S . Define

$$\Omega = \prod_p \gamma_p,$$

where $\gamma_p = \{s \in \mathbb{C} : |s| = 1\}$ for all primes p . With the product topology and pointwise multiplication, the torus Ω is a compact topological Abelian group, therefore, on $(\Omega, \mathcal{B}(\Omega))$ the probability Haar measure m_H can be defined. This gives the probability space $(\Omega, \mathcal{B}(\Omega))$. Denote by $\omega(p)$ the projection of $\omega \in \Omega$ to the coordinate space γ_p , and define on the probability space $(\Omega, \mathcal{B}(\Omega), m_H)$ the $H(D)$ -valued random element $L(s, \omega, F)$ by

$$L(s, \omega, F) = \prod_{p|q} \left(1 - \frac{\omega(p)c(p)}{p^s}\right)^{-1} \prod_{p \nmid q} \left(1 - \frac{\omega(p)c(p)}{p^s} + \frac{\omega^2(p)}{p^{2s+1-k}}\right)^{-1}.$$

Let P_L be the distribution of $L(s, \omega, F)$, i.e.,

$$P_L(A) = m_H(\omega \in \Omega : L(s, \omega, F) \in A), \quad A \in \mathcal{B}(H(D)).$$

Denote by $\text{meas}\{A\}$ the Lebesgue measure of a measurable set $A \subset \mathbb{R}$. Then the following statement holds.

Theorem 1. (See [1].) *The probability measure*

$$\frac{1}{T} \text{meas} \{ \tau \in [0, T] : L(s + i\tau, F) \in A \}, \quad A \in \mathcal{B}(H(D)),$$

converges weakly to P_L as $T \rightarrow \infty$.

Our aim is a joint limit theorem for newforms. For $j = 1, \dots, r$, let F_j be a new form of weight k_j and level q_j , and $L(s, F_j)$ be the corresponding L -function given, for $\sigma > \frac{k_j+1}{2}$, by

$$L(s, F_j) = \sum_{m=1}^{\infty} \frac{c_j(m)}{m^s} = \prod_{p|q_j} \left(1 - \frac{c_j(p)}{p^s}\right)^{-1} \prod_{p \nmid q_j} \left(1 - \frac{c_j(p)}{p^s} + \frac{1}{p^{2s+1-k_j}}\right)^{-1},$$

where

$$F_j(z) = \sum_{m=1}^{\infty} c_j(m) e^{2\pi i m z}, \quad c_j(1) = 1.$$

On the probability space $(\Omega, \mathcal{B}(\Omega), m_H)$, define \mathbb{C}^r -valued random element $\underline{L}(\underline{\sigma}, \omega, \underline{F})$ by the formula

$$\underline{L}(\underline{\sigma}, \omega, \underline{F}) = (L(\sigma_1, \omega, F_1), \dots, L(\sigma_r, \omega, F_r)),$$

where

$$L(\sigma_j, \omega, F_j) = \prod_{p|q_j} \left(1 - \frac{\omega(p)c_j(p)}{p^{\sigma_j}}\right)^{-1} \prod_{p \nmid q_j} \left(1 - \frac{\omega(p)c_j(p)}{p^{\sigma_j}} + \frac{\omega^2(p)}{p^{2s+1-k_j}}\right)^{-1},$$

and $\underline{\sigma} = (\sigma_1, \dots, \sigma_r)$, $\underline{F} = (F_1, \dots, F_r)$. Denote by $P_{\underline{L}}$ the distribution of $\underline{L}(\underline{\sigma}, \omega, \underline{F})$. Then we have the following theorem.

Theorem 2. *Suppose that $\sigma_j > \frac{k_j}{2}$, $j = 1, \dots, r$. Then the probability measure*

$$P_T(A) \stackrel{\text{def}}{=} \frac{1}{T} \text{meas} \{t \in [0, T]: (L(\sigma_1 + it, F_1), \dots, L(\sigma_r + it, F_r)) \in A\},$$

$$A \in \mathcal{B}(\mathbb{C}^r),$$

converges weakly to $P_{\underline{L}}$ as $T \rightarrow \infty$.

A generalization of Theorem 2 to the space of analytic functions is also possible.

We will give only a sketch of the proof of Theorem 2. Let \mathbb{P} denote the set of all prime numbers.

Lemma 1. *The probability measure*

$$Q_T(A) \stackrel{\text{def}}{=} \frac{1}{T} \text{meas} \{t \in [0, T]: (p^{-it}: p \in \mathbb{P}) \in A\}, \quad A \in \mathcal{B}(\Omega),$$

converges weakly to the Haar measure m_H on $(\Omega, \mathcal{B}(\Omega))$ as $T \rightarrow \infty$.

Proof of the lemma is given in [1].

Now let $\sigma_1 > \frac{1}{2}$ be fixed, and, for $m, n \in \mathbb{N}$,

$$v_n(m) = \exp \left\{ - \left(\frac{m}{n} \right)^{\sigma_1} \right\}.$$

For $j = 1, \dots, r$ define

$$L_n(s, F_j) = \sum_{m=1}^{\infty} \frac{c_j(m)v_n(m)}{m^s},$$

and, for $\widehat{\omega} \in \Omega$,

$$L_n(s, \widehat{\omega}, F_j) = \sum_{m=1}^{\infty} \frac{c_j(m)\widehat{\omega}(m)v_n(m)}{m^s}.$$

Then the series for $L_n(s, F_j)$ and $L_n(s, \omega, F_j)$ converge absolutely for $\sigma > \frac{k_j}{2}$.

Lemma 2. *Suppose that $\sigma_j > \frac{k_j}{2}$, $j = 1, \dots, r$. Then the probability measures*

$$P_{T,n}(A) \stackrel{\text{def}}{=} \frac{1}{T} \text{meas} \{t \in [0, T]: (L_n(\sigma_1 + it, F_1), \dots, L_n(\sigma_r + it, F_r)) \in A\},$$

$$A \in \mathcal{B}(\mathbb{C}^r),$$

and

$$\tilde{P}_{T,n}(A) \stackrel{\text{def}}{=} \frac{1}{T} \text{meas} \{t \in [0, T]: (L_n(\sigma_1 + it, \widehat{\omega}, F_1), \dots, L_n(\sigma_r + it, \widehat{\omega}, F_r)) \in A\},$$

$$A \in \mathcal{B}(\mathbb{C}^r),$$

both converge weakly to the same probability measure on $(\mathbb{C}^r, \mathcal{B}(\mathbb{C}^r))$ as $T \rightarrow \infty$.

Proof. The lemma easily follows Lemma 1, continuity of mappings $\tilde{h}_n : \Omega \rightarrow \mathbb{C}^r$ and $h_n : \Omega \rightarrow \mathbb{C}^r$ given by the formulae

$$h_n(\omega) = (L_n(\sigma_1, \omega, F_1), \dots, L_n(\sigma_r, \omega, F_r))$$

and

$$\tilde{h}_n(\omega) = (L_n(\sigma_1, \omega \widehat{\omega}, F_1), \dots, L_n(\sigma_r, \omega \widehat{\omega}, F_r)),$$

respectively, and of Theorem 5.1 from [2]. The limit measure in both the cases is of the form $m_H h_n^{-1}$. This follows from the invariance of the Haar measure m_H .

To pass from the functions $L_n(s, F_j)$ to $L(s, F_j)$, the following approximation is used. Let, for $\underline{z}_1 = (z_{11}, \dots, z_{1r})$ and $\underline{z}_2 = (z_{21}, \dots, z_{2r})$,

$$\varrho(\underline{z}_1, \underline{z}_2) = \left(\sum_{k=1}^r |z_{1k} - z_{2k}|^2 \right)^{1/2},$$

$$\underline{L}_n(\underline{\sigma} + it, \underline{F}) = (L_n(\sigma_1 + it, F_1), \dots, L_n(\sigma_r + it, F_r)),$$

$$\underline{L}_n(\underline{\sigma} + it, \omega, \underline{F}) = (L_n(\sigma_1 + it, \omega, F_1), \dots, L_n(\sigma_r + it, \omega, F_r)),$$

$$\underline{L}(\underline{\sigma} + it, \underline{F}) = (L(\sigma_1 + it, F_1), \dots, L(\sigma_r + it, F_r)).$$

Lemma 3. *Suppose that $\sigma_j > \frac{k_j}{2}$, $j = 1, \dots, r$. Then*

$$\lim_{n \rightarrow \infty} \limsup_{T \rightarrow \infty} \frac{1}{T} \int_0^T \varrho(\underline{L}_n(\underline{\sigma} + it, \underline{F}), \underline{L}(\underline{\sigma} + it, \underline{F})) dt = 0$$

and, for almost all $\omega \in \Omega$,

$$\lim_{n \rightarrow \infty} \limsup_{T \rightarrow \infty} \frac{1}{T} \int_0^T \varrho(\underline{L}_n(\underline{\sigma} + it, \omega, \underline{F}), \underline{L}(\underline{\sigma} + it, \omega, \underline{F})) dt = 0.$$

Proof of lemma follows from the corresponding one-dimensional statements, and from the definition of the metric ϱ .

Define one more probability measure

$$\tilde{P}_T(A) \stackrel{\text{def}}{=} \frac{1}{T} \text{meas} \{t \in [0, T]: \underline{L}(\underline{\sigma} + it, \omega, \underline{F}) \in A\}, \quad A \in \mathcal{B}(\mathbb{C}^r).$$

Lemma 4. Suppose that $\sigma_j > \frac{k_j}{2}$, $j = 1, \dots, r$. Then the measures P_T and \tilde{P}_T both converge weakly to the same probability measure P on $(\mathbb{C}^r, \mathcal{B}(\mathbb{C}^r))$ as $T \rightarrow \infty$.

Proof. Let θ be a random variable defined in a certain probability space $(\hat{\Omega}, \mathcal{F}, \mu)$ and uniformly distributed on $[0, 1]$. Define

$$\underline{X}_{T,n}(\underline{\sigma}) = \underline{L}_n(\underline{\sigma} + i\theta T, \underline{F}).$$

Then, by Lemma 4,

$$\underline{X}_{T,n} \xrightarrow[n \rightarrow \infty]{\mathcal{D}} \underline{X}_n, \quad (1)$$

where \underline{X}_n is the random element with the distribution P_n , and P_n is the limit measure in Lemma 4. After this, it is proved that the family of probability measures $\{P_n: n \in \mathbb{N}\}$ is tight. Hence, by the Prokhorov theorem, it is relatively compact. Thus, there exists a sequence $\{P_{n_k}\} \subset \{P_n\}$ such that P_{n_k} converges weakly to a certain probability measure P . In other words,

$$\underline{X}_{n_k} \xrightarrow[k \rightarrow \infty]{\mathcal{D}} P. \quad (2)$$

Define

$$\underline{X}_T(\underline{\sigma}) = \underline{L}(\underline{\sigma} + i\theta T, \underline{F}).$$

Then, in view of Lemma 5, for every $\varepsilon > 0$,

$$\begin{aligned} & \lim_{n \rightarrow \infty} \limsup_{T \rightarrow \infty} \mu(\varrho(\underline{X}_T(\underline{\sigma}), \underline{X}_{T,n}(\underline{\sigma})) \geq \varepsilon) \\ & \leq \lim_{n \rightarrow \infty} \limsup_{T \rightarrow \infty} \frac{1}{\varepsilon T} \int_0^T \varrho(\underline{L}(\underline{\sigma} + it, \underline{F}), \underline{L}_n(\underline{\sigma} + it, \underline{F})) dt = 0. \end{aligned}$$

This, (1), (2) and Theorem 4.2 of [2] show that

$$\underline{X}_T(\underline{\sigma}) \xrightarrow[T \rightarrow \infty]{\mathcal{D}} P.$$

Thus, P_T converges weakly to P as $T \rightarrow \infty$.

Repeating the above arguments for the random elements

$$\tilde{\underline{X}}_{T,n}(\underline{\sigma}) = \underline{L}_n(\underline{\sigma} + itT, \omega, \underline{F})$$

and

$$\tilde{\underline{X}}_T(\underline{\sigma}) = \underline{L}(\underline{\sigma} + i\theta T, \omega, \underline{F}),$$

we obtain that \tilde{P}_T also converges weakly to P as $T \rightarrow \infty$.

Proof of Theorem 2. In view of Lemma 4, it suffices to prove that P coincides with $P_{\underline{L}}$. For this, elements of the ergodic theory is applied.
